U.S. Consumers' Willingness to Pay for Food Labeled 'Genetically Modified'

Benjamin Onyango, Rodolfo M. Nayga, Jr., and Ramu Govindasamy

This study analyzes U.S. consumers' choice of cornflakes under five different labeling statements. Using a nationwide survey and choice modeling framework, results indicate that consumers value labeling statements differently, depending on the information contained on the label. The random parameter logit model results indicated that, compared to cornflakes that have no label information, cornflakes labeled "contains no genetically modified corn" have a value of 10 percent more, the label "USDA approved genetically modified corn" has a value of 5 percent more, and the label "corn genetically modified to reduce pesticide residues in your food" has a value of 5 percent more. The results also suggest that consumers negatively valued the label "contains genetically modified corn," paying 6.5 percent less, and the label "may contain genetically modified corn," paying 1 percent less than the product that has no label information.

Key Words: genetically modified foods, labeling genetically modified foods, random parameter logit model

Labeling of genetically modified (GM) foods remains a contentious issue. To date, there is no conclusive research on how GM food products should be labeled or if consumers in the United States would value such labeling information. Globally, countries are grappling to form a consensus on a harmonized, internationally acceptable system. However, given the influence of economic and political structures in various countries, it is more likely that we will see different labeling requirements in different regions or countries. For example, in the European Union (EU), regulations related to mandatory labeling of GM foods are already in place. In contrast, the United States has no mandatory labeling requirements pertaining to GM foods.

Evidence from public polls in the United States and elsewhere shows overwhelming support for labeling of GM foods. A recent national survey showed that 94 percent of U.S. consumers agree that food containing GM ingredients should be

labeled. Similar consumer surveys in France, Germany, and the United Kingdom suggest that about 90 percent of consumers would opt for mandatory labeling of beef produced from cattle fed on genetically modified crops (Hallman et al. 2003, 2004; Roosen, Lusk, and Fox 2001). It is possible that the clamor for labeling regulations arises from the public mistrust of GM food products. A study conducted by Hallman et al. (2004) showed that about 70 percent of the American public do not know that GM foods are tested for human safety, and that about three-quarters (76 percent) do not know that GM foods are tested for environmental safety.

While disagreements on a harmonized GM labeling policy persist, adoption of genetically modified crops worldwide is increasing (Figure 1). To date, 20 percent of global soybean, corn, cotton, and canola acreage is genetically modified. The leaders in the production of these GM crops are the United States, Argentina, Canada, and China (James 2003, Pew Initiative on Food and Biotechnology 2004). Due to increasing acreage allocated to GM crops in the United States, estimates suggest that between 60 and 70 percent of processed foods in U.S. supermarkets now include at least a fragment of a GM ingredient.

As of August 2001, 28 countries worldwide had passed some form of regulatory framework

Benjamin Onyango is Research Associate in the Food Policy Institute at Rutgers University, New Brunswick, New Jersey. Rodolfo M. Nayga, Jr., is Professor in the Department of Agricultural Economics at Texas A&M University, College Station, Texas. Ramu Govindasamy is Associate Professor in the Department of Agricultural, Food, and Resource Economics at Rutgers University, New Brunswick, New Jersey.

The authors thank anonymous journal reviewers and the editors for helpful comments and suggestions.

Figure 1. Global Area of Transgenic Crops (increase of 15 percent—9 million hectares, or 22.2 million acres—between 2002 and 2003)

Source: James (2003).

on GM foods (Phillips and McNeill 2000). These regulations include total bans on GM technology as well as mandatory or voluntary labeling. The voluntary labeling regime gives food producers the right to choose whether or not to label their products, as long as the labeling information is truthful and not misleading. On the other hand, a mandatory labeling regime would normally require that all products that contain genetically modified ingredients be clearly and prominently labeled (Caswell 2000).

While the United States, Argentina, and Canada have fully embraced GM crops, the EU has been relatively cautious. The EU's position on GM labeling may have to do more with ethical/moral considerations. Recent experiences related to mad cow disease and other food scares have also played a part in shaping the EU's GM labeling policy (Roosen, Lusk, and Fox 2001, Rousu and Huffman 2001). In contrast to the EU's approach, the U.S. voluntary labeling regime requires GM foods to be labeled if the food

has significantly different nutritional properties, includes an allergen that consumers would not expect to be present, or contains a toxicant beyond acceptable limits. Mandatory labeling regimes for GM foods have important and challenging implications. For example, mandatory labeling may require segregation imposed on the entire agricultural system, thus increasing the cost burden of providing information (Huygen, Veeman, and Lerohl 2003, Muth, Mancini, and Viator 2003). Consequently, GM labeling might cost the consumers, industry, and government to varying degrees (Huygen, Veeman, and Lerohl 2003, Caswell 2000, Runge and Jackson 2000). Golder and Leung (2000) showed that the cost of labeling might increase food prices by 10 percent in Canada.

A few studies have investigated consumers' willingness to pay for GM labeling. Most of the research on the subject has examined the advantages and disadvantages of implementation approaches and the likely corresponding costs

(Huygen, Veeman, and Lerohl 2003). In particular, support and opposition to mandatory or voluntary labeling regimes have been popular subjects of study (Rousu et al. 2004; Caswell 1998, 2000; Carter and Gruère 2003). Also investigated were topics relating to asymmetric information impacts on producers, government, and industry, as well as topics on label information prioritization (Huffman 2003, Fulton and Giannakas 2004, McCluskey and Loureiro 2003, Senhui, Fletcher, and Rimal 2003, Golan, Kuchler, and Mitchell 2000). Other studies have focused on language and label positioning (Hallman, Aquino, and Phillips 2003). A recent study by Carlsson, Frykblom, and Lagerkvist (2004) measured willingness to pay for mandatory labeling, voluntary labeling, or total bans of GM beef, pork, and eggs in Sweden. The findings of this study showed that GM foods can be a credence good that may cause market failure. Additionally, the study found that consumers are willing to pay a significantly higher product price to ensure a total ban on the use of GM food in animal fodder.

None of these studies, however, has investigated the effect of GM label statements on consumer behavior. Findings from recent focus group studies in the United States and research on GM labels in Canada have suggested that the wording on labels could have a significant effect on consumer understanding and acceptance of biotechnology (Hallman, Aquino, and Phillips 2003, Hu, Veeman, and Adamowicz 2005). There also are concerns as to whether consumers would use such labels (Li, McCluskey, and Wahl 2004, Teisl et al. 2003).

To fill this void, this study assesses consumers' choice of cornflakes under different GM label wording. In particular, this study contributes to the ongoing debate by assessing consumers' willingness to pay (WTP) for information provided by a GM label. In the following sections, we will discuss the survey methods, the empirical model, results, and conclusions.

Survey Methods

A survey instrument developed by the Food Policy Institute at Rutgers University was used to collect data for this study. The survey collected information on core questions related to Ameri-

can awareness and knowledge of GM foods, willingness to purchase GM products, attitudes toward risks and benefits, opinions on mandatory product labeling, and overall approval of the transgenic technique as it relates to animal and plant biotechnology. The Food Policy Institute contracted the opinion polling firm Shulman, Ronca, and Bucuvalas, Inc., to conduct 1,201 telephone interviews using computer-assisted telephone interview (CATI) technology.

Interviewers were consistently monitored throughout the field period. The interviews were conducted between May 4, 2004, and June 14, 2004.¹ To reduce interview time, the survey was split into two versions. The two versions shared core questions, but included different supplemental questions. Version A had 601 respondents and an average interview time of 19.5 minutes, and Version B had 600 respondents and an average interview time of 21.9 minutes. All interviews were conducted in English. Potential respondents were selected using national random digit dialing across the entire United States. U.S. Census Bureau population estimates determined the distribution necessary for proportionate geographic coverage. Appropriate weighting on age, gender, and race was done to correct for disproportionate representation.

The CATI program guided a random but balanced selection process to ensure that a representative number of males and females were interviewed. The CATI program is designed to work with the random sample already selected. To ensure representation in the interviewing process, the program makes reference to the number of males and females interviewed thus far and revises the next line of interviewees to accommodate the underrepresented gender to achieve the required balance.

Many of the telephone numbers originally selected as part of the sampling frame were excluded as non-residential or non-working numbers. Only 25 percent of the numbers selected at random yielded completed interviews. However, calls to 66 percent of the working residential numbers resulted in completed interviews. To

¹ No major events associated with biotechnology that could have influenced responses and therefore biased the results took place during the interviewing process. Additionally, the interviews were closely monitored for quality, and we believe that the period was adequate for successful completion of the process.

achieve the maximum response rate, many working numbers were attempted 16 or more times. Numbers were dialed on different days of the week and at varying times of day in an effort to reach elusive respondents. For households that used call-blocking systems, the research company allowed identifying information to be displayed. If an answering machine picked up three times in a row on any given number, interviewers left messages identifying the research company and the purpose of the call. When weighted, the 1,201 completed interviews had a sampling error of ± 3 percent.² For those questions asked of only half the sample, the sampling error increases to ± 4 percent. After completing the telephone survey, the 1,201 respondents were asked if they would be willing to participate in a follow-up mail questionnaire. The purpose of this follow-up mail questionnaire was to collect data relating to consumers' stated preferences about cornflakes and the consumers' trust in institutions associated with biotechnology. About 47 percent of the respondents (559) agreed to participate in the mail survey. These respondents were then mailed the questionnaire and \$5 as an incentive to return the completed questionnaire within 3 to 4 days. All the questionnaires were sent through first-class mail with a cover letter thanking the respondents for their participation. A follow-up letter with the questionnaire was sent to those who did not respond within 14 days after the first mailing. A total of 363 (65 percent) of the surveys were returned, of which 7 were incomplete (1 percent).

The previous focus-group research on labeling done by Hallman, Aquino, and Phillips (2003) and the study by Onyango, Govindasamy, and Nayga (2004) were the basis for deciding the product analyzed in this study. The product had to be readily available in stores, had to be familiar to a majority of consumers, and had to partly contain GM ingredients. Cornflakes were selected as the product based on these three factors.

One section of the mail survey was devoted to providing background information on genetic modification and labeling. In terms of background, the following information was provided:

- *Definition of GM.*³ Genetic modification as used in food production involves methods that make it possible for scientists to create new varieties of plants and animals by taking parts of the genes of one plant or animal and inserting them into the cells of another plant or animal. The process of genetic modification, often called transgenic transformation or DNA recombination, occurs when biochemists take desirable genes from one plant or animal and insert them into the genetic material of another plant or animal with the purpose of exploiting a trait from the original organism. This is sometimes called genetic engineering or biotechnology.
- *GM corn in the United States.* Currently, 40 percent of the corn grown in the United States is a genetically modified variety. This corn is approved by the U.S. Department of Agriculture (USDA) to be as safe for human consumption as the corn grown using traditional farming methods. Because genetically modified corn is sometimes mixed with traditional corn during storage and transport, food products that have corn ingredients (like cornflakes) may or may not contain genetically modified corn. The only way to know for sure if cornflakes are made from genetically modified corn or not is if the manufacturers put this information on their product's label.
- *Label information.* There are 6 types of special labeling information concerning the possible presence or absence of genetically modified corn in the cereal. The information should be viewed as entirely truthful. This information will vary for products A and B, but choice C will always have no special label. "No special label" means that there is no indication as to whether or not the cornflakes contain genetically modified corn. Please note that the initials "USDA" used on some of the labels means the U.S. Department of Agriculture.

² The sampling error associated with a nationwide sample of 1,200 people is approximately ± 3 percent with a 95 percent confidence interval. This means that if 50 percent of the respondents gave a particular response, the likely percentage of the entire adult population should be between 47 percent and 53 percent, 95 out of 100 times. The cooperation rate is the percentage of completed interviews (1,201) over completed interviews (1,201) plus refusals (636). A more rigid calculation of response rate, defined as the percentage of completed interviews (1,201) over total numbers of in-frame telephone numbers (3,120), yields a response rate of 38.5 percent.

³ This may include such transfers as bacterium inserts into the plant or animal.

A section of the choice modeling questionnaire provided instructions on choice selection. The instructions were as follows: "Carefully read and think about each question since you will be asked to select the box of cornflakes you most prefer out of three possible boxes of cornflakes. There are no right or wrong answers; we are interested only in your opinion." The choice modeling questions were pre-tested at Rutgers with suggestions to put "price" and "labeling statements" as row headings, and to put "survey instructions" at the top of the page.

The GM labeling statements used in this study were chosen based on extensive discussions and the GM labeling literature. The statements ranged from no information at all, to some information, to very detailed information about the label. The labeling information statements were framed in terms of label usefulness to the consumer decision making process (Caswell 2000). A fractional factorial experiment design was used to create a balanced and efficient design matrix for a number of choice sets. The product to be analyzed was characterized by two factors/attributes (i.e., label and price), each with six and five different levels, respectively (see Table 1 for details). The experiment yielded 32 choice sets. After removal of the dominated choices, 28 choice sets remained. Two of the alternatives in each choice set were all variants of a labeling and price variation scheme. The status quo alternative (no special label) was constant and common to all choice sets. The 28 choice sets were split (by blocking) into 4 subsets, with each respondent randomly allocated one set of 7 questions to complete.

The actual choice questions were presented in the following manner: "Imagine you are at the grocery store and want to buy a box of cornflakes. You have to choose among three boxes of cornflakes: A, B, or C. Which will you choose? You'll be asked to do this 7 times. While the combination of products may seem the same, they are all slightly different. Choose carefully and read all of the information given. By combining your choices with those of others, we will be able to better understand what is important to consumers" (see Figure 2 for an example). The cornflakes contain the exact same ingredients except that some contain genetically modified corn and some do not. The cornflakes differ from each other on the basis of price, the presence of genet-

cally modified corn, and special labeling information about the product. "The boxes are all the same weight and the cornflakes all look and taste exactly the same."

Sample Socioeconomic Characteristics and Response Rates to the Choice Modeling Questions

Table 2 shows that the composition of respondents in the sub-sample closely mirrors the main sample ($n = 1,201$) in terms of socioeconomic characteristics. Both samples show more female representation than male. Appropriate weighting was done as previously stated to ensure representation of the sample. Respondents' age ranged from 18 to 94, with those in the ages between 45 and 54 being relatively overrepresented in the sub-sample. Most respondents (90 percent) had completed high school. High school was the highest level of formal education for more than a quarter of the sample (26 percent). About a quarter (27 percent) had completed some college or an associate's degree, while 24 percent of the sample had completed a four-year college degree and 13 percent had earned a post-graduate degree. The remainder (8 percent) had not obtained a high school diploma. A little fewer than half (47 percent) had household income less than \$50,000, while the other half (45 percent) had household income greater than \$50,000.

Table 3 shows the distribution of respondents' answers to seven questions. The distribution of the choices shows substantial variation by block. For example, twice as many respondents in block 1 chose option A (56 percent) as compared to respondents in block 4. An equal number of respondents in each block chose option B. Respondents in block 4, compared to the other blocks, chose relatively more of option C (33 percent). Across the blocks, about 3 percent of the respondents chose not to respond.

Empirical Model

Consumers' choice of cornflakes under different labels is analyzed within the choice-modeling framework (Louviere, Hensher, and Swait 2000). This is done within the random utility discrete choice model framework (McFadden 1978,

Table 1. Cornflakes—Attributes and Levels

Attribute	Levels
Price levels	Current price (\$2.00)
	15% discount (\$1.70)
	10% discount (\$1.80)
	5% discount (\$1.90)
	5% premium (\$2.10)
Labeling	No special label (<i>Nospec.label</i>)
	Contains no genetically modified corn (<i>NOGMcorn</i>)
	May contain genetically modified corn (<i>MayGMcorn</i>)
	Contains genetically modified corn (<i>GMcorn</i>)
	Corn genetically modified to reduce pesticide residues in your food (<i>Reducepest</i>)
	USDA-approved genetically modified corn (<i>USDA</i>)

Based on the following information, which would you choose—
Box A, B, or C? Please place an X in one box only.

	Cornflakes A	Cornflakes B	Cornflakes C
Price	\$2.20	\$2.00	\$2.00
Special labeling information	"Corn genetically modified to reduce pesticide residues in your food"	"Contains genetically modified corn"	No special label
	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Figure 2. Choice Example

Revelt and Train 1998). Specifically, the study analyzes (i) how consumers value labeling information in their food choices, and (ii) differential valuation of labeling information by content (i.e., from no information to detailed information). Since market data (revealed preferences in actual market situations) for GM food labels are not

currently available, a survey instrument to elicit the consumers' stated preferences is used.

In this framework, the consumer is assumed to have a well-behaved utility function (i.e., with preferences that are complete, reflexive, and transitive). The consumer, therefore, is able to compare and rank alternative commodity bundles. In

Table 2. Socioeconomic Characteristics (%)

	Total sample (N=1,201)	Sub-sample (N=363) ^a
<i>Gender</i>		
male	37.9	36.4
female	62.1	63.6
<i>Age</i>		
18 to 24	11.0	8.5

^aThe choice modeling sub-sample.

relation to particular choice sets, the various options available are contained in a universal choice set S . A consumer may consider all or only a subset of these options or choose none of them. The Lancaster (1966a, 1966b) model provides the framework to analyze the consumer preferences. In this model, consumer i derives a total utility (U_{ij}) for choosing option j , from a finite set S . The composite utility function is given by

$$(1) \quad U_{ij} = V_{ij}(X_{ij}) + \varepsilon_{ij} = \beta_1 \text{Nospec.label} \\ + \beta_2 \text{NOGMcorn}_j + \beta_3 \text{MayGMcorn}_j \\ + \beta_4 \text{GMcorn}_j + \beta_5 \text{Reducepest}_j \\ + \beta_6 \text{USDA}_j + \beta_7 \text{Price}_j + e_{ij}.$$

The explanatory variables are the attributes (label statements and price; see Table 1) where V_{ij} is the deterministic part, which is a function of a vector, X_{ij} , consisting of choice-specific attributes

as well as individual specific characteristics (e.g., age, sex, etc.), and a random part ε_{ij} , which is unobservable. In the estimation process, we did not use any of the demographic variables.⁴ The random component is assumed to be independent of X_{ij} and follows some predetermined distribution. The consumer's decision process involves defining the choice problem, generating the alternatives, evaluating the attributes of the alternative, making a choice, and implementing (action), i.e., choosing alternative j if

$$(2) \quad V_{ij}(X_{ij}) + \varepsilon_{ij} > V_{in}(X_{in}) + \varepsilon_{in}; \forall j \neq n \in S.$$

The probability that the consumer chooses the option j is given by

$$(3) \quad \text{Prob}_{ij} = \text{prob}\{V_{ij} + \varepsilon_{ij} \geq V_{in} + \varepsilon_{in}; \forall j \neq n, \forall n \in S\}.$$

The model is implemented by making assumptions about the distribution ε_j . Assuming that ε_j are iid with type-I extreme value (Gumbel) distribution, the probability that the consumer i chooses option j is given by

$$(4) \quad P_{ij} = \frac{e^{\mu(\beta x_j)}}{\sum_{n \in S} e^{\mu(\beta x_n)}}$$

(McFadden 1973), where β is a vector of parameters to be estimated and μ is a scale parameter that is usually assumed to equal 1 so that the β 's can be identified. The vector β also includes a series of alternative specific constants (ASC) that capture the effects in utility from any attributes not included in X_{ij} (equation 1), which leads to the standard conditional logit model. However, the above model suffers from the restrictive *independence from irrelevant alternatives* (IIA) property, and therefore is unable to incorporate preference heterogeneity across consumers. To address this problem, we model consumer preference using the random parameter logit model (Brownstone and Train 1999, Louviere, Hensher, and Swait 2000, Bonnet and Simioni 2001). The random parameter logit model allows all choice-specific parameters to vary randomly across indi-

⁴ Taste heterogeneity in our model is attributable more to product attributes than to socioeconomic variables. Without loss of generality, their exclusion does not adversely affect our results.

viduals. That is, the β in equation (4) becomes β_i . It is further assumed that β_i is drawn from a joint density function, the parameters of which (the mean and standard deviation) are recovered by simulation.

The random parameter logit model assumes that consumers' choices are conditional on the specification of the distribution of the coefficients. Letting θ denote the distribution of parameter of coefficient β , the probability of individual i choosing alternative j is given by

$$(5) \quad \bar{P}_{ij} = \int P_{ij} f(\beta | \theta) d\beta,$$

where P_{ij} is as in equation (4) and $f(\beta|\theta)$ is the probability density function for coefficient β defined over a vector of parameter θ . The log likelihood function is given by

$$(6) \quad LL = \sum_{i=1}^m \sum_{j=1}^J D_{ij} \ln(\bar{P}_{ij}),$$

where D_{ij} is an indicator, which equals one if individual i chooses alternative j and zero otherwise. The integration expression in equation (5) cannot be efficiently estimated with maximum

likelihood estimation. However, the probability P_{ij} can be simulated according to the density $f(\beta|\theta)$. The parameters of the model in equation (1) are estimated using the Maximum Simulated Likelihood Estimator (MSLE) (Brownstone and Train 1999, Train 2002).

Results

The random parameter logit model results are presented in Table 4 and Figure 3. The estimated mean for price as well as the estimated means and associated standard deviations of the random attributes are reported. Also presented is the willingness to pay for the labeling statements, along with the corresponding 95 percent confidence intervals (i.e., the lower and upper bounds). The model was estimated with simulated maximum likelihood using the Halton draws with 250 replications, a simulation technique that uses non-random draws from the distributions to be integrated over, rather than random draws. By drawing from a sequence designed to give a fairly even coverage over the mixing distribution, fewer draws are needed to reduce simulation variance to an acceptable level. The overall model performance is given by the chi-squared test, which is significant at the 5 percent level.

The presence of the standard deviations of the mean values accommodates the presence of heterogeneity assumed in the random parameter logit model specification. The results show that the standard deviations of all the random attributes are highly significant with the exception of the labeling statement "may contain genetically modified corn," implying heterogeneity in preferences across the respondents. It can be observed that all the t-ratios for the standard deviations associated with the attributes are significant and show large differences. Of the significant standard deviations, the labeling statement "corn genetically modified to reduce pesticides" shows the largest variation, while the labeling statement "contains no GM corn" shows the least variation.

As discussed above, 559 respondents agreed to participate in the mail survey. Of these, 363 completed the survey; 7 surveys were incomplete. In this analysis, we used the 356 completed surveys. Although these surveys yielded 7,476 ($356 \times 7 \times 3$) choice sets, after removal of lexicographic

responses,⁵ 7,182 choice sets were actually analyzed (96 percent of clean choice sets). About 4 percent of the respondents were lexicographic—i.e., those respondents who would choose neither A nor B regardless of the attributes. Therefore, inclusion of lexicographic respondents will not be amenable to choice modeling since explaining their choices on the basis of attribute levels (the basic premise of choice modeling) would produce biased estimates.

The results show both negative and positive labeling valuations on the choice of cornflakes. The negative valuation for a label statement implies that moving from the conventional label (the current position, i.e., no label) reduces consumer utility. Conversely, those labeling statements that were positively valued imply increasing consumer utility, consequently improving consumer utility in making a decision related to the cornflakes. In such a situation, consumers are willing to move from their current positions towards positions providing more information on the foods they choose to buy or consume.

The (WTP) values were estimated by evaluating the ratio of the labeling statement coefficient to the coefficient of price.⁶ For example, the distribution of the labeling statement "contains no genetically modified corn" has an estimated mean coefficient of 2.3246 and an estimated standard deviation of 2.6977. Given the estimated price coefficient of $-.1146$, the model implies a mean of 20 cents or \$0.20 willingness to pay for such information with a standard deviation of 24 cents (\$0.24). Given the assumption of normal distribution for the labeling statements, about 18 percent of the consumers placed a negative valuation on the labeling statements "contains no genetically modified corn."

Positive mean willingness to pay was associated with the following labeling statements: "contains no genetically modified corn," "USDA-

⁵ The removal of the lexicographic preferences also accounts for those respondents who opted for C in all of their repeated choices, on account of the fact that they were uncertain about the product. In our analysis we have excluded such responses. As a result, our definition and analysis are based on those responses making use of the variation in attributes (i.e., the content of the labeling information in making their choices on the product).

⁶ Given the indirect utility function (equation 1) $v = \beta'x = \sum \beta_j x_j$, the WTP is given by $(dv/dx_i)/(dv/dx_j)$, where the numerator is the attribute and the denominator is the price, thus the WTP equals $-(\beta_i/\beta_j)/100$ converted to dollars.

Table 4. Parameter Estimates: The Random Parameter Logit Model (normally distributed random parameters)

Variable		Coefficient	t-ratio	p-value
Price		-0.1146	-3.89	0.00
Contains <i>no</i> genetically modified corn	mean coefficient	2.3246	9.94	0.00
	standard deviation of the coefficient	2.6977	10.43	0.00
May contain genetically modified corn	mean coefficient	-0.2293	-1.12	0.26
	standard deviation of the coefficient	2.4128	10.50	0.00
Contains genetically modified corn	mean coefficient	-1.5020	-5.16	0.00
	standard deviation of the coefficient	3.2473	9.66	0.00
Corn genetically modified to reduce pesticide residues in your food	mean coefficient	0.8386	2.73	0.01
	standard deviation of the coefficient	5.3254	10.87	0.00
USDA-approved genetically modified corn	mean coefficient	1.0459	3.26	0.00
	standard deviation of the coefficient	4.9918	8.10	0.00
Model Statistics				
Log likelihood		-963.21		
Restricted log likelihood		-1386.29		
Chi square		846.17		
DF		39		
Mean Willingness to Pay				
	Mean	Std Dev.	Lower Bound	Upper Bound
Contains <i>no</i> genetically modified corn	20.29	23.54	-26.79	67.38
May contain genetically modified corn	-2.00	21.06	-49.08	40.11
Contains genetically modified corn	-13.11	28.34	-60.19	43.57
Corn genetically modified to reduce pesticide residues in your food	7.32	46.48	-39.76	100.27
USDA-approved genetically modified corn	9.13	43.57	-37.95	96.26

approved genetically modified corn,” and “corn genetically modified to reduce pesticide residues in food.” Consumers’ willingness to pay for the labeling statements may also suggest public trust and confidence in government regulatory agencies. In this respect, the USDA-approved label statement may be seen as conveying product safety and may therefore enhance public acceptance of the GM food.

On the other hand, the labeling statement “may contain GM corn,” although insignificant, may be seen as not providing any meaningful information to the consumer. Therefore, it is not a good signal to aid decision making. The results show that consumers were willing to pay for more information on the label; i.e., they were willing to pay 20 cents more for the cornflakes with a label clearly

stating that the product contains *no* GM modified corn, almost 10 cents more for a cereal that has been approved by the USDA, and 7 cents more for cornflakes bearing a label stating that the genetically modified product reduces pesticides in the food. The results also show how much it will take consumers to accept certain labeling statements. Consumers will require a discount of 1 percent for the statement “may contain GM corn” and a discount of 6.5 percent for the statement “contains genetically modified corn.”

Conclusions

This paper examines consumer attitudes towards GM foods and the trade-offs made between la-

Figure 3. Labeling Statements—Mean Willingness to Pay

beling statements for GM foods. The results of this study show that the choice modeling experiments provide a way of valuing labeling statements by facilitating consumer choice, thus giving some direction as to what consumer preferences will be if GM products are labeled in a particular manner. Consumer preference for labeled GM cornflakes is influenced by the nature of information conveyed by the different labeling statements. Results generally suggest that statements that inform the consumer about product certification and benefits are valued positively. On the other hand, statements that indicate only the possible presence of GM are valued negatively. Consumer' willingness to pay a premium for certain label statements such as "contains no GM corn," "USDA-approved GM corn," and "corn genetically modified to reduce pesticide residues in your food" shows that there is a potential market for labeled GM foods. The differences in the valuation of the statements also imply that some statements are preferred to others.

The information generated by this study can be used as a guide for the food industry and government in the design of possible labeling schemes that can add value to consumer choice of GM foods. Future studies, however, should replicate the present study to assess the robustness of these findings. The studies should consider other

labeling statements not included in this study. Additionally, it may be worthwhile to carry out a cost-benefit analysis on voluntary and mandatory GM labeling schemes.
