Logistics Analysis of the Pathogen Control Provisions of the Almond Marketing Order

Victoria Salin

Abstract

The Marketing Order for California almonds was amended in 2007 to enhance food safety. Around 400-500 million pounds of almonds undergo an added step in processing to reduce risk of salmonella contamination. This paper reports on the logistics necessary for implementing the program. We use a linear programming model and assess the uncertain costs of transportation and the risks related to regulatory approval of certain pasteurization technologies. The total cost of treatment and the associated logistics is approximately $28 million per year. Capacity for treatment is adequate. The pricing of out-sourced treatment services is the main driver in the cost estimates.

Keywords: Production; cost; capital, total factor, and multifactor productivity; capacity
Introduction

Production and exports of almonds increased over the last decade, aided in part by the successful positioning of almonds as healthful and nutritious alternatives for snacking and in recipes. The industry’s promotion efforts were threatened by two incidents, in 2003 and 2005, when salmonella contamination was discovered. In response to the contamination and the associated outbreaks of illness, the Almond Board of California sought an amendment to its Marketing Order, which required handlers to assure treatment for pathogen control.\(^1\) The salmonella control Action Plan, referred to as “pasteurization,” went into effect in September 2007.\(^2\)

While the almond industry's Action Plan is unique in many respects, this industry is not alone in facing questions about the costs of the measures intended to prevent food contamination. Since the almond recalls, peanut products and pistachios have experienced product recalls (Martin and Moss; Funk; Wittenberger and Dohlman). And like the almond industry, pistachio producers used the Marketing Order mechanism as the legal structure for a common safety practice (Sumner, et al.) Thus this analysis of the logistics of compliance has wider relevance in the economics of food protection, particularly where technology and the nature of the product permits a treatment protocol for pathogen reduction.

Pathogen control for almonds involves the introduction of a new processing step into the value chain at the handler level. The numerous farms that produce almonds in California are not directly affected by the pathogen control program. The processing firms (handlers) are subject to the Marketing Order. Almonds are hulled in the field, and then the in-shell nuts are transported to handlers for shelling and intermediate processing.

There are several alternative ways in which pathogen control activities are integrated into the logistics of handling. Some handlers conduct the pathogen-reduction treatment in-house, then establish separate inventories of treated and untreated products. Other handlers use off-site treatment, which requires that inventory be separated in addition to the loading and transportation of untreated product to the treatment facility. The treatment can be undertaken on bulk bins of product or on pallets of case-packed product, depending on the technology of the treatment operation. Fumigation, for example, is typically on bulk bins. Steam application is either applied to loose product on conveyors or to plastic-wrapped pallets, depending on the technology. After treatment at an off-site facility, the almonds may be shipped directly to customers or returned to the handler for storage until an order is received.

Some value-added processing steps that are standard practice for almonds effectively pasteurize, therefore little change in the logistics is required for those items. Blanching and oil roasting are examples of processes that can achieve pathogen control standards with modest modifications to

---

\(^2\) Pasteurization has a specific definition to food scientists and FDA regulators in terms of percentage pathogen reduction. In this paper, the term pasteurization is used more generally as a synonym for the terms treatment and pathogen control.
the time or temperatures used. For these product forms, relatively modest changes in the system are needed.

Exported goods experienced the least change in the value chain after the Action Plan. The Marketing Order does not cover almonds exported outside North America. Several handlers export their entire production and need no treatment process.

In the almond industry, where the demand for pathogen control is established by the Action Plan, the decision to “make or buy” treatment services is a key influencer of strategic positioning over the long term. The industry committee responsible for developing the Action Plan expected that the availability of treatment services for hire would enable smaller handlers to comply without making substantial capital investments. Thus the analysis of capacity for treatment is important to understand implementation of the almond industry program.

Pathogen Control and the Market for Treatment Services

The Almond Board of California (ABC) implemented its pathogen control program in collaboration with FDA and various private sector experts so that treatments provide the necessary reduction in salmonella (4-log reduction). Moreover, ABC’s rules and procedures provide oversight that the companies in the industry are in compliance. These rules effectively establish a demand for food safety expertise that did not exist prior to the change in the Marketing Order. The different roles of agents in establishing a credible system can be understood with the following brief description of the pathogen control program.

Process Approval

A treatment process needs to be validated in terms of its technology to accomplish a 4-log reduction in salmonella. The validation of technology requires an investment in time, expertise, testing, and the management of the approval process with FDA. Approved technologies include oil roasting, dry roasting, blanching, steam processing and propylene oxide (PPO) fumigation. The Almond Board of California assists in obtaining approvals and assembles an expert review panel to aid in the development of additional acceptable treatment technologies. Apart from salmonella control, a series of quality issues relating to hardness, flavor, effects on brown skins or color of blanched product, and more have been studied in an effort to broaden the choices of pasteurization processes that are acceptable from the point of view of safety and food quality.

Technology Validation

For either a new treatment facility or an existing process, operators must demonstrate scientifically that the equipment in operation satisfies requirements of the Action Plan. Third party experts are usually hired to do this and the documentation of the validated technology is provided to ABC.
Audit the Pathogen Control Plan

Handling companies develop a plan annually for treatment of the crop and are subject to audits to verify that the activities are taking place. The auditing services are procured from the certification agency DFA of California.³

Supply, Demand, and Pricing of Almonds

Since the adoption of the salmonella control Action Plan in 2007, almond production rose by 14%, to 1.6 billion pounds in the 2008/2009 crop year (ending July 2009) (Almond Board of California). North American shipments subject to the Action Plan regulation increased by 4%, to 451 million pounds in the 2008/2009, crop year. The remaining amount, approximately one billion pounds, is exported outside North America and is exempt from the treatment requirement. More than half of California almond production is exported each year; the leading destinations by volume are Spain, Germany, and China.

Farm prices of almonds fell consistently since 2005 along with the rapid increase in production. The grower price was less than $1.50 per pound in crop year 2008/2009, down by 50% from the peak in 2005/06.

The downturn in prices affects the economic impact of the pasteurization rules, according to some business metrics. As an example, assume that the total cost of treatment and the associated handling/management is approximately 10 cents per pound. In a year in which prices of almonds are high, say $2.50 per pound as they were in 2005/2006, the impact of the program in terms of share of farm price is 4%. When market prices are down to $1.50, the burden of the pathogen treatment in terms of per-pound value is significantly higher, 6.7%.

Almond exports rose consistently during the last several years (Figure 1). In some years, exports grew significantly faster than domestic shipments. The growth trend in exports has served as a relief valve on the total costs of the Action Plan because most exports are exempt.

Almonds are prepared in a variety of ways to meet differentiated demands among final consumers worldwide. The bakery and confectionary industries purchase almonds in whole or blanched forms and further process them into sweet baked goods, candies, breakfast cereals and snack bars and mixes. Some handlers, typically the larger operations, conduct a full range of processing within their businesses and deliver consumer-packaged-goods to retailers or distributors. Some consumers demand organic or raw foods and several handlers are specialized in serving organic product niches. Other handlers provide both organically-grown and conventionally-grown nuts.

Given the various preferences and requirements of the highly differentiated consumer markets, handlers must establish specifications for production and, now, standards for pathogen reduction treatments, to meet a wide range of dimensions in terms of quality. For example, quality to certain customers means timely fulfillment of a large order of consistent size product, to be used for further processing. To another customer, quality is intact brown skins for goods that are

³ DFA of California is also known as the American Council for Food Safety and Quality.
meant to be sold whole, in a natural or organic product line. Treatment of almonds with heating processes has been perceived as an impediment to meeting certain quality specifications. There is a risk that flaking of almond brown skins might result from heat or steam. Further, for a very small niche of consumers who select almonds as a raw food item, any form of heat treatment is not acceptable.

![Figure 1. Growth in almond production, exports and grower prices, 1995-2008.](image)

Source: NASS. 2008/09 is forecast
Note: Dollar values in the figure are the season average grower price received in the year

A further dimension of quality is accuracy in terms of records regarding the processes that the goods have undergone. Subsequent to the Action Plan, domestically shipped almonds must be certified as treated. Or, if they have not been treated, they must be labeled “unpasteurized” and shipped outside North America or to a customer that has been approved to conduct pasteurization in its processes.

The availability of approved, validated treatment facilities was disrupted when a particular equipment vendor’s technology that seemed promising in 2006 failed to achieve the 4-log pathogen reduction required by FDA. The inability of the Ventilex technology to be approved was a major blow to investors and to the nearby handlers that had planned to use Ventilex as their out-source treatment facility.

**Least–Cost Treatment Transportation Plan**

An economic model of logistics costs, including shipping, handling, and treatment, is used to develop the least-cost plan from an industry-wide perspective (Bazaraa, Jarvis, and Sherali). The
main goals of the model are to identify capacity constraints, if any, and to analyze the effects of possible changes in energy costs on the future implementation of the almond industry Action Plan.

The availability of treatment capacity is a critical issue that affects the costs of implementing the almond industry’s food safety Action Plan. To avoid the possibility of bottlenecks in accessing treatment services, some of the largest handlers invested in on-site treatment facilities. A large number of handlers, many of them smaller businesses, depend on outsourcing arrangements for the required pathogen-reduction treatment. Scenarios that may affect the total cost of the program are examined, including changes in fuel prices, potential production growth in the industry, and the failure of a technology to provide adequate pathogen control.

A linear programming (LP) model is used to represent the geographic patterns of production and treatment and identify the routes that minimize total transportation costs from handlers to treatment facilities and then from treatment facilities to shipping points. The constraints reflect product flows as of the 2006/2007 crop year. The 100 handling companies were aggregated into supply points of origin according to ZIP codes. The largest handlers (those shipping more than 5 million pounds per year) were the starting point for creating supply regions. Some of those large handlers share a ZIP code with another handler and were combined into the same supply location (leaving 20 source points in the model). The distances combined within a source region are typically 20-35 miles.

The location of 16 treatment facilities is based on data provided by the Almond Board of California (ABC); capacity is estimated from discussions with industry sources, including vendors of technologies. Final destination points are represented as East Coast USA, two California locations, Canada, and Mexico.

The objective function is:

\[
\text{Minimize Cost} = \sum_i \sum_j C_{ij} X_{ij} + \sum_j \sum_k C_{jk} X_{jk} + \sum_i V_j X_{ij}
\]

where \( i = 1, 2, \ldots, 20 \) handlers, \( j = 1, 2, \ldots, 16 \) treatment facilities, \( k = 1, 2, \ldots, 5 \) shipment destinations, shipping to New York (for East Coast USA & Europe), San Francisco (for West Coast USA & Asia), Long Beach (for West Coast USA & Asia), Mexico, and Canada.

Variables are:

- \( X_{ij} \) quantity of almonds transported from handler \( i \) to treatment facility \( j \)
- \( X_{jk} \) quantity of almonds transported from treatment facility \( j \) to shipment destination \( k \)
- \( C_{ij} \) transportation cost from handler \( i \) to treatment facility \( j \)
- \( C_{jk} \) transportation cost from treatment facility \( j \) to shipment destination \( k \)
- \( V_j \) variable costs of treatment facility \( j \)
The constraints are the standard set for supply at handler locations, capacity at 16 treatment locations, and demand at 5 demand centers. Solutions were obtained using GAMS (General Algebraic Modeling System) MINOS solver.

The linear program modeling framework has several embedded assumptions and limitations. One important limitation is that logistics choices are assumed to be made with the goal of cost-minimization alone. To that extent, other non-monetary factors that affect the decision to select a treatment location are overlooked. For example, with this model, one cannot analyze the possibility that customers choose a treatment location for reasons related to the type of technology, service levels, or proprietary decisions.

The assurance processes that lead to high quality products generate transactions costs that are difficult to price in a market exchange. Unobserved costs include the “hassle factor,” the time and energy of staff in arranging for the approvals or audits, or the unwillingness of customers to make a transaction because of concerns about reputation or quality. These are not included in the model.

Another important assumption is the absence of economies of scale. That is, costs are assumed to be accurately modeled on the basis of a charge per-mile or per-pound and there are not significant overheads or sunk costs. This assumption is standard in transportation analysis and is supported by industry sources as applicable for this study.

The cost of shipment from treatment providers to destination points is excluded from the total costs reported in this study, because even in the absence of the Action Plan, almonds would have been shipped to those destinations. Transportation from the handler to the treatment location and the variable charges of treatment services are included in the total cost estimate.

Treatment facilities included in this model use fumigation technology (poly-propylene oxide), blanching, oil roasting, steam, and moist heat treatments. The cost of treatment used is an average of the expected charges; there is no differentiation in pricing for different types of technology or for individual businesses’ policies.

Data and Baseline Parameters

The baseline volume of 502.5 million pounds was determined from the 2006/2007 crop year shipment records and includes the almonds that were destined for North American customers in that year (Table 1). Almonds exported outside of North America (821 million pounds) are not subject to the treatment requirement, hence are not included in the estimate of logistics costs.

A portion of the almond crop is shipped domestically without treatment because the almonds are delivered to a user under the Direct Verifiable (DV) program. Under the DV program food processing companies (40 different premises and 24 firms) were approved to receive untreated almonds on the basis that their production processes provide pathogen control. The actual levels of DV shipments are proprietary information. We assume in the baseline model that a relatively small share of the crop is shipped under the DV program (110,000 pounds). This assumption, if incorrect, will tend to overestimate the costs of the Action Plan. The rationale for a conservative
size of the DV program is that there are no published sources on the volume shipped under the program and industry sources were not available to provide defensible estimates.

Baseline cost parameters are $2.70 per gallon of diesel fuel, $13.50 for truckers’ hourly wages, and maintenance expenses of 9 cents per mile. The fuel economy is fixed at 7 miles per gallon. Treatment charges are set at 5.5 cents per pound of almonds for all technology types and locations.

Results of Logistics Analysis

The total logistics cost associated with the food safety Action Plan is an estimated $28 million per year. Cost efficiencies are obtained because the largest handlers have access to treatment facilities on their own premises, or nearby. Low-cost transportation is a competitive advantage to those almond handling firms that have invested in on-site treatment. Investments in treatment facilities that several handlers have made contribute to system-wide efficiency in terms of transportation costs. Other handler firms that have not invested in on-site treatment, but are located near a service provider, also benefit from low-cost transportation.

The findings indicate that:
- Capacity of treatment is not a limiting factor.
- Charges for outsourced treatment are the largest contributor to total cost of the Action Plan.
- Diesel fuel costs rising to historically high levels adds less than 1% to the total cost ($290,000).

Capacity for pathogen-reducing treatment of almonds is more than adequate for the industry’s needs. Even excluding the Ventilex systems from total capacity due to the failure to attain regulatory approval, there is sufficient treatment access in terms of industry-wide needs. More than 320 million pounds of treatment capacity goes un-used. Four of the fourteen different treatment
locations have excess capacity. These results are strong indications that treatment is adequately distributed in the California almond industry.

The North (Chico area) and Central regions (Modesto area) are not capacity constrained, even under the assumption that Ventilex is shut down and not replaced. However, in the Sacramento region, total capacity is insufficient to meet the demand. The optimized logistics model indicates that treatment facilities in the regions north and south of Sacramento are used when Sacramento hits full capacity. Those alternative routes each exceed 100 miles.

The marginal benefits of additional capacity at two treatment locations (Wasco and Lost Hills) are among the highest. That is to say, there is an incremental benefit from locating capacity in these regions. Part of the reason is the large volume of almonds that are supplied by handlers in these locations. If there were more capacity, modest savings in transportation costs would be expected. At the margin, a one-pound increase in capacity in these locations leads to transportation cost savings of 60 cents.

**Impact of Regulatory Approvals on Capacity Constraints**

When the Action Plan went into effect, several treatment facilities were operating under temporary approvals, as appropriate for the implementation phase of the regulation. During 2008, three of the treatment facilities using Ventilex steam technology failed to meet final approval for satisfactory pathogen-reduction performance.

The baseline results reported in this study do not include the Ventilex facilities. As a test of the impact of removing that capacity from the system, a model was developed in which Ventilex facilities are included, which was actually the case in the 2007 crop year. Treatment capacity increases by 162 million tons with the inclusion of these facilities, and the impact on total cost is minimal. Total cost falls by $40,000, or by less than one percent (0.14%). The cost per pound treated was held constant in both versions of the model; therefore, changes in location alone explain the estimated modest change. With Ventilex facilities in place, a route of more than 150 miles from region 4 to region 3 is no longer necessary and the shadow price of capacity limits at the two facilities in region 4 is reduced.

It should be noted that the logistics model does not represent the firm-level impact of the lack of access to Ventilex technology. There are adjustment costs in finding an alternative arrangement for treatment, particularly if a handler’s customer requirements did not allow the use of another form of treatment technology nearby.

**Charges for Treatment Services**

The total cost of the Action Plan logistics is highly sensitive to the charges for treatment that are assumed. Lacking detailed data on charges for treatment, we use a constant cost per pound treated for each treatment facility, regardless of technology and location. This assumption is consistent with a competitive market for treatment services. Each additional penny in the average per-pound charge for treatment generates $5 million more in total logistics costs (Table 2).

Fuel Prices

As a starting point, the baseline model has diesel fuel price at $2.70 per gallon. This was the average price in California during 2003-2009, according to the U.S. Department of Energy. Diesel prices ranged from $1.10 per gallon in February 1999 to $4.97 per gallon in July 2008, then fell to $2.30 per gallon in early 2009 (Table 3). The sensitivity of the logistics costs to diesel fuel prices is relatively low. If diesel fuel is included at $4.97 per gallon (the July 2008 peak), total costs rise by $290,000.

Conclusions and Discussion

An economic model of an efficient logistics system for treatment of almonds indicates that total capacity is adequate to treat all the almonds shipped to North American customers. Costs of the treatment and related logistics are estimated at approximately $28 million per year.

Energy costs have a relatively small effect on the total cost. If diesel prices return to the high levels of the summer of 2008, the increase in the total cost of transportation is expected to be less than $300,000. Given the modest impact of diesel fuel, attention should be focused on the charges for pathogen-reduction treatment as the driver in total cost of the Action Plan. The majority of handlers depend on outsourcing to custom providers to treat their products. The most efficient locations for treatment are the largest handlers’ operations, and it is important to know
whether services are offered on a for-hire basis in ways that meet the needs of the smaller handlers. Clearly, an economically efficient treatment industry is an important goal. Treatment services are not “one size fits all,” and as in most differentiated markets, pricing issues are complex. Is monitoring the competitiveness of the market for treatment services a role for industry, for USDA, or for FDA?

Food contamination incidents since the adoption of the Action Plan have reinforced the value of a proactive system to reduce contamination risks industry-wide. Peanuts, and now pistachios, have been implicated in salmonella incidents. According to the Almond Board of California,

> “Product recontamination was a contributing factor in a number of product recalls of other nuts in 2009. ABC acted quickly to develop the Plant Environmental Monitoring Program (PEM), which is an important tool that hullers/shellers, handlers, DV users, and manufacturers can use to help control product recontamination. A well-thought-out PEM will help to significantly reduce the risk of product recontamination in a processing operation.” (ABC, Almanac 2009: 18).

The experience of the almond industry demonstrates that regulatory risk is a factor in the efficient deployment of safety-enhancing technology and services. Industry is investing in technologies under the expectation that the systems will satisfy technical standards, and there are real possibilities that the systems in place may not perform as expected. While the impact of the approval problems in this industry-wide model was modest in terms of capacity constraints, the particular firms involved had to make adjustments to find alternative treatment providers.

Another issue related to technology results from the differentiation of consumer demands in the market. Some processes are not acceptable to certain customers, even if they accomplish pathogen control. As a result, the market for treatment services must be differentiated as well. For example, a custom provider that can offer pathogen reduction services without fumigation can meet the requirements of organic food producers and consumers. There will be some potential for differentiation and possibly profit-making as treatment service providers find ways to attract specialized customers who will pay for premium-priced services in association with the premium-priced final goods.

In assessing the developing market for safety-enhancing services, economists have much to offer. It can easily be established that some mark-ups in the pricing of treatment services are simply cost recovery; justified by the complexity of bringing in small lots from many different handlers. Another valid reason for differentials in charges across types of treatment is that some markets with high willingness to pay for quality will be able to sustain higher charges for the form of treatment that is acceptable to those customers, leading to a premium price at the treatment facility.

As the market for pathogen control services matures, one could expect that competitive forces would affect the supply and demand for treatment services. Handlers requiring custom treatment would be able to choose between alternative providers on the basis of location, service provided, and timeliness. And, if the competition were vigorous, one would expect an equilibrium at which treatment suppliers price their custom services to cover their cost, not to be a profit center.
Such a competitive market will develop more quickly if there are few constraints on the scientific expertise needed to assure the qualifications of service providers.
