Data Appendix for the Article Entitled “Determinants of World Demand for U.S. Corn Seeds: The Role of Trade Costs”

Sampath Jayasinghe, John C Beghin, and GianCarlo Moschini
Iowa State University
In *American Journal of Agricultural Economics*

This appendix provides description of the data sources, a copy of the data tables (also available in excel format) and the simple regressions used to derived expected prices of corn in various countries. The variable definitions are included in the excel file.

Data Sources

The U.S. seed corn export data are based on Foreign Agricultural Trade of the United States (FATUS) from the USDA, which reports both value and volume. Under FATUS, volume is derived from value divided by the unit value of the largest seed category. We found some irregularities in the volume data reported in FATUS. Hence, we transformed the seed export value (US\$) into quantities (metric tons) using the U.S. seed corn price in respective years as the average export unit value. This step provides quantity data that are consistent with the value data and that are quality adjusted, as the export volume is expressed in the same volume unit for every country. The U.S. seed corn quantities and prices are from the Economic Research Service, USDA. Annual seed corn production in the United States is calculated by adding total exports of U.S. seeds to the estimated total domestic (U.S.) use of seeds.¹ Annual U.S. domestic use of seed is assumed to be equal to corn planted acres times the seed rate as assumed by USDA. Corn planted area for all purposes is taken from the National Agricultural Statistics Service (NASS), Agricultural Statistics Board, USDA. Average seeding rate per acre for corn is based on data from Cropping Practices surveys and

¹ When estimating trade share by country, we compute shares based on total seed use for countries included in the sample, and hence shares do add up to one.

the Agricultural Resource Management Survey (ARMS), Economic Research Service, USDA. The U.S. corn seed use data are by calendar year.

The seed export data are based on the calendar year. We concentrate on 1989 to 2004 because of the limited export data availability in FATUS. Our final country sample consists of 48 countries based on the following criteria. This sample was selected based on an average minimum corn production of 1 million metric tons (mmt) per year, including seed corn and forage, during the time period of the study. Australia was added to the sample because it has very restrictive corn seed regulations, although its corn production is smaller than 1 mmt. Total world corn production and each country's corn production are based on the Food and Agriculture Organization of the United Nations FAOSTAT.²

The FAOSTAT provides production data on Seed Maize (HS code: 1005) as well as Maize for Forage and Silage (HS code: 1214.90). Growers buy hybrid corn seed to produce silage just as they would to produce corn for other purposes. We found inconsistencies between large seed net imports and small corn outputs reported under HS 1005 in some countries in the FAOSTAT data. Notably, we found that Japan, the United Kingdom, and the Netherlands have sizeable imports of corn seeds but no significant seed maize production in the FAOSTAT data. Most of these countries use corn for silage instead of maize. Given these facts, we account for the corn production for silage as being relevant for the overall demand for seed corn. To aggregate these two types meaningfully, we use 8 bushels of grain maize per one ton of silage to get units in green maize physical equivalent. Corn production data are by calendar year. Our original country sample consisted of 54 countries. We deleted Belarus, Moldova, Kazakhstan, and the Russian federation for which we found some irregularities (wide unexplainable swings) in corn production data that could

² World corn output here is the sum of corn production in countries included in the sample so as to be consistent with the definition of trade shares.

not be reconciled using other data sources. We also deleted Malawi and Nigeria, for which data were incomplete.

As noted earlier, in our framework the expected producer price of corn is assumed to approximate the (unobserved) unit cost of corn seed production under the assumption of perfect competition in corn production and CRTS. We obtain the expected price by regressing the corn price of each country on the lagged U.S. corn price including time trend and then getting the predicted values. The current producer price is by calendar year and based on the FAOSTAT.

Tariffs applied to U.S.-sourced corn seeds are based on World Bank's World Integrated Trade Solution (WITS) database (see Table 7 in the Data Appendix). Tariff data are currently limited to 1996-2004 in WITS. Hence, we found some pre-1996 data from the Trade Analysis and Information System (TRAINS) database and Agricultural Market Access Database (AMAD). We use whatever data are available for 1989-1995 in TRAINS or AMAD and backtrack to 1989 assuming the same value for missing information. Tariff data are by calendar year.

Direct air distance between the U.S. and the major financial capital of each country is based on the World Distance Tables from the Inter-University Consortium for Political and Social Research (ICPSR) database. We use the log of air distance between the two major cities of the respective countries as the proximity measure. The cities are usually the capitals of the two countries. But we substitute the capital for a major city in a few cases, as the major city seems to be the country's economic center. For example, we use Shanghai for China rather than Beijing. Distance is set equal to zero for the United States.

The number of SPS regulations imposed by the importing country is based on data from the Export Certification Project Demonstration (EXCERPT) database maintained at

Purdue University on behalf of USDA APHIS. The SPS regulations for each country are updated in 2006 by the EXCERPT. However, older regulations starting from 1996 are reported in the EXCERPT archives. We look at phytosanitary certificates, import permit, and field inspection as well as some other demanding regulatory requirements, including seed testing, post-entry testing, and quarantine. Virtually all countries require a phytosanitary certificate, except Canada. Australia and China have a seed import ban, although China has imported a small amount of seeds in recent years. Some seed lines have to be imported by China to initiate local production. Hence, the Chinese trade ban has not been as tight in recent years, although seed imports remain very small relative to the size of the Chinese corn sector. We use a large number for the SPS count (prohibitive SPS compliance cost) for China and Australia to mimic an SPS count equivalent to the bans.

Over time, most countries have streamlined their SPS regulations. Argentina and Chile have a low SPS count. The most radical simplifications have occurred in some Eastern European countries, which are now members of the European Union (EU). Notably, in the last 10 years, Hungary started with an SPS count of 68, streamlined it to 30 in 2003, and eventually adopted EU regulations (SPS count of 3) with EU accession in 2004. South Africa, India, and Indonesia also simplified their regulations by removing all SPS requirements. Egypt, Zimbabwe, and, surprisingly, Brazil have very high SPS counts. The Brazilian case is puzzling, as the country is a large corn producer that would benefit from accessing better seeds.
