Laboratory Evaluation of Promising Compounds as Repellents to Flour Beetles, Tribolium Spp.

Marketing Research Division

Agricultural Marketing Service

U. S. DEPARTMENT OF AGRICULTURE

PREFACE

This report is based on a study of various chemicals as repellents for possible use in insect-resistant packaging materials. Results of similar tests of other chemicals will be published as the tests are completed. The study is part of a broad program of continuing research designed to reduce marketing costs and expand the market for farm products.

The performance data on the chemicals included in this report were assembled and tabulated by R. H. Guy, Stored-Product Insects Laboratory, Savannah, Ga.

Several past and present members of the staff of the Stored-Product Insects Laboratory, Savannah, Ga., have participated in this evaluation program. The program since its inception has been under the general direction of Hamilton Laudani, formerly Savannah Station leader and now assistant head, Stored-Product Insects Section, Agricultural Marketing Service, Beltsville, Md. F. O. Marzke, W. J. Patterson, D. F. Davis, H. T. Vanderford, G. W. Angalet, R. W. Lapsley, G. R. Swank, and R. H. Guy were responsible for the laboratory work described. They were assisted by L. L. McDonald, P. G. Mahany, and Charles Metts.

An evaluation program, such as described in this report, could not have been conducted without the chemical synthesis programs of Government and industry laboratories. The majority of the compounds were synthesized by S. I. Gertler and W. F. Barthel of the Pesticide Chemicals Research Laboratories, Entomology Research Division, Agricultural Research Service, Beltsville, Md. R. W. Ihndris verified the nomenclature of the compounds. The Orlando, Fla., laboratory, Insects Affecting Man Section, Agricultural Research Service, rendered valuable assistance by making available samples of compounds found to be effective repellents in their screening program.

SUMMARY

This report presents the results of preliminary laboratory evaluation tests made with 534 experimental compounds to determine their efficacy as repellents against stored-product insects. The studies were conducted at the Savannah, Ga., laboratory as part of a research program on the development of insect-resistant packaging to find additional materials other than pyrethrum, the only chemical approved for package treatment by the Food and Drug Administration at the present time.

N-pentylphthalimide applied at 200 mg. per square foot was the only compound that produced a repellency greater than that of the standard treatment, and 11 additional treatments are considered to produce a repellent action comparable with that produced by the standard.

The laboratory technique used in the evaluation of these experimental compounds and its development were described in detail in a previous report, therefore only a brief account of the method is given in this report. The insects used in the repellency tests were 3- to 28-day-old adults from mixed cultures containing the confused flour beetle, Tribolium confusum Duv. and the red flour beetle, T. castaneum (Hbst.). Previous work has shown that these two species behave identically within the limits of these tests. A standard of paper treated with synergized pyrethrum at the rate of 10 mg. of pyrethrum and 100 mg. of piperonyl butoxide per square foot was used in all tests for comparative purposes.

LABORATORY EVALUATION OF PROMISING COMPOUNDS AS REPELLENTS TO FLOUR BEETLES, TRIBOLIUM SPP.

Stored-Product Insects Laboratory
Savannah, Georgia¹

INTRODUCTION

The Stored-Product Insects Laboratory, Savannah, Ga., for the past 7 years has been engaged in research on the development of insect-resistant packaging. During this time a sound appreciation has been developed of the important factors which influence the improvement of the insect resistance of food packaging. These factors were discussed in detail by Laudani and Davis² in a review of the program. One of the factors discussed was the advisability of finding additional materials other than pyrethrum, which at the present time is the only chemical approved for package treatment by the Food and Drug Administration. The supply of pyrethrum in this country is dependent on foreign sources, and the material is very expensive, has a relatively short life, and is difficult to analyze.

A continuous phase of this research project on the development of insect-resistant packaging is the preliminary evaluation of experimental compounds to determine their efficacy as repellents against stored-product insects. The materials to be tested are obtained from various sources, but only those compounds showing some promise as repellents in previous tests are included in the tests conducted at Savannah. Primarily, these sources consist of the synthesis program of the Beltsville, Md., laboratory of the Pesticide Chemicals Research Laboratories, Agricultural Research Service; the Orlando, Fla., laboratory of the Insects Affecting Man Section, Agricultural Research Service; and various companies in the pesticide chemicals industry.

This report presents the results of these laboratory evaluation tests from the time of their initiation until the present. During this period a total of 534 compounds has been tested.

The laboratory technique used in the evaluation of these experimental compounds and its development were described in detail by Laudani and others.³ A brief account of the method is given herein, but the reader is urged to examine the indicated reference for a better understanding of the technique.

PROCEDURE

The insects used in the repellency tests were 3- to 28-day-old adults from mixed cultures containing the confused flour beetle, Tribolium confusum Duval, and the red flour beetle, T. castaneum (Herbst). Previous work has shown that these two species behave identically within the limits of these tests. The culture medium used for rearing the test insects consisted of 50 percent of flour, 45 percent of corn meal, and 5 percent of brewer's yeast. The rearing was conducted in a room in which the temperature was maintained at $80^{\circ} \pm 2^{\circ}$ F. and the relative humidity at 60 ± 5 percent.

The repellent compounds were applied in acetone solutions. They were prepared by adding to a known volume of solvent the required amount of the compound to give the deposit desired when 3 ml. of the solution was applied to a 4- by 16-inch strip of test paper. The material was applied with an automatic blade applicator (fig. 1). After treatment, the papers were labeled and allowed to dry for 4 days before they were used in the tests.

¹ This is one of the field stations of the Stored-Product Insects Section, Biological Sciences Branch, Marketing Research Division, Agricultural Marketing Service, U. S. Department of Agriculture.

N-26961

Figure 1. --Application of acetone solutions of experimental chemicals to kraft paper with an automatic blade applicator.

The repellency-test sheets consisted of a strip of treated paper and a strip of untreated paper joined edge-to-edge with cellulose tape on the bottom side. The joined strips were then cut into two sections, each being 8 inches long and approximately 7 inches wide. The two sections were placed on a table so that the treated half of one was turned to the right and the treated half of the other turned to the left, to counteract any undetermined external influences on the distribution of the insects (fig. 2). Two glass cylinders were placed on each of the two sections of paper. The cylinders were positioned so that the seam joining the treated and untreated papers formed the diameter of the test arena, thus providing equal areas of treated and untreated paper.

The glass cylinders used to confine the test insects on the repellency arenas were oil-cup glasses which measured 3 inches in height and 3 inches in outside diameter, and were made of 3/16-inch-thick glass. Each end of these cylinders was machined smooth; and therefore, either end could be placed on the paper to produce an insect-tight union. These oil-cup glasses had sufficient weight to press down folds that were present in some of the treated papers.

Each new series of repellency tests was begun on Monday morning and continued through 5 days, with 10 adult flour beetles in each glass cylinder. Counts were made twice daily to determine the number of insects on the treated and untreated paper in each arena.

BN-7330

Figure 2.--Laboratory technique for determining the repellency to flour beetle adults of chemicals applied to kraft paper. Note test arenas composed half of treated paper and half of untreated paper.

Therefore, the data obtained amount to 10 readings of 4 replications or 400 individual insect positions for each treatment. Inactive or dead insects were disregarded, and were replaced with active ones. The average was determined for each reading of the 4 cylinders, and at the end of the fifth day the average for the daily readings was determined. This average was then converted to the percentages of the insects which were counted on the two surfaces.

Four aging tests were conducted with the same papers to determine the persistency of the repellent action produced by the various treatments. These tests were conducted according to the procedure used in the initial tests and the results were tabulated and presented in the same manner. Aging tests were conducted for 5-day periods beginning 2 weeks, 1, 2, and 3 months following the applications.

Untreated checks were included in each series of repellency tests. The preparation of and the techniques used with the untreated check sheets were identical to those described above except that neither half of the paper was treated. On the untreated checks, counts were made of the number of insects on each side of the seam. The reliability of the test was dependent on obtaining a 50-50 normal distribution on the two halves of the untreated check. The readings for the untreated check arenas were tabulated as 50 percent plus or minus the deviations from the 50-50 distribution.

A standard was used in all tests for comparative purposes. This standard consisted of paper treated with synergized pyrethrum at the rate of 10 mg. of pyrethrum and 100 mg. of piperonyl butoxide per square foot.

EVALUATION OF RESULTS

The percentage value shown in the appendix for each of the treatments represents the average number of test insects counted on the untreated half of the repellency arena during the initial 5-day period and the 4 aging-test periods. The figures for the untreated portion of the arena were selected for presentation in order that high values would be associated with greater repellency. These figures have been converted to express percent repellency or attractancy by doubling the difference between the percentage of insects counted on the untreated half and the 50-percent expected distribution. The positive figures (+) express repellency and the negative figures (-) attractancy. The "percent repellency" values are expressed on a scale consisting of the following five categories: Class 0, all negative values (no repellency); Class I, from 0.1 to 20 percent repellency; Class II, from 20.1 to 40 percent repellency; Class III, from 40.1 to 60 percent repellency; Class IV, from 60.1 to 80 percent repellency; and Class V, from 80.1 to 100 percent repellency.

Many of the 534 compounds were evaluated at several rates of application. Each application was considered an entity and for each the percent repellency value and classification were designated. Based on this method of treating the results of these evaluation tests, the number of treatments assigned to each of the repellency categories was:

Class 0	193 treatments
Class I	432 treatments
Class II	236 treatments
Class III	54 treatments
Class IV	11 treatments
Class V	1 treatment

The one treatment designated in the Class V category was N-pentylphthalimide applied at 200 mg./sq. ft. The results obtained with this compound were described by Swank and others.⁴ Of all compounds tested, this is the only one which has produced a repellency greater than that of the standard used for comparison.

The 11 treatments designated in the Class IV category were (in order of decreasing effectiveness):

<u>Compound</u>	<u>Rate of application</u> <u>Mg./sq. ft.</u>
1. Phthalimide, <u>N</u> -pentyl-	100
2. Ether, 2,4-dinitrophenyl phenyl	100
3. Phenol, 2,3,5,6-tetrachloro-	200
4. (2 above)	50
5. (2 above)	200
6. 1-Piperidineacetic acid, cyclohexyl ester	200
7. 1,4-Cyclohexanedicarboxylic acid, diallyl ester	200
8. Glutamic acid, <u>N</u> , <u>N</u> -diisopropyl-, propyl ester	100
9. (2 above)	25
10. (6 above)	100
11. Benzamide, <u>m</u> -chloro- <u>N</u> , <u>N</u> -diethyl-	200

As the standard used for comparison always is classified in the Class IV category according to the test method used, all of the compounds listed above are considered to produce a repellent action comparable with that produced by the standard.

⁴ Swank, G. R., Davis, D. F., and Gertler, S. I., N-pentylphthalimide as a repellent for possible use on insect-resistant packaging. Jour. Econ. Ent. 50(4):515-516. 1957.

Recently there has been considerable interest in insect attractants. The test technique as described in this report permits evaluation of attractancy of the chemicals as well as the repellency. In the tabulation of results, negative percentage values indicate that the flour beetle adults were attracted to the treated surface, the higher negative value indicating greater attractancy. Based on this interpretation of the results, the following compounds were designated the most effective attractants (in order of decreasing effectiveness):

1. Phthalic acid, diisopropyl ester
2. 5-m-Dioxanol, 2-(1-ethylpropyl)- and 1,3-Dioxolane-4-methanol, 2-(1-ethylpropyl)-
3. Naph[2,3-c]acridine-5,8,14-(13)trione, 11-chloromethyl-10-methyl-, 1,1,3-trimethylisothiuronium salt
4. Benzyl alcohol, alpha-(trichloromethyl)-
5. Propionic acid, 3-(2-ethoxyethoxy)-, 2-ethoxyethyl ester
6. Valerophenone, 4-methoxy-
7. Lactic acid, tetrahydrofurfuryl ester, ethyl carbonate
8. 5-m-Dioxanol, 2-(1-ethylpentyl)-
9. Acetic acid, cyano-, 3-methylcyclohexyl ester
10. Chrysanthemumamide, N-3-(isopropylaminopropyl)-

The Department of Agriculture intends to publish progressive supplementary reports of the results of the program on preliminary evaluation of the repellency of experimental chemical compounds to stored-product insects.
