PROGRAM

33rd ANNUAL AGRICULTURAL OUTLOOK CONFERENCE

Washington, D. C.

Nov. ~~December~~ 28 ^{Dec} ~~January~~ 1, 1955

PRODUCTION CONSIDERATIONS
 IN THE 1956 FRUIT AND TREE NUT OUTLOOK

Prepared for the 33rd National Outlook Conference,
 Nov. 28 - Dec. 1, 1955, by the Fruit and Vegetable
 Statistics Branch, Agricultural Estimates Division,

U.S. Agricultural Marketing Service, U. S. D. A.

PRODUCTION CONSIDERATIONS
IN THE 1956 OUTLOOK FOR
FRUITS AND TREE NUTS

The level of total fruit production in the United States has increased about 17 percent during the past 15 years, while population during this period has increased about 24 percent. This means that per capita production of fruits has been declining for several years despite higher consumer purchasing power.

The total production of citrus fruits has increased 70 percent since 1939, despite severe freeze damage in several producing areas during this period. This upward trend in citrus production is expected to continue for several years but at a slower rate of increase. Florida continues to expand in bearing capacity, both from new plantings and increasing size of trees. The trend in California oranges and grapefruit is moderately downward and for lemons, about level. Texas citrus trees of all kinds were nearly wiped out in February 1951. The level of production was reduced from about 30 million boxes to less than 1 million but has been reviving since the freeze, reaching 4 million boxes in 1954-55. Texas production should continue to increase for several years. Arizona citrus production probably will not change materially for at least a few years.

Fresh sales of citrus fruits increased steadily from about the turn of the century until the period from 1943 to 1946. Since 1946, total fresh sales of citrus have declined moderately and are now at about the same level as in 1939. Processing of citrus fruits, on the other hand, has continued to increase steadily and the level is now about four times that of 1939. Until about 10 years ago, canned single strength juice was the principal product, but in recent years frozen concentrated orange juice has become the most important citrus product. Frozen concentrated orange juice now accounts for more than a third of all oranges produced in the country and about two-thirds of all oranges processed.

The level of noncitrus fruit production is about the same as it was 15 years ago. Total noncitrus fruits probably will remain at approximately this level for the next few years. Lower levels since 1939 for apples, peaches, prunes, and figs have been offset by increases in pears, grapes, cherries, and cranberries. Apricots, plums, strawberries, and olives are at about the same level of production as 15 years ago. Fresh sales of noncitrus fruits have declined moderately since 1939 while total processing increased about the same amount. Increases in canning and freezing during

this period were about offset by a decline in dried fruits. The production of other processed products--principally vinegar, wine, and jelly--is at about the same level as in 1939.

Total tree-nut production (almonds, walnuts, filberts, and pecans) has increased about 40 percent during the past 15 years, with increases in each of the 4 major kinds. The trend should continue upward for almonds and walnuts for a few years but probably has leveled off for filberts and pecans.

Oranges: The trend in orange production has been upward for 50 years and will probably continue upward for several years but at a slower rate of increase. Production of oranges in the United States is now in greater volume than for any other fruit crop. More than half of the United States production is processed. The production of frozen concentrated orange juice is probably the outstanding development in the United States fruit industry in recent years. The packing of this product on a commercial scale started only about 10 years ago. However, it increased so rapidly that in the past two seasons more than a third of the United States orange crop was used for frozen concentrate. Nearly all of this product has been made in Florida.

Production in Florida for most kinds of oranges continues sharply upward. In California, the production trend has turned moderately downward for both navels and Valencias. California Valencias are essentially the only fresh oranges available during the summer and early fall. This has been a great advantage to California in marketing her Valencia crop. This advantage has been sharply reduced by the competition of frozen orange concentrate from Florida. The pressure of this competition will probably increase as Florida production increases. Many California citrus groves are giving way to the expanding cities and towns, especially in Southern California. Arizona orange production probably will not change materially in the next few years. The Texas production will be relatively small for a few years because of severe freeze damage in 1949 and 1951.

Grapefruit: The production of grapefruit in the United States increased rapidly from 1939 until 1949 when the upward trend was halted by a freeze in Texas. Another Texas freeze in 1951 killed most of the trees. Texas production is expected to increase in the future. The trend in Florida grapefruit will probably continue moderately upward for several years.

Lemons: The level of lemon production has not changed significantly during the past 15 years. A slight to moderate increase is possible in the next few years, since the increase in population should increase the demand for fresh lemons as well as the new processed products such as frozen lemonade concentrate.

Apples: Apples account for about a third of the noncitrus fruit total and provide almost half the fresh market supplies of domestic noncitrus fruit. The production trend for apples has been moderately downward since 1939, and appears to be leveling off at 15 to 20 percent below the production potential of 1939. Sales of nursery stock are reported to have been large during the past 2 years. The decline in apple production has been accounted for mostly by the removal of low yielding orchards and less desirable varieties. Despite the downtrend in production, processing has been increasing, particularly the canning of applesauce in the East.

The production of apples in New England has increased moderately since 1939, in contrast with moderate to sharp declines for all other important producing areas of the East. New York is down about a fifth and the Appalachian area (Pennsylvania, Maryland, Virginia, West Virginia) is down about a fourth. These areas have probably leveled off in production.

Michigan production has fluctuated between 5 and 12 million bushels since 1939 but production capacity has declined only slightly. This trend is expected to hold about level or increase moderately during the next few years. The total production level for the other Central States is down about a third with considerable variation among the States.

Washington State produced a record crop of $35\frac{1}{2}$ million bushels in 1950. The following four crops were each less than 25 million bushels but the 1955 crop is estimated at 31 million. Production capacity in this State declined moderately between 1939 and 1943 but has been increasing since 1943 and is now about the same as in 1939. This slight upward trend is expected to continue during the next few years.

California apple production increased from 1939 to 1947 when a record crop of 11 million bushels was produced. The trend has leveled off moderately below the peak of 1947 and is expected to hold about steady for a few years. Each of the other Western States shows a decline since 1939 and a slight to moderate decline can be expected for the next few years.

Peaches: Peaches are exceeded in importance only by apples and grapes among noncitrus fruits. Fresh sales of peaches amount to about half of production and are second only to fresh apple sales in tonnage. Production increased sharply from 1939 until 1946 and has since declined to a level slightly below that of 1939. In the spring of 1955, a disastrous freeze in the Southern States practically wiped out the 1955 peach crop in those States and killed or damaged a great many peach trees. The production capacity in these States will be reduced for at least 2 or 3 years.

The potential level of production in California, where about one-half of the United States total peaches are grown, has increased moderately during the past 10 years. About two-thirds of the peaches produced in California have been clingstones used principally for canning. In order to hold production of clingstones within the limits of market requirements, California growers have put into operation a "green drop" program in recent years of large production. This program, which is operated as part of a marketing agreement, has resulted in the elimination of about 15 percent of production by stripping the green fruit from the trees early in the season.

The production level in the important Western States of Colorado, Washington, and Oregon increased between 1939 and 1946 but has not changed significantly during the past 10 years. No important changes are expected in these States during the coming few years except some possible expansion in the Grand Coulee Project of Washington.

Production trends in nearly all areas of the Northeastern and North Central States have been moderately downward except in New Jersey, which has shown a moderate increase.

The Southeastern and South Central States have been decreasing in production levels at rates from moderate to rapid. The 1955 freeze in these States will no doubt accelerate the downtrend--at least temporarily.

Pears: Pear production increased moderately between 1939 and 1947 and has since declined to about the same level as in 1939. The three Pacific Coast States produce more than four-fifths of the Nation's pears and the proportion is increasing. Little change is expected during the next few years in overall pear production. The pear crops in California and Oregon have increased about 50 percent since 1939, while the Washington crop has not changed significantly. The increases in California and Oregon have been offset by decreases in nearly all Eastern and Central States. Fire blight has been a serious threat to pear trees for many years in nearly all areas of the country. The Western States have been able to keep the blight under control but damage in the Eastern and Central States has been severe. Some of the new treatments, especially antibiotics, show promise of controlling blight.

Grapes: The level of grape production in the United States increased about a fourth between 1939 and 1951. Since 1951, the trend apparently has turned downward. California continues to produce about nine-tenths of the United States total grapes. All three classes of California grapes (wine, table, and raisin) show about the same trend pattern since 1939--an increase between 1939 and 1951 and a moderate decline since 1951.

Grape production in Washington has increased steadily for more than 20 years and is now exceeded only by California and New York. The present level is more than four times as large as it was 15 years ago. This upward trend will probably continue for a few years. Production in the Great Lakes States varies widely from year to year from the effects of weather but the trend has been upward since 1939.

Cherries: The trend in production of sweet cherries was sharply upward until 1949 and has not changed significantly since. Little change is expected in the near future.

The production potential for sour cherries has increased steadily in the past 16 years and is now about 50 percent higher than in 1939. Actual production has fluctuated widely from year to year because of damage from freezes, frosts, and storms. The biggest crop to date was in 1951 when about 158,000 tons were harvested, including 8,700 tons which were not utilized because of low prices. In 1952, 1953, and 1954, production ranged from 108,000 to 132,000 tons but in 1955 again reached the 150,000-ton mark.

Production is expected to trend moderately upward for several years because of extensive recent plantings in Michigan and New York.

Plums: Plums are estimated only for California and Michigan. California produces more than nine-tenths of the total. The production level is moderately higher than in 1939. Very little change is expected in the near future.

Prunes: Production has declined about a fourth since 1939 but is expected to change very little in the next few years. Sharp drops occurred in Washington, Oregon, and California. The level in Idaho changed very little but Idaho accounts for only about 5 percent of the total production. Practically all of the California prunes are dried while most of the prunes in Washington, Oregon, and Idaho are sold fresh or canned.

Apricots: The level of apricot production has declined about a fourth since 1939. This decline is expected to continue for some time but at a slower rate. California produces about nine-tenths of the United States crop. From a fourth to a third of the crop is dried--all in California.

Cranberries: Cranberry production has trended upward since 1939. This trend probably will continue for a few years. Processing is the most important factor in the increase of cranberry production. Prior to 1934, processing was not important, but this utilization has since

expanded rapidly and now accounts for more than half of the production. The marketing season is extended throughout the year by the canned pack of cranberry products. Massachusetts has consistently produced more than half of the United States crop but the proportion of production in Massachusetts is decreasing as Wisconsin, Washington, and Oregon become more important producers. New Jersey holds at about the same level. Wisconsin has more than doubled in production since 1939 while Washington and Oregon crops are about 5 times as large as in 1939.

1/ Citrus fruit total includes oranges, tangerines, grapefruit, lemons, limes. The season for citrus fruits begins with the bloom of the year shown and ends with the completion of harvest the following year.

2/ Noncitrus fruit total includes apples (commercial) peaches, pears, grapes, cherries, plums, prunes, apricots, figs, olives, avocados, cranberries, strawberries.

3/ Tree nut total includes almonds, walnuts, filberts, pecans.

4/ Per capita production based on total population July 1 for years 1939-40, population eating out of civilian supplies, 1941-54. Estimates from data of Federal agencies with adjustments for under-enumeration.
