INTRODUCTION

The Division of Farm Management and Agricultural Economics of the University of Minnesota, the Bureau of Agricultural Economics of the United States Department of Agriculture and from 18 to 25 farmers have been cooperating over a three year period in studying the comparative costs and returns from the principal crops grown in the vicinity of Crookston, Polk County, Minnesota. Polk County is located in the Red River Valley in the northwestern part of the state. The farms in this section are typically small-grain farms averaging over a half section in size. The soil is black clay loam and the land is all level and tillable except along the streams. Wheat, flax, potatoes and sugar beets are the principal cash crops. Oats and barley are produced chiefly for feeding on the farm, altho any surplus may be marketed. Alfalfa and wild hay provide most of the roughage fed to the livestock.

This preliminary report presents data on comparative costs and returns for the nine principal crops grown on twenty-three cooperating farms for the crop season of 1928. A summary of the average cost and returns for each of these crops for 1926, 1927, 1928 and the three year average is also presented. In preparing these tables in so far as possible the factors of production have been charged at local market prices. Man labor has been charged at 25 cents per hour and tractor work at \$.90, \$1.20 and \$1.50 per hour respectively for a two, three and four plow tractor. Horse labor was charged at 8½ cents per hour in 1926, 12 cents in 1927 and 10 cents in 1928. Manure was charged to the crops on a three year basis at 50 cents per ton plus the cost of hauling and spreading it on the field. Summer fallowing charges, consisting of a charge for the land and the labor of fallowing, was distributed over a three year period. The summer fallowing charge was not calculated for 1926 as the necessary data from previous years were not available. Machinery and land were charged at flat rates. The December 1 farm price in the vicinity of Crookston was used in determining the returns from each crop.

The statements on wheat, oats, barley and flax include the labor through the first disposition of the crop. If the crop was hauled directly from the threshing machine to market that marketing labor has been included.

Labor for marketing after the grain had been stored on the farm was not included. The cost of alfalfa and wild hay was computed only through putting it in the stack or mow. The hours of labor on sugar beets do not contain any hours for the contract labor, but the cost of contract labor was included in the labor charge. The marketing charge on sugar beets consists of the man and horse labor utilized in marketing the beets. This labor is not included in either the hours of labor or the total labor cost. Potato picking has been charged at 5 cents per bushel and all hours of picking excluded. The potato statement covers only the cost on the farm and does not include any marketing labor. No credit has been allowed for either wheat, oats, barley or flax straw nor for sugar beet tops.

The returns from crops are expressed in four different ways, namely, gain or loss, net return for land, per cent earned on land and return per hour of man labor. The gain or loss shows what is left after subtracting all the specified charges. A minus figure indicates a loss, or the failure of the value of the crop to equal the costs. The net returns for land indicates what remains to pay for the use of the land after all the other factors have been paid. The per cent earned on land is the net return for land divided by the value of the land. Wild hay land was valued at \$40.00 per acre and all other crop land at \$80.00. If wheat showed 15 per cent earned on land it meant that the wheat crop paid the prices charged for all the other factors and still earned 15 per cent on an \$80.00 investment in the land. The return per man hour expresses the returns in a fourth way. A return of \$.65 per hour on wheat means that the wheat crop could have paid 65 cents for every hour of man labor it used and still allowed the prices charged for the other factors of production.

In studying the data presented it should be kept in mind that sugar beets and potatoes are generally given the cleanest and best ground. Flax is often planted on new breaking or on inferior land not regularly cropped, which is not always well prepared. On the other hand sugar beets have been charged the full value of the commercial fertilizer applied. The following crops received some benefit from the unused fertilizer left in the soil as well as from the thorough tillage and weed eradication methods practiced with the beet crop.

The summary for the three year period indicates that there is relatively little variation between years in either the average amount of labor used or in the cost per acre. However, the cost per bushel or ton and particularly the December 1 price display wider variations. When the return per man hour is considered, it is seen that wheat, barley, sugar beets, alfalfa and wild hay have all returned something for the labor every year. As an average for the three year period all of the nine crops except corn silage and oats have yielded a return of over 25 cents per hour.

The tables presenting each individual's costs and returns show a wide range between farms in the returns from any one crop. Both high and low returns were realized on all the crops except potatoes and corn silage. The potato data in 1928 have been computed only to the cost per bushel since the abnormally low price would have resulted in a loss in every case.

Because of the wide fluctuation in prices from year to year returns from potatoes vary widely. It is typical "feast and famine" crop. A statement of returns for an individual year is likely to be misleading unless presented in connection with data for a period of years. It will be noticed that the tables also show a wide variation in yields and that the variations in returns tend to correspond with these variations in yield. This association of high yields and high returns is illustrated by the following table which shows the relation of yield to cost and returns for barley.

Relation of Yield per Acre to Cost and Returns for Barley
Crockston, Minnesota - 1928

Yield per Acre	No. of farms	Average yield	Net cost per acre	Cost per bu.	Gain per A.	Return per man hour
16 to 24 bu.	6	20	\$12.33	\$.62	-\$3.13	-.30
25 to 32 "	6	28	12.89	.46	.13	.27
33 to 40 "	6	36	14.95	.42	1.69	.44
Over 40 "	3	49	14.26	.29	8.58	1.34

As the yield increased the cost per bushel decreased in spite of a greater cost per acre. As a result of the double effect of having more bushels and a lower cost per bushel, the gain per acre and the return per man hour increased quite rapidly. A similar relation between yields, costs and returns existed in case of all the crops studied.

Yield per acre is only one of the causes of variations in returns. Costs and prices also exert an influence but space will not permit an analysis of these other factors. Each individual comparing his results with those of the other cooperators and with the average should find ways of increasing the returns from his crop enterprises.
