Selected Characteristics of North Dakota Farms

by

Ronald D. Krenz 1/

Introduction

This report supplements an earlier report entitled "Farm Characteristics For North Dakota by Economic Areas." 2/ The earlier report was based on data obtained in 1960 and 1961 from Agricultural Stabilization and Conservation Service (ASCS) records on 3,580 farms in 32 counties in North Dakota. In 1963, the following additional data were obtained for this same sample of farms:

1. Acreage of feed grains
 - a. 1959-60 average acreage of barley
 - b. 1959-60 average acreage of corn
2. Normal conserving acreage
 - a. 1959-60 average acreage of hay and pasture on cropland
 - b. 1959-60 average acreage of summerfallow

This additional information allows the estimation of feed-grain base acreages and normal-conserving base acreages for farms in each area. These items are important aspects of both present and future wheat and feed grain programs.

These data are reported herein for farms cross-classified by acreage of cropland and noncropland in each of several areas of the State. This report presents selected characteristics of the average farm in each group. This classification should better describe North Dakota farms and should be useful in continuing farm economic research.

1/ Agricultural Economist, Farm Production Economics Division, Economic Research Service, U. S. Department of Agriculture, stationed at North Dakota Agricultural Experiment Station, Fargo, N. Dak.

2/ Ullrich, E. O., Jr., and Loftsgard, L. D., Agr. Econ. Rpt. No. 23, North Dakota State University, Fargo, June 1962.

Areas of the State

The previous report presented characteristics of farms classified by size of farm and acreage of cropland within each of the 7 economic areas of the state. In this report, the state is divided into 10 soil-climatic areas whose boundaries do not necessarily follow county lines. Data on farm characteristics are presented for 9 of the 10 areas. Following is a list of the areas and their general location:

- Area A -- South and west of the Missouri River
- Area B -- Northwest
- Area C -- South-central
- Area D -- North-central plains
- Area E -- East-central plains
- Area F -- Southeastern plains
- Area G -- Lighter soils in the northern Red River Valley
- Area H -- Heavier soils in Red River Valley
- Area I -- Lighter soils in southern Red River Valley
- Area J -- Sand hills along the Sheyenne River

Only 6 sample farms were located in the sand hills area (Area J), and hence no description of farms is presented for that area. The various areas and the number of sample farms in each area are shown in Figure 1.

Classification of Farms

Selected characteristics of the average farm in each area are given in Table 1. The characteristics of the average farm in each area are ranked by areas in Table 2.

In each area, the sample farms are cross-classified into groups on the basis of the acreage of cropland and noncropland. This procedure results in 5 to 12 groups of farm types in each area. However a significant amount of variation still is found within each of the groups. The variation in acreage of cropland and noncropland on farms is the rule rather than the exception throughout the state. However, this classification provides a better description of farms in North Dakota than does a state or area average.

The estimates presented in tables 3 to 11 are averages of these groups. The range in amount of cropland and noncropland of the sample farms in each group is given in the table headings. These groupings are not the same in all areas since they are made on the basis of the actual distribution of the sample farms in each area.

In each area, a small number of sample farms are not included in any cropland group because they are unlike farms in any group shown. Most of these other farms are the very small and the very large farms. All farms are included in determining the area average.

Also included are estimates of the actual number of farms in each category in 1960. The number of farms reported in the 1959 Census of Agriculture by counties and by acreage of cropland was used as the basis for these estimates.

Normal-conserving base acres per farm-----	B, A, D, E, G, H, C, F, I
Normal-conserving base acres as percentage of cropland-----	B, A, D, E, G, C, H, F, I

Summary of Farm Characteristics

Based on area averages, the largest farms in North Dakota are south and west of the Missouri River (Area A). Farms in this area also have the largest percentage of noncropland, 53.9 percent.

Farms with the largest acreages of cropland, wheat allotments and normal-conserving base acreages, are found in the northwest (Area B). Many farmers in Area B follow a wheat-fallow rotation on most of their cropland acreages. On an average basis, in North Dakota, wheat allotments as a percentage of cropland are highest in the west and north, decreasing to the east and south.

The farms in south-central North Dakota (Area C) have small acreages of cropland (second lowest in the state) and a high percentage of noncropland (second highest in the state).

The smallest average size of farm is in the southern Red River Valley (Area I). Farms in this area also have the smallest acreage of cropland. Wheat allotments and normal-conserving base acreages as a percentage of cropland are the lowest in the state. Farms in this area have the largest corn allotments.

In the northern counties, the bulk of the feed-grain base acreages is planted to barley while in the southern counties, especially in the southeast, more acreage is devoted to corn.

The farms with the largest percentages of cropland are in the heavier soil areas of the Red River Valley (Area H). These farms also have the largest acreages included in the "all other crops" item, such as sugarbeets, potatoes, flax, soybeans and oats. Since the delineated areas do not follow county lines, the first adjustment was to divide the number of farms in a county between two or more areas. Since the census does not classify farms by acreage of noncropland, a

second adjustment was made, using the proportion of farms in the ASCS sample to obtain estimates of farms classified by noncropland. Some final adjustments were made to insure that the numbers of farms times the acreages check with the total land on farms in each area.

In tables 3 to 11, the wheat allotment estimates represent the 1959 allotments. The feed-grain base acreages are the ASCS established feed-grain bases for the years 1959 and 1960. The estimates of normal-conserving base acreages also apply to the years 1959-60 and follow the ASCS definitions of conserving acres. Hay and pasture includes only grasses and legumes and not small grains harvested for hay. The estimate for summerfallow includes some acreage designated as "idle land" on ASCS records.
