Rural Development Research in North Dakota

Acknowledgements

The authors are indebted to vegetable growers and numerous businesses and governmental agencies who have provided support and data for this study.

Special recognition is given for financial support provided by Cooperative State Research Service (CSRS) of the U.S. Department of Agriculture, under project number 8802822, the Institute for Business and Industry Development (IBID) at North Dakota State University, the North Dakota Agricultural Products Utilization Commission, and the North Dakota Agricultural Experiment Station.

The authors would like to thank those who provided reviews of this manuscript: Drs. George Flaskerud, Bill Wilson, Professor Tim Petry, Mr. Dale Zetocha, and Ms. Charlene Lucken. Appreciation is given to Marna Unterseher for typing draft copies and the final copy. The authors accept sole responsibility for any omissions or errors.

Highlights

A yield of 300 masters (50-lb. bag) per acre and a price between \$6 and \$7 per master would be needed for a commercial-sized onion producer to cover all costs in North Dakota. When transportation costs from North Dakota and competing production areas were compared, North Dakota primarily had transportation advantages in local but not regional markets.

In an earlier study on the "Economic Feasibility of Vegetable Production, Marketing, and Processing in the Red River Valley of North Dakota," Dufner et al. found that both onions and carrots have production and marketing potential in North Dakota.

This paper is a summary of the economic feasibility of onion production marketing, and processing in North Dakota. Case study data from Dufner et al. and an expanded model developed from a study by the Agricultural Economics Department at Michigan State University were used to evaluate the economic feasibility of commercial onion production.

ECONOMIC FEASIBILITY OF ONION PRODUCTION, MARKETING, AND PROCESSING IN NORTH DAKOTA

Joel T. Golz, Theresa K. Golz, Delmer L. Helgeson, and Hugh J. Dufner

Introduction

Onions were a significant crop in the Fargo-Moorhead area during the 1940s and 1950s when farmers planted over 1700 acres.¹ The major Fargo-Moorhead onion growers gradually ceased onion production due to price instability and competition from western growers who popularized the mild Spanish onion types. Onions also were raised in the Grand Forks area and farther north. One major onion grower remains in the Fargo-Moorhead area and annually produces about 50 acres. A limited number of farmers in the northern Red River Valley raise smaller amounts.

Although local market demand for onions is strong, it is not strong enough to support a substantial expansion in acreage. Regional marketing may be feasible, and the potential appears quite good for onion production and marketing because the product keeps well, can be harvested mechanically, and existing potato storage facilities can be adapted for storage. Production of direct-seeded onions can be accomplished by planting early in the spring, especially with fast-maturing types. Direct seeding of Spanish onions is risky due to their long growing period and the difficulty of curing them under wet harvest conditions. Transplanting greenhouse or southern grown Spanish onions is feasible for small acreages, because producers can enter the market at least one month earlier than with direct seeded onions. Fast maturing winter storage varieties are recommended for large acreages rather than transplants which are too expensive. Weeds, a serious problem for onions, can be controlled chemically.

Small acreages of onions can be hand harvested into burlap sacks and allowed to dry in the field. This is appropriate for large Spanish onions that mechanical harvesters can bruise. Large commercial acreages require specialized equipment, including a rod weeder for uprooting the bulbs, a windrower or an adapted two-row potato digger to gather the bulbs after they are dry, and an onion harvester to lift them into trucks after curing.

Onions (depending on variety) can be stored for up to eight months at 32°F and low humidity. A continual movement of air around and through them is important to keep them dry so they don't sprout.

Onion Production Potential for North Dakota

U.S. onion production has gradually increased over the past 10 years from 35.9 million cwt. in 1978 to 45 million cwt. in 1987 (Figure 1). Increased yields rather than increased acreage caused the additional production. The 1978-82 average yield was 309 cwt. per acre compared to 369 cwt. for the 1983-87 average.

Two factors influence the growing demand for onions, population growth and increased per capita consumption of onions. From 1978 to 1987, U.S. resident population increased from 222 million to 243 million, a 10 percent increase. Per-capita consumption during the same period increased from 13.7 pounds in 1978 to 16.3 pounds in 1987, a 19 percent increase (Table 1).

Seasonal Production

The United States Department of Agriculture classifies onion production into four categories: spring, summer non-storage, summer storage, and summer California. Although onion production has increased over the past 10 years, the market share among USDA categories has remained constant. Spring production accounts for 16 percent, summer non-storage onions for 7.8 percent, summer storage onions for 54 percent, and summer California onions for 22 percent of total production. Comparing 1978-82 averages with 1983-87 averages indicates spring and summer California production have remained constant while summer non-storage onion production has declined and summer storage onion production has increased (Table 2).

TABLE 2. U.S. SEASONAL MARKET SHARE OF ONIONS, 1978-82 and 1983-87

Category	1978-1982	1983-1987
	-----percent-----	
Spring	16.27	15.99
Summer - non-storage	8.62	7.76
- storage	52.81	53.98
- California	22.30	22.27

SOURCE: Adapted from Vegetables, Agricultural Statistics Board, USDA, 1978-1987.

Unlike seasonal production groups where market share is constant, individual state's market shares have distinctive trends. California's share of spring onions is growing at the expense of Arizona and Texas. The market share of Texas' grown summer onions also has decreased. Colorado, Idaho, Oregon, and Washington have increased their market share of summer storage onions. The primary loser of market share was New York, and Michigan to a lesser extent. Minnesota, Ohio, Utah, and Wisconsin each decreased slightly in market share (Table 3).

SOURCE: USDA, Vegetables, Annual Summaries, 1978-1988

Six states produced over 80 percent of U.S. onions from 1983 to 1987. California 28.99 percent, Oregon 14.76 percent, Texas 10.75 percent, Colorado 10.52 percent, Idaho 7.82 percent, and New York 7.75 percent.

Foreign Trade

The U.S. was a net exporter of onions before 1982. In five of the six following years the U.S. was a net importer (Table 4). Exports marginally exceeded imports in 1984, but by 1987 a net trade deficit of 1.75 million cwt existed, approximately 4.3 percent of domestic consumption. Import prices are seasonal and generally are lowest during August and September. Price increases occur monthly and peak in March or April (Figure 2).

Seasonal Shipping

Shipping seasons vary in time and length, depending on the production and climate in the producing states. Arizona, California, and Texas typically do not store crops as refrigeration is too expensive. These states generally plan production to supply fresh products when Northern states cannot meet supply requirements.

Arizona generally ships onions during May and June, New Mexico from June to August, Texas from April to August, and California all year round with most onions shipped from May to August. Colorado, Idaho, Michigan, Oregon, and Washington generally begin shipping in August when harvest begins and continue until March or April as onions are removed from storage (Table 6). Eighty percent of the onions were shipped by truck during 1987, and 13.5 percent by rail, of which 3 percent were by piggyback rail.

Seasonal Pricing and Returns to Storage

Chicago wholesale prices were used to determine seasonality of prices and returns to storage. Major terminal market prices were used because they would reflect the overall U.S. market and would not be subject to local supply and demand factors. The USDA only publishes comprehensive wholesale prices for two major markets, New York and Chicago. Chicago was chosen as the most likely major market for North Dakota produce.

Analysis was limited to a September through March time period because the primary market season for summer storage onions most likely would be produced in North Dakota. Consequently, prices are generally not reported from April to August for

summer storage onions as not enough produce is shipped to establish a price series. Also, the market is generally supplied with spring season production from southern states. The price series used were Idaho-Oregon Yellow Spanish Jumbo onions and Michigan Yellow Medium onions (Tables 7 and 8) for Idaho-Oregon spanish onions. Prices varied from year to year, ranging from \$3.84 for 50 pounds in February 1977 to \$18.50 in March, 1983.

Five-year (1983-1987) and 10-year (1978-1987) indices of monthly onion prices are presented in Figures 2 and 3. Both indices indicate traditional price behavior where prices are lowest during harvest and increase thereafter. Higher prices reward the producer for the additional costs of storing the commodity. Both classes exhibit the same behavior. Prices actually are higher at the beginning of harvest and drop and rise throughout the season.

Prices generally increase throughout the year. Idaho-Oregon onion prices have historically had a higher probability of increasing. Prices from 1978 to 1987 increased eight of 10 years for both three-month and five-month storage periods. Michigan prices increased only four years when storing three months and six years when storing five months. From 1983 to 1987, storage had a positive return every year for Idaho-Oregon onions and four years for Michigan onions. Production in 1984 increased significantly over the previous year, 43.7 versus 38.8 million cwt. and may have prevented prices from rising. Average increases in price from 1978 to 1987 for three and five month storage periods were \$1.62 and \$2.44, respectively, per 50-pound sack of Idaho-Oregon onions. Price increases were greater during the 1983-1987 period, averaging \$2.83 and \$3.87 for three and five month storage periods, respectively (Table 9). Prices were similar for Michigan onions but had not increased to the extent of Idaho-Oregon onions. Price increases averaged \$.42 and \$1.78 for three and five month storage periods from 1983 to 1987, less than half of those for Idaho-Oregon (Table 10).

Market Competitiveness

The market competitiveness of North Dakota depends upon its ability to deliver products to a market at equal or less cost than other suppliers, assuming acceptable quality standards are maintained. Production and shipping costs are the major components in determining final cost.

Published data are not available on production costs for major producing regions in the United States. However, North Dakota's advantage (disadvantage) in shipping cost can be estimated. For the market where North Dakota has a shipping cost advantage, the state can be a competitive supplier providing the differential in production costs does not exceed the shipping cost advantage.

Since primary production of storage onions is located in the West, the potential market for North Dakota production would be markets east or southeast of North Dakota. These would include Minnesota, Wisconsin, Illinois, Indiana, Michigan, Ohio, South Dakota, and North Dakota. Although many of these states also produce onions, they still remain net importers, including North and South Dakota. The exception is Michigan, which is a net exporter of onions. This eight state region is a net importer based on historical production and population estimates. The eight state region accounts for 19.52 percent of U.S. population but only 7.26 percent of U.S. onion production (Table 11). Assuming regional consumption is similar to U.S. consumption, the eight state region produces only 38 percent of what it consumes. In reality this may overstate market potential. Southern states supply the eight states, during late spring and summer, when regional produce is not available. However, since North Dakota is in a deficit region and has a transportation advantage over Western producing states, it could become a market supplier.

Transportation costs were estimated for six markets to determine North Dakota's transportation advantage (disadvantage) relative to other supply points. The markets selected to represent local, regional, and national markets were Fargo, Minneapolis, Sioux Falls, Chicago, New York, and Atlanta. Competing supply regions were Colorado, Oregon-

TABLE 11. REGIONAL MARKET SHARES FOR PRODUCTION OF ONIONS AND POPULATION, 1988

Idaho-Washington, Michigan, and Grand Forks, representing the Red River Valley of North Dakota. Transportation cost advantages (disadvantages) were estimated for the Red River Valley (Tables 12 and 13).

The Red River Valley has a transportation advantage over the Pacific Northwest in all markets, ranging from \$1.75 per 50 pounds to Minneapolis to \$1.33 to Atlanta. The Red River Valley also has a cost advantage over Colorado in all markets. Michigan has a cost advantage in supplying the Atlanta, New York, and Chicago markets.

TABLE 12. ESTIMATED TRANSPORTATION COSTS FOR ONIONS FROM SELECTED ORIGINS TO SELECTED MARKETS, UNITED STATES*, 1989

Market Destinations	Origin			
	Grand Forks	Denver	Pacific Northwest	Michigan
	-----\$/50 lb.-----			
Fargo	.23	1.35	2.09	1.41
Minneapolis	.57	1.42	2.32	1.07

Sioux Falls	.51	1.67	.72

SOURCE: Adapted from Table 12.

Onions are also shipped by rail from the Northwest. A comparison of rail and truck costs for the Northwest indicated rail reduced costs by approximately \$.40 to \$.80 per 50 pounds. This cost reduction reduces the Red River Valley transportation advantages. Rail also incurs additional costs including longer delivery times, potentially higher inventory costs, and greater handling costs. Non-cost considerations include less control over shipping once shipment occurs, potential car scheduling problems, and more restrictive planning horizons.

Case Study

Transplant onions, winter storage onions, and greentop onions will be discussed along with production and cost data for each type of onion crop. The problems and benefits of each type of onion will also be presented.

Transplant Onions

Spanish onion transplants from Georgia were air freighted to Minneapolis and hauled by pickup truck to North Dakota in 1988. The plants were transplanted using a four row transplanter that required six workers, one worker for each row, a tractor driver, and a worker to monitor planting depth.

Onion plants were set 5 1/2 to 6 inches apart in 20-inch rows, for a total of about 50,000 plants per acre. A tractor planting speed of 1/4th to 1/5th mile per hour was required so workers had sufficient time to feed the transplanter. Water from tanks mounted on the tractor was applied as the plants were transplanted. Drought conditions required two or three more waterings so transplants could set roots. The transplanted crop was grown organically with no chemical fertilizers, herbicides, or insecticides. Inoculants were used on onion roots to ensure abundant bacterial life in the soil. Liquid fish emulsion was applied with water for nitrogen.

Planting began in late May and continued through the third week of June, despite the drought. A transplant catch of around 90 percent was obtained with irrigation. The onion transplants were cultivated and hand weeded twice. The seedlings developed large bulbs, most of which were hand harvested into burlap sacks in September.

Harvest began when about 75 percent of the tops had weakened and fallen over. Workers with knives or scissors pulled the entire plant, and cut the bulbs from the tops, allowing the bulbs to fall into pails or baskets before being dumped into burlap sacks and left to dry in the field for up to one week. When the onion leaves rustled in the bags, they were air stacked on rows of pallets in a warehouse allowing ventilation to penetrate the sides and center of each pallet. Fans were used to circulate air around the onions to accelerate the evaporation. The onions were hand graded into five sizes and marketed in 50 pound mesh bags. Packout percentages are shown in Figure 4.

The variable cost of growing transplant onions in 1988 was \$4.81 per 50 pound master, which is about equal to an FOB price of commercial onions grown in Western states (Table 14). The transplants alone cost nearly \$2 per master. Variable harvest and packaging costs were \$3.90 per master, which was double most commercial rates.

Despite high growing costs, which consisted primarily of seedling purchase and transplanting, the transplant onion operation was profitable (Tables 14 and 15). This was largely because fixed costs were low (\$1.70 per master). The onions were shipped early and required only temporary indoor storage.

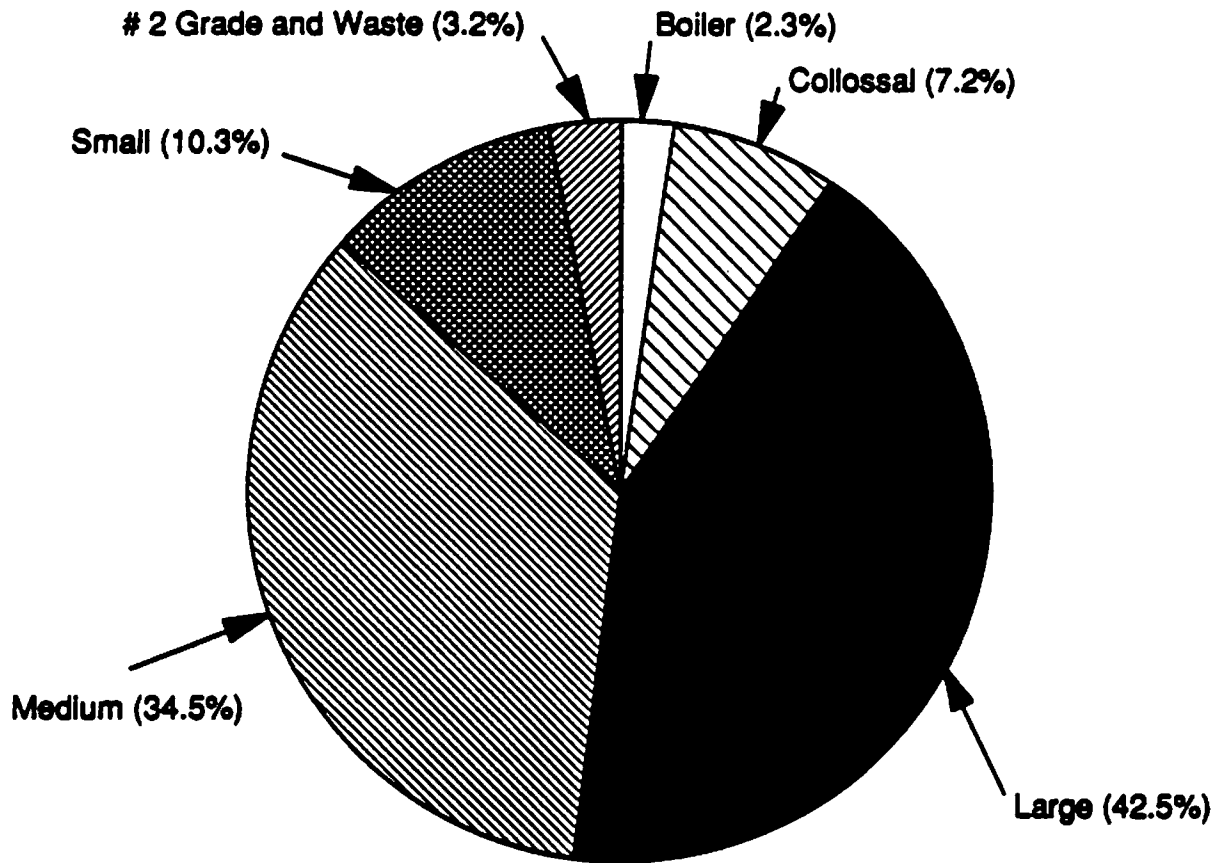

Figure 4. Transplant Yellow Spanish Onion Packout From Case Study in Central Red River Valley, North Dakota, 1988.

Direct Seeded Winter Storage Onions

These onions were planted in 20-inch rows at 3.2 pounds per acre (slightly above the 2.5 pounds per acre recommended for 20 inch row spacing) on 5.3 acres of certified organic land in mid April 1988. The major planting concerns were emergence and weed control in an organic production system.

Seedling emergence was good, resulting in optimal plant density, small bulb size. Weeds were controlled with a beet cultivator and hand weeding within the rows. Migrant labor was not available to pull weeds, and some weeds went to seed before they were pulled. Variable growing costs were \$427 per acre, with 85 percent going for seed and hand weeding.

SOURCE: Case study, approximately 7 acres central Red River Valley, North Dakota, 1988.

Due to high plant density, 1.3 acres of the field were harvested as table onions when the plants reached pencil size. The remaining four acres of onions were hand harvested in early October before a hard frost. Half of the onions were picked by the tops. A small homemade one row onion digger was used to lift the remaining onions. A pull type rod weeder effectively lifted the onions in some parts of the field but skimmed over the soil surface where the ground was packed and hard.

Inadequate moisture resulted in a large percentage of small or "prepack" onions (Figure 5). Variable harvesting, packaging, and marketing costs were exceptionally high due to inadequate harvest equipment and unavailability of grading equipment. Thus, this operation had a net loss (Tables 16 and 17). However, the production of quality winter storage onions in North Dakota is feasible, which area growers have proven.

The organic production of direct seeded onions is troublesome because onions compete poorly against weeds. A heavy weed growth which might occur in normal years, could make hand weeding economically infeasible and result in loss of the crop. Chemical herbicides effectively control weeds for the conventional grower and can be used in North Dakota.

Figure 5. Direct Seeded Storage Onion Packout Percentages From Case Study in Central Red River Valley, North Dakota, 1988.

The major advantage of direct seeded onions over transplants is the considerably lower up-front cost required to establish a seedbed. In an organic system, this advantage may be offset by the higher cost of hand weeding direct seeded onions during their longer life cycle. Since onion seedlings are extremely fragile after emergence, soil cannot be pushed against them during cultivation and drifting soil on windy days can damage or cut them off.

The major advantages of transplant onions over direct seeded onions are:

- a) they permit an early harvest of late maturing varieties (eg. spanish type) which normally implies higher prices.
- b) they facilitate weed control in an organic production system where chemical weed control cannot be used.

The major disadvantages are the increased cost of seedlings over seed and the slow transplanting process.

Greentop Table Onions

A winter storage variety of greentop table onions were planted and harvested from 1.3 acres. Due to high plant density, the onions were harvested before bulbing for sale as table onions.

The greentop table onion operation consisted of hand pulling, gathering onions into baskets, and transferring them to a warehouse where they were spray washed with water. Washed plants were bunched and tied with rubber bands with six to eight plants per bunch. Forty-eight bunches were packed in cartons lined with plastic coated paper for moisture resistance and were marketed to supermarkets in Fargo and Grand Forks biweekly during July. Onion tops were left intact, and no ice was applied due to lack of icing capability.

The major problem was that onion tops quickly lost their fresh appearance, especially if delayed from one delivery day to the next. Onions not sold quickly in supermarkets soon lost their market appeal. Only quality fresh products were acceptable to consumers. Approximately one-third of the hand-harvested onions were discarded due to lack of freshness.

Revenue from the sale of greentop onions (\$1,224) covered most variable costs not fixed costs (Table 18). Fixed costs, when allocated on the basis of equipment usage, were substantial, although the facilities were underutilized during mid-summer when alternative opportunity costs were low.

Fresh greentop onions have market potential for local markets. Local demand for onions in the summer was strong, but varieties that retain their fresh appearance must be selected. The operation is labor intensive, and labor demand is greatest in mid-summer when school-aged youth can work. Irrigation, though not essential, is desirable to ensure a mild onion product.

TABLE 18. TABLE ONION OPERATION COSTS FOR CENTRAL RED RIVER VALLEY CASE STUDY, NORTH DAKOTA, 1988^a

Variable, Fixed and Total Costs	Total Cost	Cost/Acre	Cost/Master
Variable Costs			
Growing Costs			
Seed	138	106	1.15
Cultural operations			
Fall till	7	5	0.05

Expanded Model

The expanded model for this study is based on a study by the Agricultural Economics Department of Michigan State University. Entitled "Costs of Producing Carrots" the study covered fixed and variable costs associated with a commercial sized carrot farm and profitability of carrots under alternative yield and price assumptions.

The same methodology in the Michigan study was used to develop a commercial onion operation for North Dakota. Onions were selected because the case study and a horticultural crop survey indicated North Dakota had favorable conditions for their successful production (Dufner et al. 1990). Although North Dakota does not have a commercial onion operation, this model is available to individuals who want to start an operation specializing in the production of onions.

The following assumptions were made for this model: 1) the farm would consist of 300 acres with 250 acres tillable, 2) 100 acres would be planted to onions, and 3) the remaining 150 acres would be used for grain or other vegetable crops.

Onion Enterprise

Both fixed and variable costs of onions from the Michigan study were used. Some fixed and variable inputs differed between the carrot and onion enterprises. Some inputs were added that specifically pertained to the production of onions. Price and yield used to determine gross receipts are from the case study presented in this paper. Various scenarios are presented to illustrate how losses/returns change with price and yield.

Fixed Costs

Total fixed costs were \$448 per acre. Interest on investment and depreciation were the two largest fixed costs at \$191 and \$142 per acre, respectively. Repairs and maintenance costs were estimated at \$25 per acre. Land was rented and amounted to \$84 per acre (Table 19).

Variable Costs

Variable inputs for the onion enterprise are presented on a per acre basis for both amount used and cost. Variable costs for raising onions amounted to \$2,305.72 per acre. Growing costs accounted for \$1,000 per acre. Major growing costs were herbicide and additives, labor, fertilizer, and machinery repair. Harvesting and marketing costs amounted to \$857. Packing and promotion accounted for almost 80 percent of harvesting and marketing costs (Table 19).

Total Costs and Net Returns

Variable and fixed costs were subtracted from gross receipts to arrive at per acre and per master net returns for onion production (Table 19). The onion operation was profitable at \$7 per master and a yield of 400 masters per acre. This was perceived to be a possible price and yield under the case study conditions. The price received could possibly be higher, depending upon targeted markets (organic) and regional location of markets. Price also can vary if the farmer uses irrigation, because a higher quality product is produced.

TABLE 19. ESTIMATED PER ACRE AND PER BAG COSTS AND RETURNS FOR ONION PRODUCTION CENTRAL RED RIVER VALLEY, NORTH DAKOTA, 1988

Item	Per Acre	Per Master
	-----	-----
		\$
Price	7.00	--
GROSS RECEIPTS (400 bags)	2,800.00	--
<u>Variable Costs</u>		
<u>Growing</u>		
- Seed	97.50	0.24
- Fertilizer	104.60	0.26
- Spray and Additives	361.90	0.90
- Cultural labor	155.85	0.39
- Fuel, oil	85.00	0.32
- Machinery repair	102.00	0.26
- Machine hire	9.00	0.02
- Utilities	18.00	0.05
- Supplies	10.00	0.03
- Miscellaneous (travel, etc.)	11.00	0.03
- Interest on operating capital	46.35	0.12
Subtotal	<u>1,001.20</u>	<u>2.50</u>
<u>Harvesting and Marketing Costs</u>		
- Labor	72.75	0.18
- Fuel and Electricity	40.00	0.10
- Transportation	80.00	0.20
- Packing	500.00	1.25
- Promotion and brokerage	164.00	0.41
Subtotal	<u>856.75</u>	<u>2.14</u>
TOTAL VARIABLE COSTS	1,857.95	4.65
<u>Fixed Costs</u>		
- Depreciation	141.68	0.35
- Interest on investment	190.66	0.48
- Repairs and Maintenance	25.23	0.06
- Rent	84.00	0.21
- Insurance	6.20	0.02
TOTAL FIXED COSTS	<u>447.77</u>	<u>1.12</u>
TOTAL VARIABLE AND FIXED COSTS	<u>2,305.72</u>	<u>5.77</u>
Net return (loss)	<u>494.28</u>	<u>1.24</u>

Net returns for possible prices and yields are presented in Table 20. These values were computed assuming only harvesting, packaging, and promotion costs varied directly with yields. A yield of 300 masters and a price between \$6 and \$7 would have to be received to cover all costs (Table 20). The results presented are hypothetical and will vary depending on a producers' situation.

TABLE 20. NET INCOME (LOSS) PER ACRE AT VARIOUS PRICES AND YIELDS,
ONION PRODUCTION, CENTRAL RED RIVER VALLEY, NORTH DAKOTA, 1988

Yield	Average Price Received Per Master				
	5	6	7	8	9
Bags Sold/Acre					
100	(1,163)	(1,063)	(963)	(863)	(763)
200	(877)	(677)	(477)	(277)	(77)
300	(591)	(291)	9	309	609
400	(305)	95	495	895	1,295

Summary and Conclusions

The potential for competitive commercial production of onions in North Dakota was examined in this study. Total and seasonal U.S. production and foreign trade statistics were presented. Onions were divided by type: spring, summer non-storage, summer storage, and California. Market shares, seasonal prices, monthly shipments, and returns to storage were presented. Regional market share (production) and population along with per capita consumption were used to determine regional demand. Results indicate North Dakota lies in a net import region, suggesting a potential for North Dakota to produce onions. Transportation costs from North Dakota and competing regions were analyzed. North Dakota's advantage (disadvantage) in transportation costs versus other production regions were determined for the Fargo, Minneapolis, Chicago, New York, Atlanta, and Sioux Falls markets.

North Dakota onions have a transportation advantage over the Pacific Northwest and Denver origins for all the markets. Michigan onions have a transportation advantage over North Dakota for the Chicago, New York, and Atlanta markets.

North Dakota's competitiveness in any market is determined by production and transportation costs relative to production and transportation costs for other originating regions. However, since production costs for each region were not available, competitiveness comparisons were unobtainable.

A case study of a small vegetable production/marketing operation was analyzed. A vegetable operation was started in the central Red River Valley in 1987 and continued in 1988. Production in 1987 concentrated on carrots and shifted to onions in 1988. Results of the operation, including machinery utilization, production, sales, variable and fixed costs, packout, prices, and net return data were analyzed for onions. Operational problems became an integral part of the analysis.

An expanded model was developed from the case study data and followed the methodology of a Michigan State University study. The expanded model evaluated economic feasibility of a commercial-sized operation producing either carrots or onions. Assumptions used in the expanded model included a 300 acre farm with 250 tillable acres (100 acres planted to onions and 150 acres planted to other vegetables or small grains). Onion yields were estimated at 400 masters per acre using a \$7 per master market price.

Onions were estimated to have positive net returns. Onion production in the central Red River Valley of North Dakota was estimated to have per acre fixed and variable costs of \$448 and \$857, respectively. Onion receipts were estimated at \$2,800 per acre with estimated net returns of \$494 per acre. Net returns under various price and yield scenarios also were presented. Positive net returns were indicated for yields of 300 masters per acre and \$7 per master.

Feasibility studies estimate costs and returns using generally acceptable assumptions available from trade sources. However, an individual producer's costs and/or returns may vary significantly from assumptions used in this report. Therefore, each producer considering vegetable production and marketing should analyze the specific costs and returns that are inherent to their operation.
