FOREWORD

The work upon which this report is based was supported in part by funds from the Office of Nuclear Waste Isolation (ONWI), U.S. Department of Energy through the Western Rural Development Center (WRDC). The document, however, represents the views of the authors only and not necessarily those of the U.S. Department of Energy, the U.S. Department of Agriculture, or the Western Rural Development Center.

The purpose of this research was to test the adaptability of socioeconomic impact assessment models to alternative geographic settings. This report describes the data sources and procedures employed in adapting an existing North Dakota modeling framework for use in Wyoming. A companion document (Agricultural Economics Report No. 158) describes the logic, structure, data bases, and operational procedures of the North Dakota model. The intent of this report is to describe the data and procedures used for adaptation of NEDAM to Wyoming. User procedures are explained in the companion document (Agricultural Economics Report No. 158) and are not replicated in this report. Those wanting more information about "hands on" operation of the model should see the "User Procedures" section of that report.

The authors wish to express their appreciation to several individuals who made significant contributions to the successful completion of the study. Dr. James Finley, Project Manager for the Office of Nuclear Waste Isolation, and Dr. Steve Murdock, Project Director of the ONWI-WRDC project, were unfailing sources of encouragement throughout the course of the effort. Mr. John Goodier, Chief of Mineral Development, Wyoming State Department of Economic Development and Planning, made an invaluable contribution to the effort, particularly through his astute advice concerning data sources. Within the Department of Agricultural Economics of North Dakota State University, we gratefully acknowledge the contributions of Ms. Lori Cullen for her skillful and expeditious typing of the reports and Ms. Carol VavRosky for preparing the graphic materials. Finally, we express our appreciation to the state and local government officials and energy industry representatives who provided information essential to the analysis.

As always, our gratefulness to these individuals does not implicate them for any remaining errors or omissions.

Expansion and Adaptation of the North Dakota Economic-Demographic
Assessment Model (NEDAM) for Wyoming:

Technical Description

by

Randal C. Coon, Carlena F. Vocke, Robert A. Chase, Brenda L. Ekstrom,
William Ransom-Nelson, Richard W. Rathge, Thor A. Hertsgaard,
F. Larry Leistritz, Rebecca J. Vuchetich, Babu Ranganathan

Introduction

Recent increases in the development of natural resources such as coal extraction and conversion, along with projections of future development and utilization of Wyoming resources, have created concerns regarding the associated economic and social effects on rural areas. Declines in uranium and oil production the last two years have created similar concerns about negative impacts if this trend continues or earlier levels of production are not resumed. Federal, state, and local policy makers are requesting (and requiring) an increasing number of assessments of these social and economic impacts. In response, a number of socioeconomic impact assessment models have been developed to aid in the evaluation of public and private policies, to estimate the impacts of specific energy development projects, and to lend assistance in guiding local and regional planning.

The objective of this report is to describe the modified structure and data base of an existing computerized socioeconomic impact assessment model (North Dakota Economic-Demographic Assessment Model or NEDAM)¹ for adaptation to Wyoming. NEDAM was originally designed to provide estimates of economic, demographic, and fiscal changes at both the regional and local levels

¹For a complete description of NEDAM, see Leistritz, F. Larry, William Ransom-Nelson, Richard W. Rathge, Randal C. Coon, Robert A. Chase, Thor A. Hertsgaard, Steve H. Murdock, Rakesh Sharma, and Pai-Sung Yang, North Dakota Economic-Demographic Assessment Model (NEDAM): Technical Description, Agricultural Economics Report No. 158, Department of Agricultural Economics, North Dakota Agricultural Experiment Station, North Dakota State University, Fargo, September 1982.

resulting from alternative scenarios of energy resource use and development in North Dakota. NEDAM has successfully been adapted for Montana and used for economic impact assessment.² The adapted version of the model for Wyoming projects personal income at the multi-county regional level and estimates employment, population, and public sector costs and revenues at county and community levels. These projections are made on an annual basis for the period 1981 through 2005.

Study Area

The geographic scope of the project encompasses all 23 counties in Wyoming (Figure 1). Wyoming is bounded by Idaho to the west, Utah to the southwest, Colorado to the south, Nebraska and South Dakota to the east, and Montana to the north. The state's total land area is approximately 98,000 square miles, of which about 49 percent belongs to the federal government.³ The composition of federal land holdings varies from an Indian reservation and two national parks to extensive holdings of the U.S. Forest Service and the Bureau of Land Management.

The 1980 census population of Wyoming was 470,816 inhabitants, and the 1981 adjusted gross personal income was \$5.794 billion.⁴ Natural resource-based

Figure 1. The Six Functional Economic Regions in Wyoming

industries (agriculture, mining, lumber, and tourism) form the state's economic backbone.

Problem Statement

In recent years, the United States has increasingly turned toward developing its vast energy resources to decrease its dependence upon energy imports. This trend has spawned marked increases in extraction activity within the West, including Wyoming. As a result, the energy resource base in Wyoming has become a focal point in regional and extraregional resource conflict. Questions relating to the magnitude, manner, and effects of energy exploitation have been raised. Consequently, a detailed socioeconomic description of the state as it currently exists is needed to answer these questions. An analytical framework must be developed which is capable of assessing the direct and secondary socioeconomic impacts associated with alternative scenarios of energy development as proposed by various public and private entities in Wyoming. Likewise, similar questions and analytical requirements are evident in connection with the proposed development of minerals and other resources in Wyoming.

In response, a socioeconomic assessment model has been developed to meet these needs in Wyoming. It is a modified version of NEDAM, a model initially developed in 1976 to provide comprehensive information and projections of the economic and demographic effects of various existing and anticipated energy resource developments for state and local policy makers in North Dakota. This computerized, user-interactive model has the capability to make baseline and single- or multiple-project impact forecasts for any designated site in North Dakota. Though the basic structure of NEDAM remains essentially unchanged, model transfer necessitated extensive modification of the economic, demographic, and fiscal/service components.

The development of energy resources has prompted creation of a number of computerized socioeconomic assessment models such as NEDAM.⁵ While the number of assessment models has dramatically increased, few attempts have been made to adapt such models to settings other than those for which they were originally designed. Yet the need for such transfer and adaptation efforts is all too apparent, given the growing expense of developing an assessment model. In addition to savings in time and money, other advantages of model transfer and adaptation include the opportunity to expand and refine a model's structure and capabilities. Such refinements are seldom possible during initial model development. Given the number of existing models, such adaptations may well be more important than building additional assessment models.

Since all assessment models are developed for specific geographic areas, a successful adaptation effort will require incorporation and, where appropriate, modification to the unique characteristics (e.g., public revenue and expenditure patterns) of the particular study area. The processes involved in adapting a modeling system may vary from simply the alteration of its data base (i.e., to include data unique to the area of interest) to substantial and complex changes in its computational structure.⁶ An example of a successful

⁵For a review of selected impact assessment models, see Murdock, Steve H. and F. Larry Leistritz, "Selecting Socioeconomic Assessment Models: A Discussion of Criteria and Selected Models," Journal of Environmental Management, Vol. 10, 1980, pp. 241-252; Leistritz, F. Larry and Steve H. Murdock, The Socioeconomic Impact of Resource Development: Methods for Assessment, Westview Press, Boulder, Colorado, 1981; and Leistritz, F. Larry, Steve H. Murdock, and Robert A. Chase, "Socioeconomic Impact Assessment Models: Review and Evaluation," Impact Assessment Bulletin, Vol. 1, No. 4, 1982, pp. 35-49.

⁶For a description of the major steps in adapting a model and considerations for successful transfer, see House, Peter W. and John McLeod, Large-Scale Models for Policy Evaluation, John Wiley and Sons, New York, 1977; Murdock, Steve H. and F. Larry Leistritz, "Computerized Socioeconomic Assessment Models: Selection, Development, and Adaptation," (unpublished manuscript), Department of Rural Sociology, Texas A&M University, College Station, 1980; and Chase, Robert A. and F. Larry Leistritz, "A Case Study in Impact Assessment Model Adaptation," paper presented at the Mid-Continent Regional Science Association meeting, Vail, Colorado, June 1982.

transfer and adaptation effort is the Texas Assessment Modeling System (TAMS). Adapted from an earlier version of NEDAM, TAMS essentially retains the basic structure with the exception of extensive modification of the economic subcomponent, since the input-output model incorporated within the North Dakota version did not reflect the economic structure of eastern Texas. The other subcomponents in the model (i.e., demographic, fiscal, and service) were left relatively intact within the TAMS version. The adaptation of the NEDAM version to the Texas environment began in the fall of 1978, and the model became fully operational a year later. The relatively long time period for adaptation was, in large part, a result of extensive development of the Texas input-output model for use within the modeling system. Since its inception, the TAMS version has been widely used by state and local agencies for impact planning purposes.⁷

NEDAM also has been adapted for use in Montana. This adaptation involved a much shorter period of time than the TAMS effort because a new input-output model was not developed. The North Dakota input-output model was augmented with secondary data to replicate the Montana economy. After the data base for Montana was gathered, the model was basically operational because the major subcomponents were relatively unchanged. The Montana extension of NEDAM has been used extensively for impact analysis of coal extraction and conversion projects.⁸

⁷For a more complete discussion of the TAMS adaptation experience, see Murdock, Steve H., Lonnie L. Jones, F. Larry Leistritz, and Donald R. Andrews, "The Texas Assessment Modeling System (TAMS): A Case Study in Model Adaptation," Paper presented at the Conference on Computer Models and Forecasting Growth and Development, Jasper, Alberta, April 1980.

⁸For a complete description of the adaptation of NEDAM to Montana, see Chase, Robert A., et al., 1982, op. cit.

Outline of the Report

The remainder of this report consists of (1) a description of the methodology for the various data bases incorporated within the NEDAM extension and adaptation to Wyoming and a presentation of results from the adapted version, and (2) a concluding discussion on validation of the adapted version of the model.

In addition to the main text of the report, several appendices are provided. These appendices include (1) a discussion of data sources and procedures for the economic module; (2) a number of input-output (final demands, gross business volumes), employment, and productivity ratio tables; and (3) samples of the scenario specification procedure and output reports.

Methodology

The adapted version of NEDAM, designed to cover the 23 counties of Wyoming, has the capability to incorporate both energy- and nonenergy-related developments and allows for the evaluation of expansion, as well as decline, in the economic base. The user may select any one of the six designated functional regions or a group of counties (up to 15 counties) as the basis for model output.

The adapted Wyoming version provides for both baseline and impact projections for the period between 1981 and 2005. Baseline projections produced by the model indicate the expected response of economic and demographic factors in a designated region if the trends of the 1960s and 1970s were to continue to 2005. Given the historical trends of declining farm and ranch numbers and rural population, the baseline projections represent limited economic development opportunities for many areas in the region. These estimates provide the necessary background against which the impacts of resource developments are assessed.

The projections provided by the adapted model allow for the assessment of various socioeconomic impacts of single and multiple developments at alternative sites anywhere in the state. Essentially, the starting points for these projections are baseline population and economic data from the 1960s and 1970s. All changes from this initial baseline estimate for the years 1981 through 2005 are predicated on the expected expenditure and employment levels resulting from various developments.

The methodology used in expanding the NEDAM into Wyoming involves a number of steps:

1. Definition of the study area,
2. Description of the economic module,
3. Description of the demographic module,
4. Description of the residential allocation module, and
5. Modification of the fiscal impact model parameters.

These methods along with their results are described in the following sections.

Definition of the Study Area

Adaptation of the NEDAM involved applying the methodology and collecting the appropriate data for a defined area. The study area is defined as all 23 counties in Wyoming. Since model reports are furnished at the regional, county, and municipality levels, two major tasks had to be completed:

1. Selection of counties and communities for model inclusion, and
2. Disaggregation of the study area into functional economic regions.

The sources consulted and methods used in defining the study area are described below.

Community Selection

Essentially, the communities selected for model inclusion were either incorporated municipalities having a 1980 population greater than 300 people

or unincorporated municipalities with a 1980 count of at least 500 people. A total of 96 Wyoming communities were included in the extended model. In addition, 46 border communities in South Dakota, Nebraska, Colorado, Utah, Idaho, and Montana were included to account for interstate spillover effects of projects located close to (either side of) the border. Table 1 (and Appendix B, Table 1) lists both the counties and the communities included in the model.

Functional Economic Regions

In the NEDAM adaptation, the user may select either a group of counties or a designated region. The designated regions have been defined as functional economic areas (i.e., retail/wholesale trade areas) where each region is served by a major trade center. After consulting the available sources,⁹ the study area was disaggregated into six regions (Table 2). The boundaries of these regions were drawn along county boundaries to conform with available sources of statistical data. Figure 1 shows the study area as divided into six functional economic regions.

Description of the Economic Module

The economic module in the adapted version consists of six major components:

1. Economic Sector Delineation,
2. Input-Output (I-O) Technical and Interdependence Coefficients,
3. Baseline Economic Projections,

essentially tabulates and describes the linkages or interdependencies between various industrial groups within an economy. As such, the model requires the separation of the economy into these various groups called "sectors." The general framework of the model structures economic activity along two major divisions--suppliers and purchasers. Though these divisions are further subdivided into intermediate (processing) and primary (final payments) sectors and intermediate (processing) and final (final demand) purchasers, a further sector disaggregation is required.

The ideal sector delineation would allow unique recognition of supplier groups, each of which produces a homogeneous good. This ideal, however, is not feasible given the constraints of time, financing, and data. Hence, sector selection was determined to a large extent by the objectives of the study. Since the purpose was primarily to determine the impacts of resource development, most economic sectors such as retail trade and business services did not appear to require detailed disaggregation.

The input-output model used in the adapted version includes the 17 economic sectors of the North Dakota version along with three additional sectors: lumber and associated products, metal mining, and metal processing. The final sector delineations selected for this study are presented in Table 3. A description of the various sectors, their data sources, and their construction is provided in Appendix A.

1-0 Technical and Interdependence Coefficients

The description and analysis of the economy is based upon three components: transactions table, technical coefficients (direct requirements) table, and interdependence coefficients (direct and indirect requirements) table. Once data describing the commodities' flows between sectors are collected and tabulated, the technical coefficients can be easily derived. The difficulty, however, is preparing a transactions table that accurately describes the interdependencies among the economic sectors. Since the time and expense required to prepare the transactions table based on primary data are considerable, technical coefficients available from the North Dakota version and the Northwestern Colorado Input-Output Model¹⁰ were used to

¹⁰See Leistritz, et al., 1982, op. cit.; and Gray, S. L., J. R. McKean, and J. C. Weber, The Economy of Northwestern Colorado: Description and Analysis, Technical Report No. 25, Colorado Water Resources Research Institute, Colorado State University, Fort Collins, 1981.

approximate the interindustry relationships in Wyoming. The similarity of the economies of Wyoming and western North Dakota suggests that such a transfer is feasible. For the Wyoming regions, where sectors present in this area are not found in North Dakota (i.e., metallic mining, metal processing, and lumber), an existing I-O model from Colorado was selected as an appropriate source. The technical coefficients developed for Wyoming are provided in Table 4.

The technical coefficients matrix was subsequently used to derive interdependence coefficients which indicate the total (direct and indirect) input requirements per unit of output. The interdependence coefficients matrix

by definition is $(I-A)^{-1}$, where A is the matrix of technical coefficients and I is an identity matrix. Due to its expansion from 17 to 20 sectors (requiring a reinverting of the technical coefficients matrix), the Wyoming version has different interdependence coefficients for comparable sectors than the North Dakota version (Table 5).

Baseline Economic Projection Procedures

The economic module of the adapted version determines both baseline and impact projections. Baseline projections indicate the level of economic activity (measured by employment, personal income, and sales to final demand) associated with a continuation of current trends in the region's basic sectors. Baseline estimates constitute projections of future economic conditions likely to prevail in the area if no major resource development projects are initiated or closed. These projections are the essential base upon which the changes in economic activity associated with alternative scenarios of resource development are superimposed.

The general procedures for developing baseline economic projections involved projecting historic sales to final demand for the basic economic sectors through the year 2005. The I-O technical coefficients were applied to these final demand projections to obtain estimates of total output (gross business volume) for each sector for the respective years. Projected gross business volumes for each sector were divided by the projected productivity ratios for their respective sectors for each year to obtain estimated employment. In the final step, regional employment was allocated to counties and municipalities based on each entity's projected share of regional employment.

Baseline final demand projections were developed by first estimating the baseline sales to final demand for each sector for the period 1960 to 1980. The economic baseline for the study region was defined as the export sales of that

region's basic producing sectors to the "rest-of-the-world" without any major new resource development projects. The major components of the area's sales to final demand were sales by the agricultural (both crops and livestock), mining, and manufacturing sectors, plus federal government outlays and tourist expenditures. Historical estimates of sales to final demand were developed using data from secondary sources (see Appendix A) and techniques similar to those utilized elsewhere.¹¹ Final demand vectors for one Wyoming functional economic region (Region 1, Gillette-Sheridan) for the years 1960 to 1980 are presented in Table 6. Final demand vectors for the remaining regions and Wyoming totals are included in Appendix B, Tables 2-7. Projections of future levels of baseline activity were based on time series projections of the final demand vectors that existed in 1960 through 1980. Several time series regression analysis techniques were employed for each region and sector for the years 1960 through 1980 to arrive at the best set of projecting equations for the model. Equations estimated by robust regression analysis with an intercept adjustment were selected for use in the model (Table 7 and Appendix B, Tables 8-13). A detailed discussion of the regression analysis is included in Appendix A. As in the North Dakota version, projections for each final demand vector were obtained by linear extrapolations of the regression equations to the year 2005 for the respective sectors (Table 8 and Appendix B, Tables 14-19). These projections do not attempt to account for short-term deviations from historical trends. Rather, the projections represent the average final demand values that determine the levels of employment and population.

TABLE 7. REGRESSION EQUATIONS^a FOR PROJECTING FINAL DEMAND VECTORS FOR THE 20-SECTOR I-O MODEL, WYOMING REGION 1, (1980 = BASE DOLLARS), THOUSAND DOLLARS

Sector	Equation
(1) Ag, Livestock	$Y = -5,365,463 + 2784.09(X)$
(2) Ag, Crops	$Y = -150,254 + 80.85(X)$
(3) Metal Mining	$Y = 1050.0^b$
(4) Coal Mining	$Y = -789,774 + 512.39(X)$
(5) Pet/NG Exp/Ext	$Y = -35,332,480 + 18,072.9(X)$
(6) Nonmetallic Mining	$Y = -364,716 + 188.97(X)$
(7) Construction	$Y = -17,947.62 + 18.57(X)^c$
(8) Lumber and Assoc Prod	$Y = -983,157 + 503.77(X)$
(9) Ag Proc & Misc Manufacturing	$Y = -1,459,976 + 752.60(X)$
(10) Pet Refining	$Y = -5,037,873 + 2,589.64(X)$
(11) Metal Processing	$Y = 0^d$
(12) Transportation	$Y = 0^d$
(13) Comm & Public Utilities	$Y = 0^d$
(14) Electric Generation	$Y = -1,646,689 + 847.40(X)^e$
(15) Retail	$Y = -1,932,187 + 994.50(X)$
(16) Fin, Ins, Real Estate	$Y = 0^d$
(17) Business & Pers Service	$Y = -649,400 + 334.21(X)$
(18) Prof & Social Service	$Y = 0^d$
(19) Government	$Y = 0^d$
(20) Households	$Y = -4,904,891 + 2,533.06(X)$

^aRobust regression with intercept adjustment technique.

^bAverage of the last two years final demand vectors.

^cOrdinary least-squares regression technique was used because of the nature of the data.

^dAn economic sector having no sales for final demand.

^eOrdinary least-squares regression with an intercept adjustment technique was used because of the nature of the data.

Productivity (Gross Business Volume/Employment) Ratios

The productivity ratio for each economic sector refers to the gross business volume produced per full-time equivalent worker in that sector. Estimates were made of the gross business volume by economic sector for each region for the years 1960 to 1980 (Table 9 and Appendix B, Tables 20-25). Productivity ratios for each functional region were determined by dividing each sector's historic gross business volume (estimated by applying the interdependence coefficient matrix to the final demand vectors) by its

TABLE 8. PROJECTED FINAL DEMAND VECTORS FOR BASIC ECONOMIC SECTORS, WYOMING REGION 1, 1981, 1985, 1990, 1995, 2000, AND 2005, (1980 = BASE DOLLARS), MILLION DOLLARS

Sector	1981	1985	1990	1995	2000	2005

(11) Metal Processing	--	--	--	--	--	--
(14) Electric Generation	31.2	34.6	38.8	43.0	47.3	51.5
(15) Retail	36.9	40.9	45.9	50.8	55.9	60.8
(17) Business & Pers Service	12.3	13.7	15.3	17.0	18.7	20.4
(20) Households	110.6	120.7	133.4	146.0	158.7	171.4

employment¹² in the corresponding years (Table 10 and Appendix B, Tables 26-31).

The resulting estimates of gross business volume per worker for the respective sectors and years are shown in Table 11 and Appendix B, Tables 32-37.

Inconsistencies in the data used to disaggregate county employment to sectors resulted in sectors having gross business volume but no employment and occasionally vice versa.

These ratios of gross business volume per worker were projected through the year 2005 by using a method similar to that utilized in projecting final demand vectors.¹³ Robust regression analysis with an intercept adjustment provided estimation equations for each sector and each region (Table 12 and

¹²See Appendix A for data sources used in determining employment.

¹³These methods are similar to those employed in North Dakota. For further discussion see, Hertsgaard, T. A., S. H. Murdock, N. E. Toman, M. Henry, and R. Ludtke, REAP Economic-Demographic Model: Technical Description, North Dakota Regional Environmental Assessment Program, Bismarck, 1978; and Toman, N. E., S. H. Murdock, and T. A. Hertsgaard, REAP Economic-Demographic Model Version II: Technical Description, North Dakota Regional Environmental Assessment Program, Bismarck, 1979.

TABLE 12. REGRESSION EQUATIONS^a FOR PROJECTION OF GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR 20-SECTOR WYOMING I-O MODEL, REGION 1, (1980 = BASE DOLLARS), THOUSAND DOLLARS

Sector	Equation
(1) & (2) Agriculture	$Y = -7,668.54 + 3.96(X)$
(3) Metal Mining	$Y = 400^b$
(4) Coal Mining	$Y = -8,887.29 + 4.54(X)$
(5) Pet/NG Exp/Ext	$Y = -12,188.56 + 6.27(X)$
(6) Nonmetallic Mining	$Y = 34.389^b$
(7) Construction	$Y = 444.08 - 0.21(X)$
(8) Lumber and Assoc Prod	$Y = -1,122.63 + 0.58(X)$
(9) Ag Proc & Misc Manufacturing	$Y = -3,759.48 + 1.94(X)$
(10) Pet Refining	$Y = -27,683.15 + 14.34(X)$
(11) Metal Processing	$Y = 10,000^c$
(12) Transportation	$Y = -1,206.29 + 0.62(X)$
(13) Comm & Public Utilities	$Y = -3,382.65 + 1.75(X)$
(14) Electric Generation	$Y = -17,024.65 + 8.70(X)$
(15) Retail	$Y = -2,099.17 + 1.10(X)$
(16) Fin, Ins, Real Estate	$Y = -1,285.25 + 0.691(X)$
(17) Business & Pers Service	$Y = -157.27 + 0.09(X)$
(18) Prof & Social Service	$Y = -71.69 + 0.051(X)$
(19) Government	$Y = -462.03 + 0.24(X)$
(20) Households	$Y = 10,000^c$

^aRobust regression with intercept adjustment technique.

^bThe 1980 productivity ratio was used for the projection period.

^cBecause very little or no employment exists in this sector for Region 1, arbitrary, very large numbers were utilized in developing projections of baseline employment.

Appendix B, Tables 38-43). These equations were used to project gross business volume per worker to the year 2005. The resulting estimates of gross business volume/employment ratios projected through the year 2005 are shown for Region 1 in Table 13 and for the remaining regions in Appendix B, Tables 44-49.

County and Municipal Employment Allocators

Baseline employment is allocated to cities and counties on the basis of each city or county's projected share of total regional employment. Projected shares for each city were extrapolations of that city's share of county

TABLE 13. PROJECTED GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR WYOMING REGION 1, 1981, 1985, 1990, 1995, 2000, AND 2005 (1980 = BASE DOLLARS)

employment between 1960 and 1980.¹⁴ Since employment data were not available at the subcounty level, population was used as a proxy. Each city's share of employment was based on that city's share of total municipal population in the functional economic region from 1960 to 1980. Cities' shares were used to allocate the region's total nonagricultural employment among the cities in each region to 2005. In similar fashion, the region's agricultural employment was allocated to the counties in the region based on each county's share of the region's agricultural employment from 1960 to 1980. Agricultural employment projections to 2005 were based on the county's share in 1980. County and city allocators used in the adapted version are presented for Region 1 in Table 14 and for the remaining Regions in Appendix B, Tables 50-54.

Project-Specific Economic Parameters

Economic activity associated with the construction and operation of resource extraction and conversion projects was assumed to be largely additive to trends in baseline activity. The adapted version first computes the baseline economic activity in the region (along with its counties and municipalities) and then computes the economic activity associated with the development scenario specified by the user. Assessment of the economic impacts of a new resource project (or several projects) is based on a set of project-specific data assembled for each project. The project data file has been designed to allow rapid updating of information regarding specific projects (e.g., changes in construction timetables and labor requirements) and for the addition of information on new projects.

¹⁴Constraints were imposed on the extrapolation process such that the sum of all shares would equal 1.00 (i.e., 100 percent of regional employment) and that no city or county's share would be less than zero or more than one.

TABLE 14. PROJECTED CITY SHARE OF REGIONAL EMPLOYMENT BY CITY AND COUNTY, WYOMING REGION 1, 1980, 1985, 1990, 1995, AND 2000

The final demand vector of the site-specific data file for each project is applied to the input-output model. In the construction phase of a project, this consists of annual expenditures to the contract construction, retail trade, and household sectors. During the operational phase, annual expenditures are to the retail trade and household sectors. The construction phase final demand vector indicates the amount of injection of new dollars into the regional spending stream via the contract construction sector (for bid lettings to local contractors), retail trade sector (for supplies and materials purchased locally), and household sector (for wages and salaries to employees living in the area).

The data file for each energy development project that the user may specify contains the following set of specifications:

1. Project number,
2. Start date,
3. Location of project,
4. Project name and description,
5. Number of years after the start of construction that operation begins,
6. Land taken for plant and/or mine site,
7. Acres mined per year,
8. Land taken for urban uses,
9. Tons mined per year,
10. Kilowatt hours of electricity sold per year,
11. Cubic feet of synthetic natural gas sold per year,
12. Mine value for property tax purposes,
13. State share of Federal coal royalties,

14. Project final demand vectors,
 - a) Households,
 - b) Retail trade, and
 - c) Construction,
15. Direct Labor,
 - a) Construction (temporary workers), and
 - b) Operation or permanent workers.

Significant changes in sales for final demand and employment have occurred in Wyoming since the end of the baseline time period (1980). Public sentiment and unfavorable operating experiences, coupled with a substantial decrease in projected electric power consumption, have virtually halted construction of nuclear-powered electric generating facilities in the United States. This decline in projected nuclear power production has decreased demand for uranium, the mineral used to fuel reactors. Uranium mining in Wyoming quickly reflected this change with production and employment declining significantly from 1980 levels. The oil industry also has experienced some decline since 1980. Significant coal mine expansion and/or development along with coal-fired electric generation expansion has occurred since 1980. Project files were used to incorporate into the model industry decline and growth since the end of the historical baseline (1980), and to reflect future development or expansion only in the planning phase.

Industrial declines were handled as if the lower level of production occurred permanently. To accomplish this, the projected baseline final demand vector was set as a constant value reflecting reduced production. A project file was developed to allow the industry to resume its growth trend at a point in time when recovery would most likely occur. By handling declines in this manner, the project actually becomes part of the projected baseline economic activity of the region. Projected industry developments beyond baseline growth

were included as additional project files that could be added to the baseline project file. As the result of a comprehensive monitoring system, detailed data were available for existing and proposed mineral development projects in Wyoming.¹⁵

Extensive coal mine expansion and/or development has occurred in Wyoming between 1980 and 1983. Project files were developed to account for this expansion or development. These projects should be included in baseline economic activity runs. Development beyond this level is included as another project which can be superimposed upon the baseline project, if desired. Similar situations in other industries were treated in the same manner. Developments being planned also were set up as project files so they could be added to the baseline to assess impacts. Although various configurations can be selected for the types of resource development projects, characteristics of a typical coal mine expansion project in northeastern Wyoming are displayed in Appendix C.

Description of the Demographic Module

The demographic data base used in the model consists of four major components:

1. Detailed county population consisting of 75 age cohorts¹⁶
(single-year) by gender;
2. Birth rates by county of residence for six female five-year cohorts
from 15 to 45 years of age;

¹⁵Goodier, John T., Wyoming Mineral Development Monitoring System, Unpublished Data and Updates, Wyoming Department of Economic Planning and Development, Cheyenne, January 1983.

¹⁶Census information consisted of 104 age cohorts from 0 to 103. Cohorts 0 and 1 were added to form the first age cohort and cohorts 75 and over were added to form the last age cohort.

3. Survival rates of 75 age cohorts¹⁷ (single-year) by gender; and
4. Migration rates by county for age cohorts (single-year) over 64 by gender.

The data sources and methods used in the preparation of each of these components are described below.

Population by Age and Gender

Single-year cohort populations were derived from the STF 2A 1980 census data tape for Wyoming.¹⁸ The population counts are in 75 single-year age groups¹⁹ by male and female for each county in 1980.

Birth Rates

Three sets of age-specific birth rates were computed for each county in Wyoming for use in the model. These rates were computed using the general formula:

$$ASFR_i = \frac{(i^B_{1979} + i^B_{1980} + i^B_{1981})/3}{i^{FP}_{1980}}$$

where: $ASFR_i$ = age-specific fertility rates for females in age group (cohort) i ;

$(i^B_{1979, 1980, 1981})/3$ = average number of births to females in age group i in 1979, 1980, and 1981;

i^{FP}_{1980} = female population of age group i in 1980.

Data on births were obtained from the Wyoming Department of Health and Social Services, Bureau of Vital Statistics; 1980 data on the number of females were

¹⁷Ibid.

¹⁸Ibid.

¹⁹Ibid.

obtained from the 1980 STF 2A census data tape for Wyoming. The use of an average number of births for a three-year period is a standard procedure²⁰ used to eliminate the effects of bias due to chance fluctuations in the number of births from year to year.

The three sets of rates computed for the projection period for each county were patterned after completed levels of fertility of 1.8, 2.1, and 2.5 births per female. These total fertility levels are the sum of a set of age-specific fertility rates for women in the childbearing ages that would result if each female were to experience a given set of age-specific rates for each age group as she aged through her reproductive lifetime. Six five-year cohort rates were calculated for each county for 1980. A 25-year national fertility trend for the corresponding six five-year cohorts (i.e., women 15 to 45 years of age) was utilized to project total fertility over time.²¹ The age-specific national fertility trends were applied to the ratio of county age-specific fertility rates for 1980 for each projection year resulting in a set of age-specific fertility rates for each county and each level of completed fertility.²² An example of county fertility rates for 1980 is provided in Table 15 for Campbell County.

TABLE 15. FERTILITY RATES^a FOR CAMPBELL COUNTY, WYOMING, 1980

Age Group	Birth Rate
15-19 ^b	.029520
20-24	.066912
25-29	.103729
30-34	.057471
35-39	.017760
40-44 ^c	.001789

^aUsing national completed levels of fertility of 2.1 births per female.

^bBirths to women less than 15 years of age are included in this category.

^cBirths to women over 44 years of age are included in this category.

Survival Rates

Survival rates for 15 age and gender cohorts (Table 16) were determined from a 1980 life table for Wyoming.²³ An average of total deaths in each cohort from 1979 through 1981 was used to reduce yearly fluctuations. The survival rates for the 15 age-gender cohorts were disaggregated into 75 single-year age-gender cohorts conforming to the detailed population.

The relatively small variation in mortality from one area to another allowed the application of state survival rates to all of the counties. These rates were computed using the life table survival rate method:

$$S_{x, x+t} = \frac{L_{x+t}}{L_x}$$

where: $S_{x, x+t}$ = probability of a member of a cohort surviving from the time period x to $x+t$;

L_{x+t} = number of persons in the cohort alive at the end of the period, $x+t$;

L_x = number of persons in the cohort alive at the beginning of the period, x .

²³Computed from data supplied by the Vital Statistics Division, Department of Health and Social Services, Unpublished Data, Cheyenne, Wyoming, 1982. The model applies one rate to all individuals over the age of 70, thus, this rate is adjusted downward to avoid inflating deaths in this age category due to its cumulative quality.

TABLE 16. WYOMING SURVIVAL RATES BY AGE AND GENDER

Age	Male	Female
0-4	0.999686	0.999791
5-9	0.999689	0.999867
10-14	0.999449	0.999816
15-19	0.998571	0.999651
20-24	0.998769	0.999708
25-29	0.999771	0.999702
30-34	0.998451	0.999517
35-39	0.998252	0.999230
40-44	0.997839	0.998975
45-49	0.996213	0.997965
50-54	0.995450	0.997585
55-59	0.992328	0.995825
60-64	0.990448	0.993670
65-69	0.983648	0.988281
70+	0.981548	0.985138

$L_x + t$ and L_x are derived from the appropriate column of a standard life table. Survival rates for the 1979 to 1981 period were assumed to prevail throughout the projection period.

Migration Rates

Migration rates were not specified for age-gender cohorts 1 to 65 because the employment-based method determines migration. The interface component, described later in the report, uses a comparison procedure²⁴ between required employment and available work force, ages 15 to 64, to determine yearly net migration. The migration of individuals under age 15 was determined as a direct result of net work force migration. A profile of a migrating family was developed from survey data and applied to in- and out-migrants providing migration levels for age-gender cohorts from 1 to 14.

Migration rates were utilized for age-gender cohorts (single-year) 65 to 74+. Rates were computed for each county in 1980 from two five-year

²⁴For a more detailed discussion of migration procedures, see pages 41-44 of Leistritz, et al., 1982, op. cit.

age-gender cohorts, 65-69 and 70-74+. These rates were computed by using an average of the rates computed by forward and reverse survival rate methods,²⁵ using data from the 1970 census first count, file B and STF 2A for 1980. Migration rates for 1980 were assumed to prevail throughout the projection period. The 1980 net migration rates for Campbell County are provided in Table 17.

TABLE 17. MIGRATION RATES FOR CAMPBELL COUNTY, WYOMING, 1980

Age Group	Male	Female
65	-.031257	-.019933

74+	-.032900	.003675

Description of the Residential Allocation Module

The residential allocation component of the model estimates the probable settlement patterns of in-migrating workers and their dependents.²⁶ The allocations were made at the municipal level using a gravity model. Use of this model assumed that the number of in-migrants moving to a city will be inversely related to the distance between the city and the employment site. In addition, qualitative factors were assumed to exist among settlements and to affect workers' choices. Previously collected data on settlement patterns

²⁵Leistritz, F. Larry, and Steven H. Murdock, 1981, op. cit.; Shryock, H. S., and J. S. Siegel, 1973, op. cit.; and Bowles, G. K., C. L. Beale, and E. S. Lee, Net Migration of the Population, 1960-70 by Age, Sex, and Color, University of Georgia Printing Department, Athens, 1975.

²⁶Worker demographic characteristics and labor force participation rates used in the Wyoming version are equivalent to those in the North Dakota version. See Leistritz, et al., 1982, op. cit.

of workers were used as a basis for estimating parameters for the gravity model.²⁷ In symbolic form, these assumptions may be stated as follows for each site:

$$M_i = \frac{\left[\frac{E_{Bt-1} + fE_{Ct-2} + E_{Ot-1} + E_{It-1}}{d_{ij}^a} \right] W_i}{\sum_{i=1}^n \left[\frac{E_{Bt-1} + fE_{Ct-2} + E_{Ot-1} + E_{It-1}}{d_{ij}^a} \right] W_i}$$

where: M_i = the fraction of the project-related employees who reside in city i ;

E_B , E_C , E_O , and E_I are baseline, construction, operating, and secondary (indirect and induced) employment, respectively, in the previous year (except for construction employment, which is two years previous);

f = a fraction applied to construction employment in the year $t-2$;

d_{ij}^a = the distance from municipality i to the location of project j raised to the power a ;

W_i = the relative qualitative attractiveness of city i .

The residential allocation calculations by the gravity model include 96 municipalities within Wyoming as an initial set, plus 46 adjoining municipalities in South Dakota, Nebraska, Colorado, Utah, Idaho, and

²⁷Leholm, Arlen G., F. Larry Leistritz, and James S. Wieland, Profile of North Dakota's Electric Power Plant Construction Work Force, Agricultural Economics Statistical Report No. 22, Department of Agricultural Economics, North Dakota Agricultural Experiment Station, North Dakota State University, Fargo, 1976; Mountain West Research, Inc., Construction Worker Profile, Old West Regional Commission, Washington, D.C., December 1975; and Wieland, James S., "Socioeconomic Characteristics and Settlement Patterns Associated with Operating and Construction Work Forces in North Dakota, South Dakota, and Montana," Unpublished M.S. Thesis, Department of Agricultural Economics, North Dakota State University, Fargo, 1977.

Montana.²⁸ This set of municipalities is further reduced to only those cities within this group that fall within a 150-mile radius of a given project site.²⁹ Non-Wyoming municipalities are allowed to attract population away from Wyoming during gravity model calculations, but no annual calculations of changes in the population of non-Wyoming cities are made. These cities are assumed to have an employment base equal to their 1980 estimated employment plus construction, operation, and secondary workers that are projected to migrate to these cities.

As in the North Dakota version of the model, the user may specify values for the power (a) to which distance is raised. Separate gravity model allocations are made for each type of worker. Unless the user specifies otherwise, the gravity powers are 1.5 for construction workers, 2.9 for operating workers, and 1.6 for project-related secondary workers. This results in a smaller proportion of construction workers than operating workers being allocated to municipalities near the plant site. Slightly more indirect workers than construction workers are allocated to nearby cities.

The gravity model allocates construction, operation, and secondary workers to communities as a factor of commuting distance to the site of a project, but secondary workers are assumed to both reside and work in the community to which they have been allocated. The residential allocation module is computed for each year there is project-related in-migration, using appropriate previous year's employment of each type for each city.

Modification of the Fiscal Impact Module

Fiscal impact analysis is often used to describe the comparison between revenue and expenditure flows over time as communities respond to energy

²⁸For a listing of the municipalities included in the Wyoming adaptation, see Appendix B, Table 1.

²⁹A 142 x 142 matrix was created showing the distances (highway mileage) between all communities included in the Wyoming version.

resource and industrial development projects. The primary focus is on the public sector costs and revenues associated with a particular project. Using traditional forms of cash-flow analysis in determining costs and revenues, the typical result of fiscal impact analysis is a statement of net surplus or deficit. The key features of this analysis are (1) an exclusive focus on the revenues received and the costs incurred by governmental units, and (2) inclusion of the distribution of costs and revenues through time.³⁰

The fiscal implications of any energy development project depend on a number of factors, notably project characteristics (e.g., the magnitude of investment and the size and scheduling of the work force), site area characteristics (e.g., state and local tax structures and the capacity of existing service facilities), and the nature of the economic and demographic effects resulting from the project.

Although the basic structure of the North Dakota fiscal impact module remains relatively intact in the Wyoming version, various fiscal functions, which estimate the public sector costs and revenues associated with energy development projects, have been modified to conform to those site area characteristics unique to Wyoming. The data sources³¹ and methods used in modifying the fiscal model parameters are described below.

³⁰Leistritz, F. Larry and Steve H. Murdock, 1981, op. cit.

³¹The general sources utilized in modifying the fiscal module for Wyoming were: Goodier, John T. and Dale S. Hoffman, Wyoming Mineral Yearbook, 1982, Mineral Division, State Department of Economic Planning and Development, Cheyenne, 1982; Thompson, Layton S. and Willard D. Shutz, The Taxation and Revenue System of State and Local Governments in Wyoming, Wyoming Agricultural Experiment Station, University of Wyoming, Laramie, 1978; Voelker, Stanley W., State and Local Taxes Affected by Energy Developments in Selected Western States, EPA-600/7-81-005, U.S. Environmental Protection Agency, Denver, 1980; Department of Revenue and Taxation, Annual Report of the Wyoming Department of Revenue and Taxation, Cheyenne, 1982; and Ad Valorem Tax Division, Annual Report of the Wyoming State Board of Equalization, Department of Revenue and Taxation, Cheyenne, 1982.

Revenue Estimation

The principal difference between the North Dakota and Wyoming taxation systems is that Wyoming does not have a personal or corporate income tax. The three income sources that yielded the greatest revenue for Wyoming in 1980 were property taxes (44 percent); sales taxes (24 percent); and mineral severance taxes (15.5 percent), primarily oil and gas, coal, and uranium. Together, these taxes accounted for over \$568 million or nearly 85 percent of the total tax revenue collected in 1980.³²

Changes in Wyoming's state and local tax collections were obtained by applying the appropriate tax rate to the estimated change in the relevant tax base. A discussion of the various tax estimators for the state and local governments used in the Wyoming version is presented below.

State Revenue Sources.

1. State Sales and Use Tax: The state sales and use tax estimator is 3.71 percent of the gross business volumes of the retail, business and personal services, and petroleum and natural gas exploration/extraction sectors.³³ This estimator was derived by comparing the sales and use tax collections to the estimated gross business volumes of these sectors for the years 1976 to 1980.

The sales tax applies not only to retail sales of tangible commodities, but also to certain specified services, notably business and personal services, and various exploration and extraction services to the petroleum industry. The use tax imposed on purchases made outside Wyoming for first use, storage, or consumption within the state complements the sales tax.

2. Other State-Collected Taxes: The various highway taxes, the liquor tax, and the tobacco tax were estimated on a per capita basis from data

³²Department of Revenue and Taxation, 1982, op. cit.

³³Ibid.

obtained from the State Department of Revenue and Taxation and the Wyoming Liquor Commission.³⁴ Highway taxes were defined, for purposes of this study, to include revenues from the motor vehicle registration fees, gross vehicle weight fees, and the motor vehicle fuel tax. The per capita estimates, in 1980 prices, for the various taxes were:

Highway Taxes	\$141.87
Cigarette Tax	\$ 12.34
Liquor Tax	\$ 13.11

3. Mineral Severance Taxes: Although most of the excise taxes on minerals have remained relatively unchanged since 1977, the 1981 legislature imposed new excise taxes on the privilege of mining in the state.³⁵ These were combined with existing severance and excise taxes and are described in Table 18. The excise taxes are essentially levied on the gross proceeds of minerals in Wyoming. Gross proceeds are defined as the value of the mineral at the mine, prior to processing and transportation. State excise taxes are in addition to the ad valorem property taxes which also are levied on gross proceeds.

- a. Coal. As of 1978, state excise taxes levied on Wyoming coal have been 10.5 percent of gross proceeds. The effective tax rate of 10.5 percent is equivalent to a tax of \$.874 tax per ton of coal, in 1980 prices. The excise taxes are earmarked for specific uses except for 2 percent which accrues to the state's general fund.³⁶

³⁶Goodier, John T. and Dale S. Hoffman, 1982, op. cit.

TABLE 18. EXCISE TAXES LEVIED AGAINST MINERALS, WYOMING, 1981

Disposition of Revenues	Percent of Gross Proceeds					
	Coal	Uranium	Trona	Petroleum and Natural Gas	Stripper Oil	Other Minerals
General Fund	2.0	2.0	2.0	2.0	--	2.0
Permanent Mineral Trust Fund	2.5	2.0	2.0	2.17	2.17	--
Coal Tax Revenue Account	2.0	--	--	--	--	--
Capital Facilities Revenue Account	1.5	1.5	1.5	--	--	--
Water Development Account	1.5	--	--	.16	.17	--
Highway Fund	1.0	--	--	.67	.66	--
Agency and Trust--Cities and Towns	--	--	--	.75	.75	--
Agency and Trust--Counties	<u>--</u>	<u>--</u>	<u>--</u>	<u>.25</u>	<u>.25</u>	<u>--</u>
Total Levies	10.5	5.5	5.5	6.00	4.00	2.0

SOURCE: Department of Revenue and Taxation, Annual Report of the Wyoming Department of Revenue and Taxation, Cheyenne, 1982.

The permanent mineral trust fund remains inviolate, although all income from the fund is deposited in the state's general fund. The levy for the coal tax revenue account, initially called the coal tax for impact assistance, is 2 percent. The funds, administered by the Wyoming Farm Board, are used to finance water, sewer, highway, and road and street projects in areas impacted by coal production. No less than 50 percent of these revenues are to be allocated to finance state highway, county road, or city street projects. This tax is due to expire when cumulative collections total \$160 million.

Funds in the capital facilities revenue account are used for the designing, maintaining, operating, equipping, repairing, and financing of capital facilities for state government operations. The tax levy will expire when taxes collected total \$250 million.

Receipts from the 1.5 percent tax on water development projects are deposited in the water development account. When this account totals \$100 million, proceeds are to be deposited in the general fund until the water fund balance is reduced to \$50 million. The 1 percent levy for the highway fund will expire when the account reaches \$6 million.

- b. Oil and Stripper Oil. As of 1981, the state excise taxes levied on extracted oil in Wyoming have amounted to 4.0 percent of the gross proceeds. That legislative session enacted an additional excise tax of 2 percent of the gross proceeds on the extracted oil and gas. The revenue collected from this additional 2 percent tax is transferred to the Trust and Agency Fund with the resultant

distribution shown in Table 18.³⁷ In 1980 prices, the effective tax rate (including stripper oil) of 9.15 percent was equivalent to \$1.56 tax per barrel of oil.

c. Natural Gas. Similarly, state excise taxes against natural gas extracted in Wyoming increased to 6 percent in 1981. In 1980 prices, the effective tax rate of 4 percent amounted to \$.055 per thousand cubic feet (mcf) of natural gas.

d. Uranium. The effective tax rate of 5.5 percent amounted to \$.69 per ton of uranium in 1980 prices.

e. Trona. The effective tax rate of 5.5 percent on gross proceeds amounted to \$.509 per ton of trona in 1980 prices.

4. Federal Mineral Royalties: The 1976 federal leasing law mandates that 50 percent of the royalties collected from development of federal lands be returned to the state. Cumulative royalty payments from the federal government for mineral operations in Wyoming (through December 1980) amounted to over \$349 million. Federal royalties are not reported separately by commodity or specific mining operation. These receipts are distributed among six funds: school foundation programs (37.5 percent); state highway fund (26.25 percent); county highway fund (2.25 percent); incorporated municipalities (7.5 percent); capital construction (19.75 percent); and the University of Wyoming (6.75 percent).

Local Revenue Sources.

1. Ad Valorem Property Tax: The local property tax estimator is 1.50 percent of the market value of the property. This estimator was based on the 1980 state average sales assessment ratio of 23.21 percent and the state average mill rate of 64.21.³⁸ Added property tax revenue was determined by applying

³⁷Department of Revenue and Taxation, 1982, op. cit.

³⁸Ad Valorem Tax Division, 1982, op. cit.

the estimator to the projected market value of new business structures and residences.

The estimated investment cost for houses, apartments, and business structures was used as estimated market value for those structures, and the market value for mobile homes was estimated at one-half the purchase price. Capital investment in business structures was estimated by Prestgard³⁹ at \$0.22 per dollar of gross business volume. The estimates of investment cost per unit in 1980 prices are equivalent to those used in the North Dakota version:

Houses	\$59,157
Apartments	\$26,162
Mobile Homes	\$13,392

In 1980, Wyoming property tax revenues were distributed in the following manner:⁴⁰

<u>Disposition</u>	<u>Percent</u>
Schools	67.81
Counties	17.45
Foundation Program	9.27
Special Districts	3.74
Municipal	1.73

Wyoming also subjects the gross proceeds of coal mines to the ad valorem property tax. Property tax revenues from mine property were estimated in 1980 prices as follows:⁴¹

Capital investment in mine = (\$8.32 x size of mine in tons per year)
Mine value = (capital investment x 100 percent)
Tax revenue = (mine value x 1.5 percent)

2. Optional Sales Tax: The 1973 Legislative Session provided counties with the authority, by election, to impose an optional sales tax of 1 percent in addition to the existing state sales tax. This tax is generally applied to

³⁹Prestgard, P. G., "Effect of Coal Development on Public Costs in North Dakota," Unpublished M.S. Thesis, Department of Agricultural Economics, North Dakota State University, Fargo, 1974.

⁴⁰Ad Valorem Tax Division, 1982, op. cit.

⁴¹Goodier, J. T. and D. S. Hoffman, 1982, op. cit.

the sale, lease, or rental of tangible personal property. Of the 23 Wyoming counties, over two-thirds have authorized an optional sales tax. The following is a list of counties imposing the optional tax and their effective dates.⁴²

<u>County Name</u>	<u>Effective Date</u>
Campbell	12-01-76
Carbon	12-01-77
Converse	03-01-76
Crook	01-01-79
Hot Springs	12-01-76
Johnson	11-01-79
Laramie	12-01-77
Lincoln	11-01-79
Natrona	12-01-74
Niobrara	12-01-76
Platte	12-01-76
Sheridan	01-01-79
Sweetwater	01-02-74
Teton	11-22-73
Uinta	07-01-76
Weston	09-01-75

3. Sales and Use Tax Transfers from State: The 1975 Legislative Session provided that one-third of the state sales tax and one-sixth of the use tax collections be distributed to counties, cities, and towns. The percentage distributed to each county is based on the percentage of sales and use tax collections in each county. Within each county, the tax disbursement is made according to the following formulas:

(a) For counties--
$$\frac{\text{Population Outside Incorporated City Limits}}{\text{Total Population of the County}}$$

(b) For cities and towns--
$$\frac{\text{Population Inside Incorporated City Limits}}{\text{Total Population of the County}}$$

In like manner, the entire proceeds from the 1 percent option tax for counties is distributed to counties, cities, and towns.

⁴²Department of Revenue and Taxation, 1982, op. cit.

4. Educational Fund Transfers From State: Transfers were estimated on the basis of per pupil payments for elementary and secondary students as follows:⁴³

<u>Elementary</u> <u>Number of Students</u>	<u>Transfer Payment/Student</u> <u>1980</u>
>1000	\$ 257.77
101-999	\$1,288.85
<100	\$1,549.60
<u>Secondary</u> <u>Number of Students</u>	<u>Transfer Payment/Student</u> <u>1980</u>
>550	\$ 704.36
151-549	\$1,291.33
<150	\$1,589.33

5. Highway Fund Transfers From State: Transfers estimated in 1980 dollars as a per capita share of state highway taxes were:⁴⁴

County share per capita = \$15.32
Municipal share per capita = \$ 6.92

6. Cigarette Tax Transfers From State: Transfers, in 1980 dollars, estimated as a per capita share of the state cigarette tax were:⁴⁵

County share per capita = \$1.42
Municipal share per capita = \$9.88

7. Mineral Severance Tax Transfer From State: (See State Revenues, Mineral Severance Tax Section).

8. Federal Revenue Sharing Transfers: These were assumed equivalent to North Dakota's due to application of a national formula to two very similar states. Estimates made in 1980 dollars of average per capita transfers for counties and municipalities were:

Counties = \$10.94 per capita
Municipalities = \$ 6.65 per capita

⁴³Mottonen, Lois, Director of Fiscal Services, Personal Communication, State Department of Education, Cheyenne, Wyoming, January 1983; and Thompson, L. S. and W. D. Schultz, 1978, op. cit.

⁴⁴Wyoming State Highway Department, "Current Fund: Assets, Budgeted Receipts, and Federal Aid Balances," Cheyenne, September 30, 1980.

⁴⁵Department of Revenue and Taxation, 1982, op. cit.

9. User Fees: User fee revenues, estimated on the basis of average per household expenditures for water, sewer, and solid waste, are the same as used in North Dakota (i.e., \$165.91 in 1980 dollars).

10. Special Assessments: Revenues from special assessments were estimated by amortizing the capital investments for streets, water, sewer, and solid wastes at 7 percent interest for 20 years.

Cost Estimation

The effect of an energy development project on local government costs is determined by a number of factors, with the extent of local population growth and level of excess capacity in local public service infrastructure being the most important. A description of cost calculations and cost estimating equations is presented below.

State Costs.

1. Educational Fund Transfers to School Districts: Cost to the state was estimated as the total of per pupil payments (see the local revenue, educational fund transfers from the state section).

2. Highway System Operating Expenditures: Increased operating costs for all highway department functions were estimated on a per capita basis to be \$322.50 in 1980 dollars.⁴⁶

3. General Government Functions: As in the North Dakota version, these costs were estimated to be \$480.10 per capita in 1980 dollars.

4. Capital Investment in Highway System: Capital costs for highway improvement were estimated on the basis of a per in-migrating operating worker cost of \$29,987 in 1980 prices, adjusted annually for inflation.⁴⁷

⁴⁶Department of Revenue and Taxation, 1982, op. cit.

⁴⁷Leistritz, et al., 1982, op. cit.

Local Costs.

1. Schools:

- a. Operating expenditures were estimated as cost per pupil in 1980 prices where both elementary and secondary per pupil costs were estimated on the basis of the number of new secondary students as follows:⁴⁸

<u>Number of Additional High School Students</u>	<u>Per Pupil Cost</u>
>200	\$1,504.90
150-199	\$1,617.71
100-149	\$1,811.84
75- 99	\$2,123.68
51- 74	\$2,554.29
≤ 50	\$2,443.60

- b. Expansion costs of school facilities in Wyoming were assumed to be equivalent to those in North Dakota, i.e., cost per student basis in 1980 dollars.⁴⁹

2. Streets, Distribution and Treatment of Water, Waste-Water Systems and Treatment, and Solid Waste Disposal: Cost estimates for infrastructure were assumed to be equivalent to those in North Dakota's version.

3. Law Enforcement, Fire Protection, and Other Local Government Functions: Operational expenditures for municipal and county government functions were assumed to be equivalent to those in North Dakota. Cost estimates from regression equations in 1980 prices are:

County Social Services	\$ 7.45
County Law Enforcement	\$ 5.78
County Highway Maintenance	\$ 29.02
County General Government	\$ 94.86
City Fire Protection	\$ 24.91
City Police Protection	\$ 31.34
City General Government	\$208.00

⁴⁸Mottonen, Lois, 1983, op. cit.; and Thompson, L. S. and W. D. Schultz, 1978, op. cit.

⁴⁹Leistritz, et al., 1982, op. cit.

Evaluation of the Model

An important factor in determining a model's usefulness is its degree of reliability in simulating socioeconomic changes in the study region. Confidence in a given impact assessment model can be gained in three general ways: (1) critically assessing its theoretical basis, assumptions, data sources, and computational procedures; (2) investigating its response to perturbations; and (3) testing its ability to reproduce historical data.⁵⁰ Most impact assessment models, including NEDAM, have been subjected to the first two types of evaluation. The third general form, historical simulation, was used in evaluating the performance of the Wyoming version of NEDAM. This method involves choosing a past period for which the values of the variables estimated by the model are known. The model was provided with the historical values of the input variables and simulated over this period. The resultant values estimated by the model then were compared to the actual values by applying a number of statistical tests (including Theil's U_1 coefficient, mean absolute error, mean error, and R^2 coefficient)⁵¹ to evaluate the "goodness of fit."

The NEDAM adaptation to Wyoming was evaluated by determining how closely the model reproduces historical personal income as reported by the Department of Commerce.⁵² In brief review, the model estimates personal income for each

⁵⁰Leistritz, F. Larry, Steve H. Murdock, Donald M. Senechal, and Thor A. Hertsgaard, "Computerized Socioeconomic Impact Models: Usefulness and Limitations," paper presented at Conference on Computer Models for Forecasting Socioeconomic Impacts of Growth and Development, Jasper, Alberta, April 1980.

Thesis, Department of Agricultural Economics, North Dakota State University, Fargo, 1971; and Martinez Salazar, Angel S., "A Methodology for the Evaluation of the Economic-Demographic Simulation Models," Unpublished M.S. Thesis, Department of Agricultural Economics, North Dakota State University, Fargo, 1981.

⁵²Bureau of Economic Analysis, Personal Income by Place of Residence, Wyoming, U.S. Department of Commerce, U.S. Government Printing Office, Washington, D.C., 1962, 1965-1980.

of the years (1960-1980) for the six regions and Wyoming using input-output techniques. The interdependence coefficients developed elsewhere in North Dakota⁵³ and northwestern Colorado⁵⁴ were applied to final demand vectors computed for the state or regions. These estimates of gross business volume (in the household sector row) for each economic sector (or column) were simply those levels of business activity generated by sales for final demand (i.e., exports). The gross business volume for the household sector, except for minor definitional differences, is equivalent to personal income. For each year, the total personal income generated in the region is the summation of personal incomes resulting from final sales (gross business volumes in the household sector row) by the column sectors.

The results of these calculations for each year were compared with estimates of personal income assembled by the Department of Commerce. These results for Wyoming and its six regions are presented in Table 19 (and Appendix B, Tables 55-60). The differences, expressed as percentages of the Department of Commerce estimates, indicate consistent patterns for each region and the state. A possible interpretation of this consistency is the interdependence coefficients were simulating the economy correctly, but sales for final demand vectors were either being over- or underestimated.

Statistical tests were used to evaluate performance of the model. Results of these tests are presented for all six regions and the state (Table 20). Absolute average difference indicated more variation at the regional level than for the state as a whole, with all but one of the regions having less than an 18 percent difference. The mean average difference indicated Regions 2, 3, and 5 were slightly underestimated while remaining regions were

1979	651,812	655,643	0.6
1980	749,601	806,675	7.6
Average Difference			5.0

Mean = .782 (S.D. = 6.691)

$U_1 = .033$

slightly overestimated. Wyoming personal income was underestimated by the adapted model by 6.4 percent during the 1960 to 1980 period. Standard deviations for the regions ranged from 5.97 to 21.13, and the state value was 5.50. Theil's coefficients for the regions ranged from .032 to .205, and the state value was .056. These values (all very close to 0.0) indicate the model performs quite well and can be used with confidence for predictive purposes.

Sales for final demand vectors for Region 2 have a significant downward bias. The divergence was consistent over the time period tested with the mean average difference being -28.0 percent. Underestimating sales for final demand for a region is quite possible when a major trade center is located within the

TABLE 20. COMPARISON OF STATISTICAL TESTS FOR E-D MODEL PERSONAL INCOME ESTIMATION, WYOMING REGIONS 1-6, AND STATE, FOR TIME PERIOD 1960-1980

Region	Average Absolute Difference ^a	Mean Average Difference ^b	Standard Deviation ^c	Theil Coefficient ^d
1	5.0%	0.8%	6.69	.032
2	28.0	-28.0	5.97	.205
3	9.6	- 6.8	8.52	.045
4	9.2	4.6	10.69	.035
5	17.5	- 1.2	21.13	.155
6	13.5	13.5	6.21	.066
State	7.3	- 6.4	5.50	.056

^aAverage absolute difference is the sum of the absolute values of the percent difference of I-0 estimates and historic data divided by the number of observations.

^bMean average difference is the sum of the percent difference of the I-0 estimate and historic data divided by the number of observations.

^cStandard deviation is for the difference of the I-0 estimate and historic data.

^dTheil's coefficient calculated using the formula:

$$U_1 = \frac{\sqrt{\frac{1}{T} \sum (Y_s - Y_a)^2}}{\sqrt{\frac{1}{T} \sum (Y_s)^2} + \sqrt{\frac{1}{T} \sum (Y_a)^2}}$$

where: T = time period

Y^s = simulated value of Y

Y^a = actual value of Y

area, as is Casper in Region 2. Expenditures by residents of other regions, presumably in major trade centers, are made on those goods and services not available (perceived or actual) in their communities. Casper also serves as a major headquarters for the energy industry of Wyoming, and some Casper-based firms have operations in Colorado, Montana, and North Dakota as well. Energy industry expenditures to Casper could not all be captured in baseline export sales for final demand.

Personal income estimates for Region 3 also were underestimated with a mean average difference of -6.8 percent. Cheyenne, a major trade center located in this region, probably caused interregional spillover effects that resulted in the underestimation of Region 3. In addition, the possible

expansion of the Cheyenne trade area into Nebraska and Colorado contributed to the problem of determining the economic base.

The remaining four regions in Wyoming were estimated quite accurately.⁵⁵ Regions 1, 4, and 6 were slightly overestimated, and Region 5 was only slightly underestimated. Statistical tests on results from these four regions indicate the model accurately replicates the Wyoming economy. State level estimates of personal income showed a very small underestimation for the 1960-1980 time period. Average difference of personal income estimates from model and the Department of Commerce was 7.3 percent. This indicates the model was quite accurate for the time period checked. Underestimation at the state level was the result of the failure to capture all the economic bases of the Casper and Cheyenne major trade centers, especially trade coming from other states.

Although the input-output model invariably underestimates or overstates personal income, the adapted version does appear to "track" reasonably consistently with the Department of Commerce data. The results of the principle ex post forecasting error statistic, Theil's inequality coefficient, indicate that the adapted model predicts quite well.⁵⁶ In spite of the downward bias in the historical comparison, this evaluation does not negate the model for use in impact analysis in the two regions with major trade centers.

Analyzing the transition from historic data to corresponding model-projected values gives a good measure of model performance. Employment and

⁵⁵The mean of the average differences for the four regions is 11.3 percent.

⁵⁶The average Theil U_1 coefficients for the six regions and the state were .090 and .056 respectively. This coefficient is a summary measure, bounded to the interval of 0 and 1. A value of 0 for U_1 indicates perfect prediction, while a value of 1 corresponds to perfect inequality (i.e., between the actual and predicted values). For further discussion on the Theil coefficient, see Leuthold, Raymond M., "On the Use of Theil's Inequality Coefficients," American Journal of Agricultural Economics, Vol. 57, No. 2, 1975, pp. 344-346; and Pindyck, Robert S. and Daniel L. Rubinfeld, Econometric Models and Economic Forecasts, Second Edition, McGraw-Hill, New York, 1981.

population data were available for evaluating model performance. Employment data for historic and projected time periods were allocated to the economic sectors. The model calculates projected employment by sector, giving values to be compared to the historic employment of each sector. The 1960 to 1980 employment by sector trends compare very well with the 1981 to 2005 projection of employment by sector. Sector employment values tended to show some variations for the 1980 to 1981 period, but regional totals of the projected values were quite close to historic employment levels (Table 21, and Appendix B, Tables 61 to 66).

Considerable changes have occurred in the Wyoming economic base since 1980, including expansion in the coal and oil industries and contraction and/or closure in the uranium industry. Project files were used to incorporate these developments (shutdowns) into the model. These projects are actually baseline projects, or projects that have occurred since 1980 in addition to projected baseline economic activity. Project employment was aggregated and is shown in Table 21 as project employment, rather than being broken down by sector. The coal mining sector employment shows a drop from 3,115 in 1980 to 2,255 in 1981, but realistically, much of the project-specific employment would be in the coal mining sector. Secondary employment from construction and operational phases of the project developments was allocated to the respective sectors.

Employment growth in Region 1 from 1980 to 1981 reflects the large amount of coal mine expansion and the Wheatland electric generating facility expansion during that time period. Region 4 also shows a large increase in employment from 1980 to 1981, with the Overthrust oil and gas activity being the significant development. The large increase in employment for the region is quite reasonable for the time period. An employment decrease occurred in Region 5 as a result of the decline in uranium mining. Small changes in employment from 1980 to 1981 occurred in Regions 2, 3, and 6 indicating no

^aProject employment includes only direct employment resulting from economic development in addition to the baseline economic activity since 1980. Developments impacting Region 1 include: north, middle, and south Campbell County coal mine expansion; Campbell County uranium growth; Carbon County uranium growth; and the Wheatland II 500 MW electric generating unit. Secondary employment resulting from these projects is allocated to the appropriate sectors and included in projected employment for the respective sectors.

major developments or declines. These data indicate the model captures the economic trends quite well with respect to employment and avoids the problem of unrealistic increases or decreases in employment at the point of transition from historic to model-projected employments. Data were not available for comparing the 2005 employment projections, but the model did perform very well in the early portion of the projection period.

Population projections made by the model also give a good indication of how the model is performing. Projected populations for 1985, 1990, 1995, 2000,

and 2005 were compared to the population values from the census for 1960, 1970, and 1980 (Table 22, and Appendix B, Tables 67 to 71). Projected populations

^aBased on a birthrate of 2.1 births per female, unallocated labor pool maximum = 0.07 and minimum = 0.01, family size for construction, energy operating, nonenergy operating, indirect, and baseline is 2.291, 3.535, 3.535, 2.170, and 2.170 respectively. The maximum fraction of city workers who can work on farms is 0.2, and the maximum fraction of rural workers who can work in cities is 0.2.

^bCensus populations were unavailable, so 1960, 1970, and 1980 population estimates were based on information provided by the county agent's office.

appear to fall in line quite well with the census numbers and follow a trend compatible with the historic populations. Employment increases due to project development are reflected in population growth in Regions 1 and 4. The model performs quite well in the early years, with estimates very close to the 1980 census population.

Conclusions and Implications

The conceptualization, design, development, and application of an integrated socioeconomic impact assessment model is clearly a formidable undertaking. The value of such modeling efforts is increased to the extent that they are applicable to other settings and to the extent that they provide, through the provision of timely and accurate information, useful inputs to the decision making process. This report has attempted to address such issues by examining the adaptability and validity of one such modeling system.

In general, the results reported here suggest that the model examined is adaptable to sparsely populated rural areas and appears to provide reliable projections of economic and demographic change. In contemplating future applications of this modeling system, however, potential users should carefully examine the assumptions inherent in the model's data base. In particular, the projected baseline sales to final demand for each region of interest and the specific development projects applicable to those regions should be carefully reviewed in light of recent events. While the assumptions concerning these factors currently incorporated in the model reflect the most current information available to the authors, the dynamic nature of resource development in general and of energy markets in particular requires frequent review of assumptions concerning such activities. Should revisions in these assumptions prove desirable for some regions, the model's structure provides for easy alteration of the appropriate data files.

In summary, models like the one described here are not a substitute for detailed understanding of local conditions, trends, and associated causal forces but rather offer a mechanism for operationalizing such knowledge. Thus, they have the potential to serve as powerful and flexible tools for planners and decision makers.

APPENDIX A
PROCEDURES AND DATA SOURCES USED IN THE ECONOMIC MODULE

Essentially, the procedures and data sources used in the economic module apply to its central feature--an input-output model. This model tabulates and describes the linkages or interdependencies between various industrial groups or sectors within an economy. The input-output model assumes that the level of economic activity in a region is dependent upon its existing basic industries. These industries, which earn income from outside the region, are often termed the region's export base.

The general methods used in estimating and projecting economic activity from the NEDAM input-output model are as follows:

1. Final Demand Vectors: Data collection of sales for final demand by the region's basic economic sectors;
2. Derivation of Interdependence Coefficients: Indicates the direct, indirect, and induced requirements of the economy's sectors;
3. Estimation of Gross Business Volumes: Multiplication of final demand vectors by interdependence coefficients;
4. Productivity Ratios: Division of gross business volumes by sectoral employment;
5. Baseline Activity Projections: Historic final demand vectors and productivity ratios are projected by regression techniques with results indexed to 1980 base year dollars.

The purpose of this appendix is to discuss these various procedures and present the data sources used in adapting the NEDAM model to Wyoming. The discussion begins with an overview of the procedures used in expanding the input-output model for Wyoming. Following this, the section is divided into the various economic sectors with each containing relevant data sources and a discussion of how the final demand vectors were determined.

Input-Output Model--Interdependence Coefficients

Input-output technical and interdependence coefficients were available for southern Wyoming (Albany, Carbon, and Sweetwater counties)¹ and the Powder River Basin of northeastern Wyoming (Campbell, Converse, Crook, Johnson, Natrona, Niobrara, Sheridan, and Weston counties).² Sector delineation for the Wyoming coefficients was very different from that used for the original NEDAM model and NEDAM adaptation to Montana. Combining sectors under a broad definition, such as agriculture, oil/gas, or services, made estimating sales to final demand difficult. Although education and government sectors were broken down in great detail, they were of very little value to the model since they represent no sales for final demand. Another factor affecting the usefulness of the Wyoming coefficients was the failure to provide sectors for crops, petroleum refining, and lumber, all of which have sales for final demand. Because the effects of the input-output technical coefficients are reflected throughout the entire model, the North Dakota input-output interdependence coefficients were used for adaptation of NEDAM to Wyoming. These coefficients were checked to determine how well they represented the Wyoming economy (Table 19 of the text and Appendix B, Tables 55-60). The North Dakota interdependence coefficients were used successfully to replicate the Wyoming economy.³

³See Table 18, page 50, in Chase, Robert A., R. C. Coon, C. L. Chase, C. F. Vocke, R. J. Vuchetich, F. L. Leistritz, T. A. Hertsgaard, W. Ransom-Nelson, S. H. Murdock, P. S. Yang, and R. Sharma, Expansion and Adaptation of the North Dakota Economic-Demographic Assessment Model (NEDAM) for Montana: Technical Description, Agricultural Economics Miscellaneous Report No. 61, Department of Agricultural Economics, North Dakota Agricultural Experiment Station, North Dakota State University, Fargo, January 1983.

The input-output technical and interdependence coefficients for the North Dakota economy were derived from actual expenditures data collected in 1965 for business firms, households, and units of government in southwestern North Dakota.⁴ Energy-related sector coefficients were determined from survey data collected in 1976.⁵ Three economic sectors were added to the model for Wyoming: metal mining, lumber and associated products, and metal processing. Sector delineation and associated Standard Industrial Classification (SIC) codes are presented in Table 3 of the text.

Similarities between the economic base of North Dakota and Wyoming allowed the transfer of input-output interdependence coefficients to Wyoming. Expanding the North Dakota model (17 economic sectors) to represent the Wyoming economy (20 economic sectors) was accomplished by obtaining technical and interdependence coefficients from a recent economic analysis of northwestern Colorado.⁶ As in North Dakota, these coefficients were derived from actual expenditures data collected in 1974. Similarities between the metal mining, lumber, and metal processing industries in Wyoming and northwestern Colorado justified the use of these coefficients for Wyoming.

⁵Hertsgaard, T. A., Randal C. Coon, F. Larry Leistritz, and Norman L. Dalsted, Developing Economic Impact Projection Models for the Fort Union Coal Region, EPA-908/4-77-009, Environmental Protection Agency, Denver, Colorado, June 1977.

⁶Gray, S. L., J. R. McKean, and J. C. Weber, The Economy of Northwestern Colorado: Description and Analysis, Technical Report No. 25, Colorado Water Resources Research Institute, Colorado State University, Fort Collins, 1981.

The North Dakota input-output interdependence coefficients, originally for a 13-sector model, were calculated using the following formula:

$$([I - A]_{13 \times 13})^{-1}$$

where: $A_{13 \times 13}$ = Technical coefficients table for 13 sectors;

I = Identity matrix (a matrix consisting of all zeros with the exception of ones in the diagonal).

Survey expenditure data for the energy-related industries yielded technical coefficients for four additional economic sectors. These 17-sector interdependence coefficients were calculated as follows:

$$\left[([I - A]_{13 \times 13})^{-1} \right]^{-1} = [I - A]_{13 \times 13}$$

$$I - [I - A]_{13 \times 13} = A_{13 \times 13}$$

The original 13-sector technical coefficients table ($A_{13 \times 13}$) is expanded to $A_{13 \times 17}$ by adding zeros to the matrix.

$$[A]_{13 \times 17} + [A]_4 \times 17 = [A]_{17 \times 17}$$

where: $[A]_4 \times 17$ = Energy sectors technical coefficients table;

$[A]_{17 \times 17}$ = 17-sector technical coefficients table.

Thus, $I - [A]_{17 \times 17} = [I - A]_{17 \times 17}$

and $\left[[I - A]_{17 \times 17} \right]^{-1}$ = Interdependence coefficients for 17 sectors.

Similar methods were used to expand the North Dakota 17-sector input-output model to 20 economic sectors for Wyoming. The technical coefficients for Wyoming's 20-sector economy are presented in Table 4 of the text. Inverting the 20 X 20 technical coefficients matrix for Wyoming yielded the interdependence coefficients (Table 5 of the text).

Indexing

In order to reflect the real economic growth or decline of various sectors over time, the effects of economy-wide inflation must be controlled.

Inflation was removed from final demand vectors by utilizing a price index. The Implicit Price Index (IMP) was selected for this indexing (deflating) approach and used to calculate 1980 base dollar values. The use of the IMP as a deflator assumes that a single index was applicable for all sectors of the economy for a given year. The method is rather simple--dividing current year dollars by their respective IMP resulted in final demand vector values in 1980 base year dollars. Implicit price indices for 1960 to 1980 are presented in Appendix Table 1.⁷

Removing inflation from the final demand vectors also reflects real change in productivity ratios. Gross business volumes estimated from 1980 base final demand vectors are subsequently used in calculating productivity ratios. Thus, all economic baseline data in the economic model are expressed in terms of 1980 dollars.

Regression Techniques

Projecting final demand vectors and productivity ratios was done with regression analysis. A great number of regression analysis techniques exist to fit a projection equation (line) from the existing data. A data set can be fit with a straight line (linear regression) or with a curved line (log, quadratic, etc.). Linear regression is more acceptable for economic-demographic model projections as curvilinear regression equations often show very rapid changes in certain portions of their curves. Curvilinear regression equations tend to make projecting models act rather erratic.

The data in the Wyoming extension of NEDAM did not always yield acceptable linear regression equations (very low R^2 values) for model projections. To obtain more acceptable linear regression equations, a

⁷U.S. Department of Commerce, Survey of Current Business, U.S. Government Printing Office, Washington, D.C., various issues.

APPENDIX TABLE 1. GROSS NATIONAL PRODUCT IMPLICIT PRICE DEFLATORS FOR 1967 AND 1980 BASE

Year	GNP Implicit Price Deflators	
	1967 = 100	1980 = 100
1960	86.9	38.74
1961	87.7	39.10
1962	89.3	39.81
1963	90.7	40.44
1964	92.0	41.02
1965	94.1	41.95
1966	97.1	43.29
1967	100.0	44.58
1968	104.4	46.54
1969	109.8	48.95
1970	115.7	51.58
1971	121.4	54.12
1972	126.5	56.40
1973	133.7	59.61
1974	145.4	64.82
1975	158.8	70.80
1976	167.1	74.50
1977	176.9	78.87
1978	189.8	84.62
1979	205.9	91.80
1980	224.3	100.00

regression technique called robust regression was used. Robust regression is a technique where observations near the regression line are weighted higher than those lying a substantial distance away from the line (for a complete description of robust regression, see Leistritz, et al., North Dakota Economic-Demographic Assessment Model (NEDAM): Technical Description, 1982). In addition to robust regression, a robust regression technique with an intercept adjustment was utilized.

The three regression techniques for projecting final demand vectors and productivity ratios were determined, projections were calculated, and the three sets of numbers were incorporated into the model. The results indicated

the regression with an intercept adjustment gave more realistic overall employment projections over the entire six regions in Wyoming than the other techniques (Appendix Table 2). The 1981 projected employment was very close to

APPENDIX TABLE 2. HISTORIC EMPLOYMENT AND PROJECTED EMPLOYMENT RESULTING FROM THREE REGRESSION TECHNIQUES, BY REGION, 1980 AND 1981

Region	Historic 1980 Employment	Projected Employment					
		Regular Regression		Robust Regression		Robust Regression with Adjustment	
		1981 Employment	% Diff.	1981 Employment	% Diff.	1981 Employment ^a	% Diff.
1	32,703	25,858	- 20.9	21,985	-32.8	36,355	11.2
2	46,696	36,157	- 22.6	36,673	-21.5	46,273	- 0.9
3	64,144	406,744	534.1	42,187	-34.2	64,919	1.2
4	32,855	22,816	- 30.6	29,042	-11.6	41,086	25.1
5	23,199	19,541	- 15.8	20,330	-12.4	21,097	- 9.1
6	23,404	20,801	- 11.1	17,520	-25.1	24,015	2.6

the 1980 historic robust employment for all six Wyoming regions indicating the regression equations were predicting quite well in the early part of the projection period. Data were not available for analyzing the projections toward the end of the projection period.

Final Demand Vectors

Final demand vectors are sales for final demand by various sectors of the economy. Sectors included as final demand vectors in input-output analysis are referred to as "basic sectors" because they constitute the economic base of the area. The activities that constitute the "basic sectors" in the Wyoming economy include the production of livestock, crops, mining, lumber, and manufacturing within the area, as well as expenditures by the federal government and tourists in the area.

Final demand vectors were calculated for the period 1960 through 1980 at the regional level for Wyoming. Six economic regions were used for calculating the economic base in Wyoming (Figure 1 of the text). Basic sector final demand vectors were deflated using the IMP and projected to the year 2005 using linear regression techniques.

Data used in estimating the final demand vectors for the basic sectors in Wyoming were obtained from a wide variety of secondary sources and compiled at county and regional levels. The sources of data and methodology are described below for the basic economic sectors.

Agriculture, Livestock (Sector 1)

The agriculture, livestock final demand vector consists of total receipts from sale of livestock and livestock products. Livestock production data were published each year from 1960 to 1980 at the county level for Wyoming.⁸ State estimates of livestock income also were available for the 1960 to 1980 time period.⁹ Annual livestock sales for Wyoming were allocated to counties according to their portion of total state livestock production for each year during the time period. Wyoming's regional final demand vectors were obtained by adding livestock sales receipts for counties in each of the six regions.

Agriculture, Crops (Sector 2)

Total receipts for crops and government agricultural payments comprise the agriculture, crops final demand vector. Crop production data were

⁸Wyoming Crop and Livestock Reporting Service, Wyoming Agricultural Statistics, Wyoming Department of Agriculture cooperating with U.S. Department of Agriculture, Cheyenne, annual reports, 1961-1981.

⁹Ibid.

published annually for Wyoming at the county level for 1960 through 1980.¹⁰ Crop sales and government payments for 1960 to 1980 also were available for Wyoming.¹¹ Annual county share of state value of production for major commodities was used to allocate Wyoming's crop sales plus government payments to counties. The total crops receipts and government payments for each county in the region were added to obtain final demand vectors for each of Wyoming's six regions.

Metal Mining (Sector 3)

The metal mining final demand vector consists of value of sales of raw metals exported from the producing region. Major metals mined in Wyoming include: uranium, iron ore, and gold. Values of metals mined were available by county for each metal.¹² Metals not processed in Wyoming were assumed to be exported as a raw material. Metal processing was a small industry in Wyoming, except for the partial processing of iron ore. Because of the partial processing of iron ore before it was shipped from Wyoming, it was included in the metal processing sector. The values of metal exports were calculated, and county values were aggregated to the regional level.

Coal Mining (Sector 4)

The total receipts from sales of coal to customers located outside the region comprise the coal mining final demand vector. Production by county and value per ton were available for 1960 through 1980.¹³

¹⁰Ibid.

¹¹Ibid.

¹²Goodier, John T., D. S. Hoffman, and Helen Gilbert, Wyoming Mineral Yearbook, Mineral Division, State Department of Economic Planning and Development, Cheyenne, annual reports 1960-1981.

¹³Ibid.

Nonlocal sales of coal were assumed to be 75 percent of total production.¹⁴ County coal exports were summed to the regional level to determine Wyoming's regional coal final demand vector.

Petroleum and Natural Gas Exploration and Extraction (Sector 5)

Export sales of petroleum and natural gas from the local region constituted the final demand vector for Sector 5. Wyoming's crude oil production (in barrels) and value of production were available by county for 1960 through 1980.¹⁵ Also available were natural gas production (in million cubic feet) and value of production by county.¹⁶ The regional exports of crude oil and natural gas constituted sales for final demand. Data on exports of crude oil and natural gas from Wyoming were not readily available, but estimates were obtained from Wyoming officials.¹⁷ Three-fourths of the crude oil production in Wyoming was assumed to be exported for refining, and 85 percent of the natural gas production was exported. County petroleum and natural gas exports were aggregated to the regional level to obtain petroleum and natural gas exploration and extraction sales for final demand.

Nonmetallic Mining (Sector 6)

Total receipts from the nonlocal sales of nonmetallic minerals comprised the nonmetallic mining final demand vector. Nonmetallic mining in Wyoming included the following minerals: bentonite, trona, cement, feldspar, gypsum, lime, sand and gravel, and sulfur. County production and value of

¹⁴Goodier, John T., unpublished data, Department of Economic Planning and Development, Cheyenne, August 1982.

¹⁵Goodier, John T., 1960-1980, op. cit.

¹⁷Goodier, John T., 1982, op. cit.

production of the nonmetallic minerals was available for the years 1960 to 1980.¹⁸ Data on exports of raw ore nonmetallic minerals were not readily available; therefore, production not processed in Wyoming was assumed exported.¹⁹ All nonmetallic mineral production was assumed to be exported. County value of production was summed to the regional level to determine the nonmetallic mining final demand vector.

Contract Construction (Sector 7)

The construction industry generates sales to final demand primarily in the form of highway construction funded by federal government revenues. The amount of federal expenditures for highway construction was available only at the state level for Wyoming between 1960 and 1966.²⁰ The procedure for reporting these data changed in 1967, and actual federal expenditures for Wyoming were available at county and state level from 1967 to 1980.²¹ Federal government outlays for construction in the respective regions for 1960 to 1966 were estimated by allocating state totals on the basis of regional shares reported for 1967 to 1980.

Lumber and Associated Products (Sector 8)

Total receipts from nonlocal sales of lumber and associated products constituted the final demand vector for Sector 8. County lumber production

¹⁸Goodier, John T., 1960-1980, op. cit.

and value of Wyoming lumber production were available for 1960 to 1980.²² Approximately 95 percent of the lumber cut in Wyoming is exported out of the producing region.²³

Value of production was applied to county yield to obtain county value of production. County nonlocal sales of lumber and associated products were added to the regional level to obtain Wyoming's regional lumber and associated products final demand vector.

Agricultural Processing and Miscellaneous Manufacturing (Sector 9)

Gross output of the agricultural processing and miscellaneous manufacturing sector consists principally of the value of miscellaneous manufacturing, much of which is food processing. Also included in this sector are wholesaling activities, although they are rather small. State or county level data were not readily available for this sector. Personal income data for manufacturing and wholesale trade were available for North Dakota and Wyoming.²⁴ Values of agricultural processing and miscellaneous manufacturing

data were published at the state level for North Dakota.²⁵ The ratio of personal income for manufacturing and wholesale trade to sales for final demand for agricultural processing and miscellaneous manufacturing was calculated for North Dakota. The ratio was applied to Wyoming personal income from manufacturing and wholesale trade to calculate agricultural processing and miscellaneous manufacturing final demand vectors at the county level. Regional final demand vectors for this sector were obtained by aggregating county data.

Petroleum Refining (Sector 10)

Export sales of refined petroleum products were calculated for the petroleum refining sector. Wyoming data were available on petroleum refining capacities for 1960 to 1980.²⁶ Refineries were assumed to operate at full capacity. An average value²⁷ for each barrel of refined petroleum was determined and assigned to production to obtain total value of refined petroleum products. Data on exports of refined petroleum products from Wyoming were not readily available, but an estimate of 70 percent being sold nonlocally was used.²⁸ Regional petroleum refining final demand vectors were obtained by summing county values of refined petroleum sold nonlocally.

²⁸Goodier, John T., 1982, op. cit.

Metal Processing (Sector 11)

Sales of processed metals outside the local region constituted the metal processing final demand vector. A small amount of metal processing occurs in Wyoming. The only metal processed was iron ore, which was partially processed before being shipped out of state. Amount of iron ore processed and its processed value were available by county for 1960 through 1980.²⁹ All processed iron ore was assumed to be sold out of the processing region. County value of metal processing was determined and summed to the regional level to estimate the metal processing final demand vector.

Thermal-Electrical Generation (Sector 14)

Nonlocal sales of electricity generated by burning coal constituted the thermal-electric generating final demand vector. Locations and capacities of generating facilities were available from 1960 to 1980.³⁰ Data on total annual electricity generated at the state level also were available for that period.³¹ Total annual electricity generated was allocated to the state regions on the basis of generating capacity. Total value of electricity generated was calculated by applying the price to electricity generated.³²

Estimates of electricity exported from Wyoming were applied to regional value of production giving sales for final demand at the regional level.³³

Retail Trade (Sector 15)

The retail trade final demand vector consists of three-fourths of the dollar volume of tourism expenditures in the area. The other one-fourth is assumed to be the business and personal service final demand vector. State level tourism estimates were available for 1970 to 1980.³⁴ Wyoming's tourism expenditures were available for 1981 at the county level.³⁵ Trend estimates were obtained to backcast the 1970 value to 1960.³⁶ County share of state tourism for 1981 was used to allocate tourism expenditures in Wyoming to the individual counties for 1960 to 1980. County tourism estimates were added to the regional level and three-fourths of that value yielded the retail trade final demand vector.

Business and Personal Services (Sector 17)

The final demand vector for business and personal services is simply the remaining tourism expenditures (25 percent) after allocation to retail trade.

Households (Sector 20)

The federal government generates basic income to the household sector through payrolls and transfer payments. Federal aid to states and individuals

was published annually for Wyoming for 1960 to 1967.³⁷ Defense expenditures, veterans benefits, Old Age and Survivor's Insurance payments, Workman's Compensation, and the federal payroll also were included as basic income.³⁸ The household sector final demand vectors for Wyoming were calculated by adding total grants (less highway construction), defense expenditures (except for construction), veterans benefits, Old Age and Survivor's Insurance, Workman's Compensation, and federal payrolls.

Total federal expenditures were available on a county basis for 1967 to 1980 for Wyoming.³⁹ The final demand vector for 1967 to 1980 was calculated as follows: farm payments (included as income in Sector 2), construction outlays, and loans were subtracted from the total federal expenditures to obtain final demand vectors at county and state levels. The regional percentage of the state expenditures during the period 1967 to 1980 was used to allocate the household final demand vector to the regions for 1960 to 1966.

Employment

Wyoming's employment data were available at the state and county levels for 1960 to 1980.⁴⁰ County employment data were disaggregated to the economic

*Unincorporated municipality as reported by 1980 census data.

^aRegional growth rates were used to determine municipality populations when unavailable for calculating nonagricultural municipality allocators. Estimated 1960 and 1970 populations of Wright were 752 and 827, respectively.

^bEstimated 1960, 1970, and 1980 population based on information provided by county agent's office from each municipality's respective county.

^cRegional growth rates were used to determine municipality populations when unavailable for calculating nonagricultural municipality allocators. Estimated 1960 and 1970 populations of Midwest were 429 and 432, respectively.

^dRegional growth rates were used to determine municipality populations when unavailable for calculating nonagricultural municipality allocators. Estimated 1960 and 1970 populations of LaBarge were 161 and 164, respectively.

^eLinear interpolation was used to determine the 1970 population. Estimated 1970 population of Mountain View was 1,175.

^fRegional growth rates were used to determine municipality populations when unavailable for calculating nonagricultural municipality allocators. Estimated 1960 and 1970 populations of Jeffrey City were 486 and 552, respectively.

^gEstimated 1960, 1970, and 1980 population based on enumeration district data provided by Montana State Census Data Center; Billings, Montana.

APPENDIX TABLE 8. REGRESSION EQUATIONS^a FOR PROJECTING FINAL DEMAND VECTORS FOR THE 20-SECTOR I-O MODEL, WYOMING REGION 2, (1980 = BASE DOLLARS), THOUSAND DOLLARS

Sector	Equation
(1) Ag, Livestock	$Y = -2,730,608 + 1,422.35(X)$
(2) Ag, Crops	$Y = -119,000 + 62.10(X)$
(3) Metal Mining	$Y = 15,300.0^b$
(4) Coal Mining	$Y = -844,586 + 432.13(X)$
(5) Pet/NG Exp/Ext	$Y = -11,373,170 + 5,865.02(X)$
(6) Nonmetallic Mining	$Y = -82,941 + 42.37(X)$
(7) Construction	$Y = -11,271 + 13.13(X)$
(8) Lumber	$Y = -82,745 + 42.49(X)$
(9) Ag Proc & Misc Mfg	$Y = -3,546,140 + 1,834.82(X)$
(10) Pet Refining	$Y = -33,770,770 + 17,346.5(X)$
(11) Metal Processing	$Y = 0^c$
(12) Transportation	$Y = 0^c$
(13) Comm & Public Utilities	$Y = 0^c$
(14) Electric Generation	$Y = -3,734,626 + 1,916.04(X)$
(15) Retail	$Y = -4,935,374 + 2,540.23(X)$
(16) Fin, Ins, Real Estate	$Y = 0^c$
(17) Bus & Pers Service	$Y = -1,641,102 + 844.71(X)$
(18) Prof & Soc Service	$Y = 0^c$
(19) Government	$Y = 0^c$
(20) Households	$Y = -6,789,681 + 3,499.35(X)$

^aRobust regression with an intercept adjustment technique.

^bMetal mining final demand vector was set at a constant so the decline in the industry could be reflected with project files.

^cAn economic sector having no sales for final demand.

APPENDIX TABLE 9. REGRESSION EQUATIONS^a FOR PROJECTING FINAL DEMAND VECTORS FOR THE 20-SECTOR I-O MODEL, WYOMING REGION 3, (1980 = BASE DOLLARS), THOUSAND DOLLARS

Sector	Equation
(1) Ag, Livestock	$Y = -4,798,179 + 2,506.09(X)$
(2) Ag, Crops	$Y = 882,202 + 472.01(X)$
(3) Metal Mining	$Y = 23,500.0^b$
(4) Coal Mining	$Y = -13,185,750 + 6,729.28(X)$
(5) Pet/NG Exp/Ext	$Y = -3,493,825 + 1,827.01(X)^c$
(6) Nonmetallic Mining	$Y = -588,952 + 301.29(X)$
(7) Construction	$Y = 61,732.03 - 17.27(X)^d$
(8) Lumber	$Y = -583,943 + 299.28(X)$
(9) Ag Proc & Misc Mfg	$Y = -2,339,703 + 1,218.91(X)$
(10) Pet Refining	$Y = -26,781,540 + 13,761.5(X)$
(11) Metal Processing	$Y = 78,872.5 - 38.42(X)^e$
(12) Transportation	$Y = 0^f$
(13) Comm & Public Utilities	$Y = 0^f$
(14) Electric Generation	$Y = 33,4009$
(15) Retail	$Y = -7,041,684 + 3,624.36(X)$
(16) Fin, Ins, Real Estate	$Y = 0^f$
(17) Bus & Pers Service	$Y = -2,355,758 + 1,212.45(X)$

APPENDIX TABLE 38. REGRESSION EQUATIONS^a FOR PROJECTION OF GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR 20-SECTOR WYOMING I-O MODEL, WYOMING REGION 2, (1980 = BASE DOLLARS) THOUSAND DOLLARS

Sector	
(1) & (2) Agriculture	$Y = 14,148.58 + 7.30(X)$
(3) Metal Mining	$Y = -225.14 + 0.12(X)$
(4) Coal Mining	$Y = 126.000^b$
(5) Pet/NG Exp/Ext	$Y = -9,063.67 + 4.65(X)$
(6) Nonmetallic Mining	$Y = 16.463^c$
(7) Construction	$Y = -253.49 + 0.143(X)$
(8) Lumber	$Y = -558.47 + 0.29(X)$
(9) Ag Proc and Misc Manufacturing	$Y = 653.70 - 0.31(X)$
(10) Pet Refining	$Y = -45,401.41 + 23.29(X)$
(11) Metal Processing	$Y = 10,000^d$
(12) Transportation	$Y = -680.51 + 0.352(X)$
(13) Comm & Public Utilities	$Y = -2,028.56 + 1.051(X)$
(14) Electric Generation	$Y = -15,948.47 + 8.15(X)$
(15) Retail	$Y = -808.75 + 0.44(X)$
(16) Fin, Ins, Real Estate	$Y = -590.06 + 0.32(X)$
(17) Business & Pers Service	$Y = -32.46 + 0.025(X)$
(18) Prof & Soc Service	$Y = 14.750$
(19) Government	$Y = -444.74 + 0.23(X)$
(20) Households	$Y = 10,000^d$

^aRobust regression with intercept adjustment technique.

^bThe 1981 projected productivity ratio was used for the projection period.

^cThe 1980 productivity ratio was used for the projection period.

^dBecause very little or no employment exists in this sector for Region 2, arbitrary, very large numbers were utilized in developing projections of baseline employment.

APPENDIX TABLE 39. REGRESSION EQUATIONS^a FOR PROJECTION OF GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR 20-SECTOR WYOMING I-O MODEL, WYOMING REGION 3, (1980 = BASE DOLLARS) THOUSAND DOLLARS

Sector		
(1) & (2) Agriculture	Y = -8,702.63	+ 4.50(X)
(3) Metal Mining	Y = -311.05	+ 0.17(X)
(4) Coal Mining	Y = -6,450.38	+ 3.31(X)
(5) Pet/NG Exp/Ext	Y = 2,188.27	- 0.38(X)
(6) Nonmetallic Mining	Y = -1,858.20	+ 0.972(X)
(7) Construction	Y = -1,382.38	+ 0.722(X)
(8) Lumber	Y = -1,151.15	+ 0.59(X)
(9) Ag Proc and Misc Manufacturing	Y = -1,203.19	+ 0.64(X)
(10) Pet Refining	Y = -116,702.90	+ 59.63(X)
(11) Metal Processing	Y = -415.27	+ 0.2205(X)
(12) Transportation	Y = -797.02	+ 0.41(X)
(13) Comm & Public Utilities	Y = -2,669.15	+ 1.3808(X)
(14) Electric Generation	Y = 117.606 ^b	
(15) Retail	Y = -2,698.00	+ 1.40(X)
(16) Fin, Ins, Real Estate	Y = -633.27	+ 0.35(X)
(17) Business & Pers Service	Y = -395.89	+ 0.21(X)
(18) Prof & Soc Service	Y = -98.34	+ 0.063(X)
(19) Government	Y = -251.73	+ 0.13(X)
(20) Households	Y = 10,000 ^c	

^aRobust regression with intercept adjustment technique.

^bThe 1980 productivity ratio was used for the projection period.

^cBecause very little or no employment exists in this sector for Region 3, arbitrary, very large numbers were utilized in developing projections of baseline employment.

APPENDIX TABLE 40. REGRESSION EQUATIONS^a FOR PROJECTION OF GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR 20-SECTOR WYOMING I-O MODEL, WYOMING REGION 4, (1980 = BASE DOLLARS) THOUSAND DOLLARS

Sector	
(1) & (2) Agriculture	Y = -8,939.83 + 4.613(X)
(3) Metal Mining	Y = 10,000 ^b
(4) Coal Mining	Y = -9,187.09 + 4.69(X)
(5) Pet/NG Exp/Ext	Y = -24,031.31 + 12.38(X)
(6) Nonmetallic Mining	Y = -2,341.95 + 1.20(X)
(7) Construction	Y = -1,667.34 + 0.871(X)
(8) Lumber	Y = 25.600 ^c
(9) Ag Proc and Misc Manufacturing	Y = -3,591.98 + 1.85(X)
(10) Pet Refining	Y = -8,928.25 + 4.57(X)
(11) Metal Processing	Y = 10,000 ^b
(12) Transportation	Y = -613.63 + 0.324(X)
(13) Comm & Public Utilities	Y = -5,241.62 + 2.69(X)
(14) Electric Generation	Y = -21,006.32 + 10.72(X)
(15) Retail	Y = -2,189.04 + 1.15(X)
(16) Fin, Ins, Real Estate	Y = -4,296.10 + 2.23(X)
(17) Business & Pers Service	Y = -778.78 + 0.41(X)
(18) Prof & Soc Service	Y = -822.14 + 0.43(X)
(19) Government	Y = -934.30 + 0.4815(X)
(20) Households	Y = 10,000 ^b

^aRobust regression with intercept adjustment technique.

^bBecause very little or no employment exists in this sector for Region 4, arbitrary, very large numbers were utilized in developing projections of baseline employment.

^cThe 1981 projected productivity ratio was used for the projection period.

APPENDIX TABLE 41. REGRESSION EQUATIONS^a FOR PROJECTION OF GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR 20-SECTOR WYOMING I-O MODEL, WYOMING REGION 5, (1980 = BASE DOLLARS) THOUSAND DOLLARS

Sector	
(1) & (2) Agriculture	$Y = -6,307.47 + 3.25(X)$
(3) Metal Mining	$Y = 10.673^b$
(4) Coal Mining	$Y = 10,000^c$
(5) Pet/NG Exp/Ext	$Y = -23,520.08 + 12.09(X)$
(6) Nonmetallic Mining	$Y = -377.66 + 0.26(X)$
(7) Construction	$Y = 26.690^d$
(8) Lumber	$Y = -6,501.88 + 3.331(X)$
(9) Ag Proc and Misc Manufacturing	$Y = 43.740^d$
(10) Pet Refining	$Y = 10,000^c$
(11) Metal Processing	$Y = -310.04 + 0.175(X)$
(12) Transportation	$Y = 275.42 - 0.13(X)$
(13) Comm & Public Utilities	$Y = 299.59 - 0.12(X)$
(14) Electric Generation	$Y = 10,000^c$
(15) Retail	$Y = 891.70 - 0.42(X)$
(16) Fin, Ins, Real Estate	$Y = 62.850^d$
(17) Business & Pers Service	$Y = 20.016^b$
(18) Prof & Soc Service	$Y = 10.635^b$
(19) Government	$Y = -110.93 + 0.061(X)$
(20) Households	$Y = 10,000^c$

^aRobust regression with intercept adjustment technique.

^bThe 1980 productivity ratio was used for the projection period.

^cBecause very little or no employment exists in this sector for Region 5, arbitrary, very large numbers were utilized in developing projections of baseline employment.

^dThe 1981 projected productivity ratio was used for the projection period.

APPENDIX TABLE 42. REGRESSION EQUATIONS^a FOR PROJECTION OF GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR 20-SECTOR WYOMING I-O MODEL, WYOMING REGION 6, (1980 = BASE DOLLARS) THOUSAND DOLLARS

Sector	
(1) & (2) Agriculture	Y = -8,756.20 + 4.51(X)
(3) Metal Mining	Y = 10,000 ^b
(4) Coal Mining	Y = -4,872.84 + 2.49(X)
(5) Pet/NG Exp/Ext	Y = 735.064 ^c
(6) Nonmetallic Mining	Y = -1,277.57 + 0.66(X)
(7) Construction	Y = 894.34 - 0.43(X)
(8) Lumber	Y = -701.41 + 0.36(X)
(9) Ag Proc and Misc Manufacturing	Y = 33.265 ^c
(10) Pet Refining	Y = -18,201.25 + 9.34(X)
(11) Metal Processing	Y = 10,000 ^b
(12) Transportation	Y = -316.59 + 0.173(X)
(13) Comm & Public Utilities	Y = -2,560.52 + 1.33(X)
(14) Electric Generation	Y = 10,000 ^b
(15) Retail	Y = -2,037.36 + 1.07(X)
(16) Fin, Ins, Real Estate	Y = 270.13 - 0.10(X)
(17) Business & Pers Service	Y = -334.54 + 0.1816(X)
(18) Prof & Soc Service	Y = 24.500 ^d
(19) Government	Y = -423.77 + 0.22(X)
(20) Households	Y = 10,000 ^b

^aRobust regression with intercept adjustment technique.

^bBecause very little or no employment exists in this sector for Region 6, arbitrary, very large numbers were utilized in developing projections of baseline employment.

^cThe 1980 productivity ratio was used for the projection period.

^dThe 1981 projected productivity ratio was used for the projection period.

APPENDIX TABLE 43. REGRESSION EQUATIONS^a FOR PROJECTION OF GROSS BUSINESS VOLUME TO EMPLOYMENT (PRODUCTIVITY) RATIOS FOR 20-SECTOR WYOMING I-O MODEL, WYOMING, (1980 = BASE DOLLARS) THOUSAND DOLLARS

Sector	
(1) & (2) Agriculture	$Y = -8,618.72 + 4.45(X)$
(3) Metal Mining	$Y = 133.92 - 0.06(X)$
(4) Coal Mining	$Y = -7,225.90 + 3.70(X)$
(5) Pet/NG Exp/Ext	$Y = -12,604.97 + 6.52(X)$
(6) Nonmetallic Mining	$Y = -1,272.81 + 0.66(X)$
(7) Construction	$Y = -103.85 + 0.07(X)$
(8) Lumber	$Y = -1,104.66 + 0.57(X)$
(9) Ag Proc and Misc Manufacturing	$Y = -285.53 + 0.17(X)$
(10) Pet Refining	$Y = -51,509.23 + 26.39(X)$
(11) Metal Processing	$Y = -488.91 + 0.26(X)$
(12) Transportation	$Y = -813.83 + 0.42(X)$
(13) Comm & Public Utilities	$Y = -3,021.45 + 1.56(X)$
(14) Electric Generation	$Y = -17,259.54 + 8.82(X)$
(15) Retail	$Y = -1,925.79 + 1.01(X)$
(16) Fin, Ins, Real Estate	$Y = -1,121.36 + 0.60(X)$
(17) Business & Pers Service	$Y = -255.91 + 0.14(X)$
(18) Prof & Soc Service	$Y = 59.76 - 0.02(X)$
(19) Government	$Y = -367.16 + 0.19(X)$
(20) Households	$Y = 10,000^b$

^aRobust regression with intercept adjustment technique.

^bBecause very little or no employment exists in this sector for Wyoming, arbitrary, very large numbers were utilized in developing projections of baseline employment.

^aHistoric data indicates employment for the metal mining sector (Sector 3), but a productivity ratio could not be determined for projection purposes. Region 4 nonfuel mining final demand vector data could not be broken into metal and nonmetal components as only a very small part was metal mining. Productivity ratios are gross business volume divided by employment for each respective sector, thus, the lack of any gross business volume for metal mining would eliminate a productivity ratio. Region 4 metal mining employment would be reflected in the nonmetal mining sector (Sector 6).

^bProject employment includes only direct employment resulting from economic development in addition to baseline economic activity since 1980. Developments impacting Region 4 include: Black Butte coal mine expansion; Carbon County uranium growth; Uinta County Overthrust oil activity; Texgulf Big Island trona expansion; Tenneco trona development; and Moxa Arch gas processing plant development. Secondary employment resulting from these projects is allocated to the appropriate sectors and included in projected employment for the respective sectors.
