FALL ENROLLMENT PROJECTIONS 1976-1980 NORTH DAKOTA INSTITUTIONS OF HIGHER EDUCATION

The last five years, 1971-1975, have been a leveling off period in total postsecondary education enrollment in North Dakota. Growth of postsecondary education in the 20 years prior to 1971 can be described as phenomenal. The recent leveling off in total enrollments has included a dramatic decline in some institutional enrollments while others have stabilized or increased slightly. Accordingly, there is concern on the part of college and university administrators and legislators regarding the future structure of postsecondary education in North Dakota.

This report provides projections of fall-term enrollments at the postsecondary public and private institutions in North Dakota for 1976-1980, and analyzes factors which will influence enrollments through the year 2000. The historic data are from the Bureau of Census, the North Dakota State Health Department, the Department of Public Instruction, and the State Board of Higher Education.

Population Trends That Influence Postsecondary Enrollment

Potential postsecondary enrollments have been closely tied to the number of persons aged 18 to 22. Accordingly, the number of persons in this age group can be one indicator of the number of persons available to enroll at postsecondary educational institutions.

In the mid-1950's, the resident 18 to 22 years old age group started to increase dramatically and after leveling off in the seventies will begin a decline in 1980. These projections are based on children already born and any changes in the trend of potentially available postsecondary students will be minor. The only thing which might cause a significant change in these projections would be the unlikely event of greatly increased migration of families with postsecondary school age children. Another indicator of potential postsecondary educational enrollment closely related to population factors is the number of annual high school graduates. This is one of the indicators used in long-range enrollment projections. Since the yearly number of high school graduates is directly related to the population of 18 year olds in North Dakota, the pattern of change in number of high school graduates is similar to changes in the 18 to 22 year old population. The relationship between the leveling off of postsecondary enrollments that has occurred since 1970 and the number of high school graduates is apparent from the following:

Year	Total North Dakota High School Graduates	Total Post- secondary Enrollment
1960	8,200	12,666
1965	10,737	19,924
1970	11,608	28,571
1975	11,547	28,453

The number of high school graduates is projected to remain fairly stable through 1980. After 1980, a steady drop in the number of high school graduates is projected through at least 1990 (Table 1).¹ These projections are based on the actual number of students already enrolled in the lower grades and they are not likely to change significantly unless North Dakota experiences a significant change in migration patterns.

In order to predict the number of potential postsecondary students for periods beyond 1990, it is necessary to look at trends in the number of births to North Dakota resident mothers.

In Table 2, the data provided by the North Dakota Department of Health show that except for a short-period in 1969-1970 the number of births to

TABLE 2. NUMBER OF BIRTHS TO NORTH DAKOTA MOTHERS, BY COUNTY OF RESIDENCE, 1960 TO 1975 (CONTINUED)

€

¢`

E

¢

€

SOURCE: Vital Statistics Division, North Dakota State Department of Health.

сл

¢

North Dakota resident mothers declined from 1961 to 1973. The number of births in 1973 was 59 percent of the number born in 1961. Table 2 also includes birth data by county of the mother's residence.

Since the children born in one year will reach college age 18 years later, the above data on births and population indicate that the decline in the number of high school graduates and college age youth projected to begin after 1980 will continue well beyond 1990. Current socioeconomic trends do not indicate that the number of births in North Dakota is likely to increase significantly in the next few years.

Other Factors Influencing Postsecondary Enrollments

Although the number of persons in the traditional college age group is an important factor in determining future postsecondary enrollments, other factors must also be considered. One of these factors is the college entrance rate, i.e., the tendency of individuals to enroll in one of North Dakota's postsecondary institutions after completing their high school education.

<u>College</u> Entrance Rates

The entrance rate is a ratio measured by the number of fall-term freshmen in the 13 postsecondary institutions in North Dakota as a percentage of the number of North Dakota high school graduates of the previous spring.

42

The postsecondary entrance rate in North Dakota increased from 60 percent in 1960 to 86 percent in 1970 as shown in Table 3. Compulsory military service for young men no doubt had an influence on their decisions to enter and continue their postsecondary education. The decline in entrance

- 6 -

TABLE 3. ENTRANCE RATES TO POSTSECONDARY EDUCATION IN NORTH DAKOTA. POSTSECONDARY FRESHMEN FALL ENROLLMENT AS A PERCENT OF THE NUMBER OF PERSONS GRADUATING FROM HIGH SCHOOL IN THE PERVIOUS SPRING, 1960-1975

1960 = 60.20%	1968 = 82.70%
1961 = 63.94%	1969 = 84.57%
1962 = 66.23%	1970 = 86.19%
1963 = 65.37%	1971 = 83.28%
1964 = 73.85%	1972 = 80.34%
1965 = 79.16%	1973 = 79.33%
1966 = 79.27%	1974 = 77.72%
1966 = 79.27%	1974 = 77.72%
1967 = 80.84%	1975 = 85.90%

rates from 1971 to 1974, after termination of the military draft, tends to support this view. Since 1974 the entrance rate increased to its previous level.

The cause of the increase in the 1960's then the decline and subsequent increase during the 1970's involves a complex mix of factors. In addition to the military consideration during the 1960's and 1970's, there are other factors which contribute positively to high school graduates' decisions to continue their education. Some of these decisions are: increasing levels of family income, higher levels of scholastic ability, improved transportation to centers of educational institutions, increasing levels of parental education, decreasing employment opportunities for those with only a high school education, and others. The reverse of the above situations contributes negatively to decisions to enter postsecondary education. Although precise relationships among these factors are not known, some general patterns are evident.

A number of high school graduates going on to postsecondary education will attend the institution most accessible to their home, particularly if their educational plans are not clear when their decisions must be made. Also, many students choose among institutions on the basis of cost, including the cost of living away from home. College entrance tests which measure high school achievement and potential scholastic performance may influence decisions to enter postsecondary institutions. Such tests also will influence the choice of institution.

A scientific and technologically oriented society requiring skills and academic education beyond high school has made higher education a bargain purchase. Growth of service industries and salary increases have provided increased opportunities and incentives for those with a vocational education and have influenced decisions as to which institution to attend. These decisions are reflected in the growth patterns of North Dakota postsecondary institutions.

At this time, approximately 8 out of 10 high school graduates continue their education but seek different types of educational opportunities in different places.

Retention Rates

A significant determinant of institutional enrollments is the rate of persistence to graduation of those who enter as freshmen. Some students take more time than others to complete their course of study, some graduate on schedule, and some drop out.

The reasons for continuing advanced learning are much the same as those which lead students to enter as freshmen. Institutional environment, employment opportunities, marriage, or transfers to other institutions influence decisions to drop out. However, transfers to other institutions in the state retains the student within the North Dakota postsecondary system.

منا

For the purposes of this report, the most recent retention rates for each class in each institution were used for the annual estimates of enrollments through 1980. For the short-term this appears reasonable. However, long-term projections on this basis become more unreliable as the time horizon is extended. Future interactions among the variables determining

- 8 -

retention rates--e.g., student socioeconomic characteristics, program changes, state and federal policy, tuition reciprocity among states, etc.,-surely will be reflected in the number of students retained, as well as the numbers entering postsecondary education.

Total Postsecondary Enrollments

Distribution of students among types of institutions and actual enrollments from 1970 through 1975 and estimates for 1976 through 1980 for each of the 13 postsecondary institutions in North Dakota are shown in Tables 4 through 17 and summarized in Table 18.

The combination of numbers of high school graduates, entrance rates, and retention rates determines the total enrollment in postsecondary educational institutions. The enrollment increases in North Dakota institutions from 1960 to 1970 were the result of increases in entrance rates and increased retention rates.

Since 1970 the number of entrants into some of the four-year state colleges and retention rates therein have declined. The nationwide decline in demand for elementary teachers resulting from a decline in the number of births since 1961 induced a number of potential four-year college students to change their choice of institutions.

Total enrollments in the two-year institutions continued to increase in the 1970's but at a lesser rate than prior to 1970. The demand for technicians of various kinds, together with higher wages and the desire of people to pursue a technical career in contrast to an academically or professionally oriented career, continued to attract high school graduates. In the aggregate, the two-year institutions grew at a faster rate than the other public state institutions.

One of the two private four-year colleges (Mary College) grew at a faster rate than all other postsecondary institutions. Although the absolute growth at the two universities was the largest by type of institution, the rate of growth was less than for the two-year institutions.

At this time it seems that enrollments in the aggregate will increase slightly between 1976 and 1980. This will include growth at the two universities and the two-year schools and minor declines at the public four-year colleges. Altogether, a period of more stability than in the first half of the 1970's.

However, after 1980 enrollments will begin a population induced decline that will continue into the 1990's.

377

Long-Term Population Changes

An earlier study at North Dakota State University² provides baseline population projections by age and sex for five-year periods from 1975 to 2000 for North Dakota. The projections involve systematically changing patterns of births, deaths, and migration, and projects such changing patterns to a given period in the future. The above study is provided as an appendix in this report.

The projections should be seen as a portrayal of what would occur in North Dakota if population processes follow basic patterns not affected by large-scale developments.

When making long-term projections of population and enrollments, assumptions must be made regarding mortality, births, and migration. For the purpose of this report current mortality rates were assumed to continue stable over the projection period. The fertility level assumed to be most

- 17 -

²Population Projections by Age and Sex, 1975-2000, State of North Dakota, Agricultural Economics Statistical Series, Issue No. 31, Department of Agricultural Economics, North Dakota Agricultural Experiment Station, North Dakota State University, Fargo, August, 1976.

likely to prevail was 2.1 children per adult female (population replacement fertility level). Three migration rates were used to provide a range of possibilities that are likely to contain the correct population from which enrollments will be drawn. The three alternative assumptions are: (1) that the patterns of heavy net out-migration of 1960-1970 will continue, (2) that net migration will be reduced to one-half of the 1960-1970 rate, or (3) that net out-migration will not continue and all persons will remain in the state or be replaced by equal numbers of in-migrants (zero migration).

The assumptions described above were used as a basis for estimating the number of 18-22 year olds that would be potential entrants into postsecondary education and are shown in Figure 1.

The data in Table 19 provide estimates of total postsecondary enrollment in all North Dakota institutions from 1980 to 2000 on the basis of population projections of 18 to 22 year olds at alternative migration rates and replacement level fertility rates.

140

ر اغا

Estimates of enrollment distribution by type of institution based on zero migration levels are shown in Table 20. This would be the largest number that could be expected on the basis of replacement fertility levels and no net migration.

Projected changes in the number of college age youth will affect enrollments in North Dakota postsecondary institutions to the extent that this traditional age group accounts for the enrollment in each institution. Since the vast majority of students are drawn from this traditional pool of 18 to 22 year olds, the projected enrollments will tend to follow closely the trends in population of this age group.

These projections are based on statewide assumptions. Future enrollment patterns in individual institutions will be influenced by factors which are not reflected in statewide trends. Such factors include development of new programs or phasing out of existing programs on individual

campuses, financial conditions affecting individual institutions, or regional differences in population growth or decline.

Long-range projections indicate that the period of rapid and sustained growth in postsecondary enrollments has ended. If these projections are reasonably accurate, postsecondary enrollments will be at a fairly constant level through 1980.

If the steady drop in enrollments predicted to begin in 1980 continues into the 1990's as the data on birth rates seem to suggest, postsecondary institutions will be faced with administrative and program adjustments. Careful planning will be needed at the state and institutional level to meet the challenge of shifting from a period of rapid expansion to a period of gradual to rapid contraction. The comparative stability projected for 1976 to 1980 will provide a "breathing spell" and time to plan for the enrollment decline.

POPULATION PROJECTIONS by Age and Sex, 1975-2000 for North Dakota

STEVE H. MURDOCK¹ AND THOMAS K. OSTENSON²

INTRODUCTION

This report is the ninth in a series of reports presenting baseline population projections by age and sex for five year periods from 1975-2000 for North Dakota. Each of the eight preceding reports presents data for a single state planning region and its component counties. The present report presents projections for the total state.

As noted above, the projections presented are baseline projections. Thus, they involve systematically changing patterns of past population processes and projecting such changed patterns to a given period in the future. They do not take into account rapid developments, such as may occur due to energy development, in western North Dakota. Therefore, the projections presented in this report should be seen as portraying what would occur in the state if population processes were to follow basic patterns not affected by large-scale developments.

In addition, in using such projections it is important to recognize that any set of projections is based on a set of assumptions about the patterns that basic population processes, such as migration, mortality, and

^IAssistant Professor, Department of Sociology and Anthropology, College of Humanities and Social Sciences, North Dakota State University, Fargo, North Dakota.

²Associate Professor, Agricultural Economics Department, North Dakota Agricultural Experiment Station, North Dakota State University, Fargo, North Dakota.

fertility, will take during the projection period. The projections based on these assumptions will be correct only if the assumptions are correct. The accuracy of projections then are determined by the accuracy of the assumptions on which they are based.

Finally, studies of the accuracy of such projections (Barclay, 1958; Shryock and Siegel, 1973) indicate that projections tend to be less accurate for areas with small population size, for areas where rapid social and economic changes are occuring, for areas with histories of population decline, and for longer periods of time. Many of these factors obviously apply to many North Dakota counties and to projections for a period including the year 2000.

Accordingly, numerous factors suggest that any set of projections should be used with caution. If so used, however, they can provide essential information for numerous persons charged with making short-term and long-term plans for North Dakota residents.

ريعا

General Projection Methodology

The population projections presented here were completed through the use of the Cohort-Survival method of population projection. This method consisted of applying various assumptions concerning the processes of migration, mortality, and fertility to specific five-year age-sex cohorts. Given such assumptions, projections for future periods were made through the use of the basic population equation of:

 $P_2 = P_1 + B - D + M$ Where: $P_2 = Populations at a given future time$ $P_1 = Populations at a given base period$ $B = Births between P_1 and P_2$ $D - Deaths between P_1 and P_2$ $M = Net Migration between P_1 and P_2$

- 26 -

In the present study the base period used was 1970. This base period was used because it is the latest period for which accurate data are available from the U.S. Census.

Projected population by five-year intervals were arrived at as follows:

- The number of persons remaining in each age-sex cohort, at the end of each five-year period, was determined by applying a series of projected migration and mortality rates to the number in that age-sex cohort in the preceding five-year period.
- The number of births occurring during the projection period was determined by applying a series of projected fertility rates to the number of women in the child bearing age groups.
- Populations under each series of assumptions were then aggregated across appropriate age-sex groups to obtain a series of projected populations for each county.
- County totals were aggregated to obtain total projected populations for the state.

Assumptions

The rates of migration, mortality, and fertility used in the procedures outlined above were as follows:

Migration

Age-sex specific migration rates for North Dakota counties for 1960-70 were taken from <u>Net Migration of the Population</u>, <u>1960-70</u>, <u>by Age</u>, <u>Sex</u>, <u>and</u> <u>Color</u> by Gladys Bowles, Calvin L. Beale, and Everett S. Lee, Economic Research Service, USDA, Institute for Behavioral Research and Research Applied to National Needs, Athens, Georgia: University of Georgia Printing Department, 1975. For migration three alternative assumptions were made on the basis of such data. These were:

- That the 1960-70 migration rates will continue throughout the projection period.
- That the level of migration over the projection period will be one-half of the 1960-70 level.
- 3. That there will be no migration into or out of the area over the projection period. (That the migration rate will be zero).

These assumptions provide a range of possibilities that the authors believe are likely to contain the correct future population for the state. For most counties the past patterns have been ones of heavy out-migration. Thus, the three alternative assumptions mean that (1) patterns of heavy out-migration will continue, or (2) that they will be greatly reduced (one-half), or (3) that out-migration will not continue and all persons will be retained within the state or be replaced by equal numbers of inmigrants.

Mortality

For mortality, survival rates were computed from life tables from <u>North Dakota Abridged Life Tables</u>, <u>1960-70</u> by Richard Ludtke and Richard Blair, Division of Health Statistics, North Dakota State Department of Health, 1974.

فغنا

Given the low level of mortality already attained in the state, these rates were assumed to remain stable over the projection period and were used in all projections for all counties.

Series <u>Migration</u>	Fertility	Mortality
I 1960-70 Rate II 1960-70 Rate III 1960-70 Rate IV 1/2 1960-70 Rate V 1/2 1960-70 Rate VI 1/2 1960-70 Rate VI 1/2 1960-70 Rate VI 1/2 1960-70 Rate VI 1/2 1960-70 Rate VII Zero Migration VIII Zero Migration IX Zero Migration	1.8 Births Per Female 2.1 Births Per Female 2.5 Births Per Female 1.8 Births Per Female 2.1 Births Per Female 2.5 Births Per Female 1.8 Births Per Female 2.1 Births Per Female 2.5 Births Per Female	1960-70 Survival Rates 1960-70 Survival Rates

These series present low, medium, and high projected populations. Series I, II, and III present projections of general population decline with relatively high (in most cases out) net migration rates. Of the three series (I, II, and III), Series I presents the lowest population projections with high migration rates being combined with low fertility rates. Series IV, V, and VI are intermediate projection series with migration rates lower than in Series I, II, and III, but higher than those for Series, VII, VIII, and IX. Series VII, VIII, and IX generally present the highest projected populations with the levels of migration reduced to zero. Of Series VII, VIII, and IX, Series IX with a fertility assumption of 2.5 births per adult female yields the highest population projection of any series.

Use of Projections

The nine series of projections presented in this report show a wide range of population size alternatives. These alternative projections are presented in order to provide a widely flexible data base for users. In addition, each series illustrates a population base that may exist in the state in the future if various sets of circumstances affecting the economy of the state were to occur.

Series I, II, and III represent alternatives portraying continued population decline in the state. They thus indicate a perpetuation of past economic trends. The migration rates utilized in these series are those

Fertility

Age-specific fertility rates were computed from births by age of mother for 1972, 1973, and 1974. These data were obtained from the Division of Health Statistics, North Dakota State Department of Health.

Three alternative assumptions were used for the process of fertility. These assumptions were as follows:

- That the fertility level will be such as to result in a lifetime fertility rate of 2.5 children per adult female.
- 2. That the fertility level will be such as to result in a lifetime fertility rate of 2.1 children per adult female (population replacement fertility level).
- 3. That the fertility level will be such as to result in a lifetime fertility rate of 1.8 children per adult female.

Each of the sets of assumed rates noted above was projected over time in accordance with the procedures delineated by Tarver and Black (1966). The national data used in conjunction with these techniques were from the following publications:

<u>Projections of the Population of the United States by Age and Sex:</u> <u>1972 to 2000</u>, Current Population Reports P-25 No. 493, U.S. Department of Commerce, U.S. Government Printing Office, Washington, D.C. December, 1972.

<u>Projections of the Population of the United States, by Age and Sex:</u> <u>1975 to 2000, With Extension of Total Population to 2025, Current</u> Population Reports P-25 No. 541. U.S. Department of Commerce, U.S Government Printing Office, Washington, D.C., February, 1975.

Projection Series

Alternative rates for each demographic process as delineated above were combined to form nine alternative projection series. The series so formed are as follows: which occurred in the past decade and are in most cases rates of heavy out-migration. The three fertility assumptions are used because fertility, although historically quite high, has been declining rapidly in recent years. Thus, for users who wish to ascertain what the continuation of past population processes would mean for the state, Series I, II, and III should serve as useful guides.

Series IV, V, and VI represent intermediate population projections. They indicate some alteration of past economic trends which would reduce the level of heavy out-migration that has occurred in the past. Again, three alternative fertility assumptions have been used to reflect the declining rate of fertility. Among these series, Series V represents the middle series of all nine series. As such, its use might be recommended for those who wish to use a series that indicates some changes from past patterns but not the more extreme changes shown in Series VII, VIII, and IX.

Series VII, VIII, and IX present the largest population size alternatives. These projections assume that basic economic and employment trends will be such that all persons born in the state can stay in the state or that equal numbers of new residents will replace those who out-migrate (Zero outmigration). These series allow one to address the question of what the future population in the state would be if the appropriate economic base was available to support all those born in the state. These series again use several alternative fertility assumptions reflecting various levels of possible fertility in the state.

In sum, the nine projection series presented here offer a look at alternative state futures in terms of population size. As such, they represent an attempt to foresee what may occur in the state in the next quarter.

- 31 -

century. Although such attempts are invariably destined to be incorrect in some respects, it is hoped that the inclusive information in these projections will provide useful data for planning efforts at the county, regional, and state level.
