Market structure and coherence of international cooperation: the case of the dairy sector in Malawi

Abstract

A supply chain in disarray can be identified not only as a barrier to growth for the agricultural sector but also as one to achieving food security in a country because it may lead to either a deficiency in food production and/or too high prices. Using the dairy sector of Malawi as an example, the purpose of this paper is to discuss the coherence between market structure and the development strategy pursued by international donors via. Within Malawi the dairy sector may be characterised as a segmented market: with both formal and informal milk markets, with smallholder producers serving both markets. The formal market includes a reducing number of processing firms operating with idle capacity and selling dairy products to an affluent segment of the urban population, whilst the informal market comprises the sale of unprocessed milk products to the less affluent urban population and also rural areas. In this context, cooperative international action, conducted through agencies from a range of countries, is targeted at improving the efficiency of the formal supply chain and also the creation of local supply chains that sell processed products directly to poor consumers. The paper discusses reasons why these two cooperation strategies, given the structure of the sector, may potentially conflict with each other, the need to address the degree of market imperfection of the formal sector and the desirability of ex-ante coordination of plans amongst donors.

Keywords: Malawi dairy supply chain, development economics, industrial organisation.

JEL codes: O, L.

I. Introduction

Supply chains in disarray have been identified in the economic literature as a barrier to growth for the agricultural sector (e.g., Gorton and White, 2007) and they can also be a constraint to the achievement of food security in a country because less than the optimal amount will be produced with a given level of resources (therefore, affecting the availability of food) and at higher prices (worsening accessibility and affordability of food).

Reasons behind the malfunctioning of supply chains are various and in many cases are path dependant as in the case of industries born from import substitution experiences (e.g., see Baer, 1972 for a review of the Latin American case and Mytelka, 1989, for the African case) or the corollary of those emerging from structural reforms such as in the case of the transition economies (e.g., Gow and Swinnen, 1998; Gorton et al, 2006). The consequence of these changes include, amongst others, supply chains that are plagued with problems of inefficiency, high transaction costs, unbalanced power distribution along the marketing chain leading to important welfare implications for each of the supply chain participants. Cooperation from international donors can help improve the situation of the aforementioned supply chains through a number of ways including identification of problems (e.g., value chain analyses), knowledge transfer that aids innovation and the innovations, the provision of credit for different supply chain stakeholder.

The purpose of this paper is to discuss the coherence between the market structure of a productive sector or supply chain and the cooperation received from multiple donors, particularly when the latter is not coordinated. In that case, the efforts from multiple donors can pull the sector in different directions either neutralising the progress of the sector or slowing it down. The dairy sector of Malawi is chosen to highlight these issues.

The Malawian dairy sector is an interesting case to study, because although it is a small country, it has characteristics that can be found in the dairy sectors several of the Sub-Saharan African countries (e.g., Kurwijila and Bennett, 2011) such as: the presence of smallholding production; the existence of a formal supply chain that markets processed products (e.g., pasteurised milk) and an informal sector that markets unprocessed products directly to poor consumers and; a processing sector (part of the formal supply chain) with significant idle capacity. In addition, Malawi has the lowest per-capita consumption of milk in Africa, estimated at 4.7 kg/capita/year compared to an African average of 15 kg/capita/year (Imani Development Consultants, 2004, CYE Consult, 2009). In this context, different international donors, in apparently uncoordinated efforts, cooperate with the country, by both, improving the formal supply chain through knowledge transfer, the supply of micro credit etc. and also by donating capital goods to dairy producer cooperatives in order to create local supply chains that can serve consumers directly with pasteurised milk instead of selling the milk to processors.

This paper discusses why, given the structure of the formal dairy sector, the two aforementioned cooperation strategies are actually conflicting and ex-ante coordination of plans amongst donors would be desirable. Furthermore, key to the choice of the desirable strategy to follow (i.e., strengthen the formal sector or foster local supply chains) is whether the formal sector operates under perfect competition. Thus, on the one hand, if the sector is not perfectly competitive, then efforts aimed at strengthening the different stages of the formal supply chain (such as improving the efficiency of farmers) might fail in the longer run due to a lack of incentives (e.g., Alston et al., 1997). Under this situation, the strategy of creating local dairy supply chains might be appropriate in order to “discipline” the formal sector, forcing it to expand the production of processed milk, reduce the dairy product prices and increase the demand for milk. On the other hand, if the formal sector is competitive but inefficient, the strategy of creating short dairy chains worsens the situation by further reducing the amount of milk available to processors increasing their idle capacity and average costs.

The paper begins by providing an overview of the Malawian dairy sector from production to consumption. Next, a description of the cooperation work undertaken by major donors in Malawi is presented. The efficacy of the two cooperation strategies are discussed in the next section, including the use of estimates of the degree of imperfect competition, which are based on information collected from several value chain analyses carried out for the sector. Finally, conclusions are presented.

II. The dairy sector in Malawi

The purpose of this section is to present an overview of the structure of the Malawian dairy sector. This is based on secondary information collected as part of several value chain analyses carried out as part of the assessment required by international donors.

Historical background

Market-oriented milk production started in Malawi as a result of an increasing demand for liquid milk in the southern region of Malawi, mostly around the major towns of Blantyre and Zomba (see Figure 1). This development led a group of farmers to import high-yielding dairy cattle from South Africa and Zimbabwe. Thus, for instance, between 1952 and 1954 more than 54 exotic dairy cattle were imported into the country and the commercial farms marketed milk directly to consumers. The first milk plant to pasteurise and market fresh milk in Malawi started operation in 1961 (Munthali et al., 1993, Chagunda, 2009).

Figure 1: Malawi map

Source: Buck (2008).

Intensive smallholder dairy production in Malawi only began in 1969 under a government initiative with the assistance of the Food and Agriculture Organization of

the United Nations (FAO). The Malawian Government organised farmers into milk bulking groups¹ to operate as collection and checking centres, and established, through the Malawi Milk Marketing project, processing plants which were installed in the three major cities: Blantyre (1969), Lilongwe (1973) and Mzuzu (1974). In 1985, under a structural adjustment programme, the Malawi Milk Marketing project was reorganised and a statutory body, the Malawi Dairy Industries, took over the existing three dairy plants and three dairy farms and was given the mandate to operate commercially (Imani Development Consultants, 2004).

In 1997, Malawi Dairy Industries were privatized. As a result, three private dairy processing companies were established in each region of Malawi: Dairibord (Blantyre), New Capital Dairy (Lilongwe), and Northern Dairy Industries (Mzuzu). In addition, two new private investors, Suncrest Creameries (Blantyre) and Lilongwe Dairy (Lilongwe) began dairy operations in 1998 and 2001, respectively.

The supply of milk

In Malawi, dairy production is performed on both smallholder and large-scale dairy farms. The major differentiating features of these two dairy sub-sectors are the holding size, the genotype of cattle raised, and the level of management applied.

The smallholder dairy sector is the largest subsector in the Malawian dairy industry, accounting for about 49,193 tonnes of milk in 2008, which is approximately 80 per cent of the total milk production (Chagunda et al., 2006, DAHLD, 2008). Furthermore, the Government considers dairy production a priority within the livestock sector through a 5 year Heifer programme (Malawi Government, 2008).

According to CYE Consult (2009) it has been estimated that 80 per cent of the milk marketed in Malawi is produced in the Southern Region, 15 per cent in the Central Region and 5 per cent in the North Region. The production in the Southern Region has become more developed because land holdings are smaller than other parts of the country and dairy production offers a higher return per unit of land compared to other alternative options. Furthermore, dairy farmers with a small land area can make use of their crop residues, grass grown on uncultivated waste land and dambos (i.e., shallow wetlands) that are unused for crop production. Moreover, the Shire Highlands area (a plateau in southern Malawi, located east of the Shire River) are particularly suitable for dairy production because of its close proximity to Blantyre, the existence of good feed resources, a favourable climate and being relatively free of livestock diseases. The area has well developed milk collection network served by a reasonable road network system. There are other favourable milk producing areas in the country such as the Viphya Plateaus (south of Mzuzu, Northern Region) or the Misuku Hills (Northern Region), but they suffer from isolation from any large urban areas, and are served with a poor road infrastructure system.

Non-governmental organizations (NGOs) such as Land O' Lakes with funding from USAID Small-scale Livestock Promotion Program, World Vision Malawi and Asian Rural-Urban Development and Peace Institute (ARDEP) have incorporated dairy development in their rural programs. This has resulted in increased numbers of

¹ Milk bulking groups are operated by farmers' associations.

improved dairy animals. The predominant genotype on the large-scale dairy farms is the Holstein Friesian although some of these farms also have a few Jersey cows and other dairy breeds.

Despite the work done to improve the supply of milk as shown in Figure 2, based on FAO data, the domestic production response has been unimpressive showing an increasing trend between 1961 and 1987 but then followed by ongoing instability since then, with periods of rapid production growth (though not reaching the peak of 1987) followed by dramatic decreases.

Figure 2 - Malawi: Production of milk 1961-2008 (tonnes)

Source: FAO

The marketing of milk

It should be noted that only a relatively small percentage of the milk produced domestically is destined to formal channels (i.e., the total milk undergoing pasteurisation) through the milk bulking groups.

According to CYE Consult (2009) milk collection first started near to Blantyre in the Shire Highlands and milk is now collected from a radius of 80 kilometres from the city. The Shire Highlands Milk Producers Association (SHMPA) in the Southern Region has 22 different milk bulking groups who on average (depending on the season), supply between 14,000 to 19,000 litres of milk daily to dairies in Blantyre and Lilongwe. Surrounding Lilongwe, there are 18 milk bulking groups who form the Central Region Milk Producers Associations (CREMPA), but CYE Consult estimated that only 10 were fully operational at the time of their study. Around Mzuzu, the Mpoto Dairy Farmers has 9 milk bulking groups.

Chitika (2008) estimated that about 19 per cent of the milk produced was consumed on farm or wasted and the remaining 81 per cent marketed either to the formal sector through milk bulking groups (57 per cent) or sold to vendors in the informal market (23 per cent). These percentages differ significantly from those produced by Imani Development Consultants (2004) who estimated that in 2004 the 6,500 tonnes of milk reached the formal sector (16 per cent of total milk supplies, including imports) and

27,000 tons or 50 per cent of total milk supply, including imports were destined to the informal market.²

According to Chitika (2008) the difference between his figures and those presented by Imani Development Consultants could be attributed to recent technical and financial support from organizations like Land O'Lakes and the Small Scale Livestock Promotion Programme (SSLPP) in selected milk bulking groups, who as a condition of this support prohibited farmers from supplying the informal market. If they did so they were at risk of losing their animals. This restriction only applied to farmers who accessed dairy animals from these organizations.

Chitika (2008) also explored the reasons why farmers were involved in the formal and informal markets. He argued that farmers sold milk in the formal market due to the fact that it assured market consistency and also smoothed consumption patterns. This is due to the fact that payments in the formal market are monthly, which acted as a form of savings mechanism in comparison to instant payments received in the informal channel. Three main reasons were given for the use of the informal market: higher prices than in the formal market³; access to cash quickly (through instant payment) and; low risk of non-sale, since no tests for milk quality were conducted.

The existence of a difference in the price received by farmers in the formal and informal market is an interesting feature of the milk market in Malawi. Imani Development Consultants (2004) estimated that the production cost for a litre of milk was between 14-16 MK/litre as at March 2004⁴ for an average smallholder in the Southern Region. This cost of production, however, varies across different livestock management systems (e.g., smallholder versus estate) and between smallholders. The price paid in the informal sector was around 20 MK/litre in the village when sold to institutional buyers. The base price for un-chilled milk paid by the milk bulking groups varied from 19 to 22 MK/litre.

According to Chitika (2008) based on information from around 2007, the price offered in the formal channel was uniform, while that of the informal channel varied in different locations. Overall, the milk price per litre in the informal market ranged from MK 40 to MK 80 with a mean of MK just under MK 61. In the formal market the price was MK 44 per litre.

Processing of dairy products

The processing sector in Malawi currently comprises four firms (according to CYE Consultants (2009) the processor New Capital Dairy has ceased operation). Table 1 presents data that combines information from Imani Development Consultants (2004) and CYE Consult (2009), who undertook a value chain analysis of several Malawian chains, including dairy, for the European Commission.

² It is important to note that milk that is rejected from the formal channel is sold to vendors in the informal market. According to Chimbaza (2010) a high percentage of the milk sent to the formal channel is rejected due to quality (estimated at 17 per cent).

³ The higher price received in the informal market than in the formal market was also reported by Barnard (2007).

⁴ The exchange rate in 2004 was 1 US\$=108 Malawian Kwacha (MK).

Table 1: Production Capacity and Utilization Major Dairy Processors

Company	Location	Production Capacity 1/ Thou. lt/day	Production Utilization 1/ Thou. lt/day	Idle capacity (%)	Main Dairy Products	Market share 2/ (%)
Dairibord	Blantyre	40	12-13	30-33	Pasteurized Milk, Flavoured Yoghurt and Chambiko	70
Suncrest	Blantyre	25	8-10	33-40	Pasteurized and Steri Milk, Drinking, Yoghurt	15
New Capital Dairy	Lilongwe	32	3-4	9-13	Pasteurized Milk, Yoghurt, Chambiko, Ice Cream	0
Lilongwe Dairies	Lilongwe	20	7	35	Pasteurized Milk, (Flavoured) Yoghurts	10

Notes

1/ Information from Imani development consultants (2004) but cited as valid by CYE Consult (2009).

2/ Ceased operation. Shares around 2008.

Table 1 shows that processing firms operate on average at about 30 per cent of their capacity.⁵ This percentage though does appear to fluctuate as Imani Development Consultants (2004) indicate a range of between 20 to 40 per cent of their capacity. This view that there is marked overcapacity is supported by Fintrac (2008) who point out that Malawi's two largest dairy plants, Dairibord Malawi and Lilongwe Dairies, are operating under capacity, by 42 percent and 50 percent, respectively. It should be noted that available measures relate to idle capacity in an engineering sense rather than, economic capacity which is determined by the optimal use of the resources, given input and output prices (see Winston, 1974 for a discussion of this issue).⁶

An interesting feature of the processing sector, not uncommon in Africa, is that part of the milk that it is domestically transformed into processed products is actually imported milk powder, which has been reconstituted (Fintrac Inc., 2008). The amount of milk powder that it is imported varies from year to year, although according to Fintrac Inc. it is approximately 2,000 MT per year.⁷

Imani Development Consultants (2004) reported that, circa 2003, processors paid the milk bulking groups around 20 to 22 MK per litre but they noted that the price varied

⁵ Excess capacity is commonplace in African manufacturing being repeatedly mentioned in the development economics literature (e.g., Mytelka, 1989 and Mazumdar and Mazaheri, 2003 for several Sub-Sahara African countries).

⁶ According to CYE Consultant (2008) a lot of the machinery used by the processors is out of date and needs replacing. This is especially true with Northern Dairies where some of the processing machinery is over fifty years old.

⁷ According to Fintrac Inc. (2009) Malawi imports all of its milk powder requirements, averaging about 2,000 MT per year over the past five years, the equivalent of 15.3 million litres of whole milk. The 2007 import data showed a steep decline to 1,384 MT, attributed to the unprecedented price increases for milk powder, which in the case of the EU price of whole milk powder peaked in September 2007 at US\$5,500 per MT.

according to such factors as the volume collected, distance to the factory and a bonus system for the milk bulking groups etc. During the same period, imported milk powder was landed in Malawi at a price of 27 MK per litre (reconstituted) (i.e., at least 30 per cent more expensive than domestically collected milk⁸). Liquid pasteurised milk was sold to retailers at around MK 50 per litre and to the final consumer at around MK 60 to 62 per litre.

Little information is available on the actual processing costs of milk in Malawi. According to Imani Development Consultants (2004) these vary by product and generally, the less the value added the less the processing cost. The margin is also related to the added value. According to the processors, the net margin on liquid pasteurised milk is as low as 5 per cent whereas this can be as high as 15 per cent for products which have higher added value such as cheese. For these products a much higher gross margin was reported but due to high operational costs, especially electricity, water and transport costs within Malawi, the net margin is estimated at between 3 to 10 per cent. Supermarkets are reported to take a margin of 15 to 20 per cent. According to Imani Development Consultants the processing sector attains profits despite its high costs by targeting the affluent part of the urban population.

Information from CYE Consultant (2009) reported that in 2008 the prices being offered for fresh milk by the main processors had improved. Suncrest Dairies in Blantyre paid producers MK 52 per litre and Lilongwe Dairies bought milk in the Central and Southern Regions at MK 55 per litre, while the Blantyre based Dairibord also increased its own price to MK 55 per litre. However, because there was little competition in the Northern Region for processed milk, Northern Dairies paid only MK 40 per litre. Untreated and often diluted milk is sold by vendors directly to consumers at about MK 50 per litre. Consumers are paying in supermarkets between MK 70 to 100 per litre for pasteurised milk.

Trade in dairy products

CYE Consultant (2009) report that due to low internal demand, value added products such as cheese, yoghurt and butter are imported to satisfy the demand that exists. However, whole dried milk (i.e., milk powder) and UHT milk are by far the major imported products in the dairy sector. Figure 3 presents the imports of whole dried milk.

On a milk-equivalent-basis imports have a dominant role in the market and exceed the formal local market supply by a substantial margin (75 per cent versus 25 per cent circa 2008) even though imported milk is more expensive than locally produced. The source of imported milk products depends very much on world prices and also on which part of the world is generating surpluses. At present cheese and yoghurts are coming from South Africa, butter from Zimbabwe and powdered milk from Ireland and New Zealand.

⁸ Note, however, that the powder milk avoids costs in terms of quality and other marketing costs associated with the milk collection.

Figure 3 - Malawi: Imports of whole dried milk 1988-2008 (tonnes)

Source: FAO.

Consumption and distribution of dairy products

Compared to the rest of Africa, the consumption of milk products in Malawi is very low, which is caused mainly by low purchasing power, limited supply and poor distribution beyond the main urban and trading centres (CYE Consultant, 2009). In fact, according to Imani Development Consultants (2004), Malawi has the lowest consumption of milk per capita in Africa estimated at 4.7 kg/capita/year compared to an Africa average of 15 kg/capita/year (CYE Consultant (2009) estimate these figures as 4 and 20 litres per capita, respectively).

Historically in Malawi, most consumers used powdered milk and where fresh milk is unavailable or is inconvenient to buy, powdered milk still forms the main form of milk consumed. Fresh pasteurised milk has traditionally been sold only to the higher and middle income groups.

Sales and consumption of milk is heavily concentrated in the urban areas. The retail sector is dominated by the large supermarkets such as People's Trading Centre (PTC) and Shoprite. Besides large supermarkets, milk is also sold by small convenience stores, informal shops in low income housing areas, vendors and trading stores outside of the three main cities. It has been reported that selling to retail outlets gives the highest profit margin to processors, due to the fact that the milk can be sold to them in bulk..

In addition to processed liquid milk there is also a considerable supply of milk powder in tins and packets in urban areas. The tins tend to be sold in the bigger stores that are targeting upper and middle-income consumers, whilst the packets and sachets are sold in smaller retailers targeting lower income consumers. Milk powder is very important to smaller retailers, because many of them do not have refrigeration facilities. It is though interesting to note that small retailers are able to sell milk at the same price as the large retailers.

As pointed out in Chitika (2008) studies have shown that informally marketed milk is associated with zoonotic health risks (which include brucellosis, coliforms and bovine tuberculosis) and high bacteria counts which are due to poor hygiene and a long time lag between milking and sale. The absence of pasteurization increases the risk posed by such organisms. There is therefore a need for effective control measures including hygienic handling of milk and its pasteurization to protect public health. However, actual health risks from bacterial contamination are judged to be low because of the common consumer practice of boiling milk before consumption.

Information on how the consumption of dairy products in Malawi reacts to changes in expenditure and prices is limited. Although, Ecker and Qaim (2011) estimated expenditure and Marshallian own price elasticity for food products using the 2004-05 Living Standards Measurement Survey for Malawi. Their results for milk and dairy products are presented in Table 2. On average, urban consumers react more to changes in expenditure but less to prices than rural consumers. Furthermore, the income elasticities indicates that milk and dairy products are “luxuries” for the urban population while “necessities” for the rural population. The reason for these differences are not clear and deserve further research as they might be due to the aggregation amongst several different type of products of different qualities.

Table 2: Consumer's expenditure and Marshallian own price elasticities for milk and dairy products

Elasticities	Rural				Urban			
	Average	Lowest	Middle	Highest	Average	Lowest	Middle	Highest
Expenditure	0.870	0.877	0.868	0.849	1.514	1.580	1.599	1.079
Price	-0.746	-0.509	-0.691	-0.827	-0.551	-0.542	-0.627	-0.564

III. International development donors in the dairy sector in Malawi

Dairy is considered a key investment sector within agriculture for the Government of Malawi (MIPA, 2011) and donors such as the USA (through USAID, United States Agency for International Development), Japan (through JICA, the Japan International Cooperation Agency) and Belgium (through FICA, the Flemish International Cooperation Agency) have focused part of their development aid on the sector (in the case of USAID this has been with the participation of the Land O'Lakes firm since 1999).

According to Imani Development Consultants (2004), donor support has assisted the Government in the goal of meeting its stated objectives of development of the dairy sector, namely: to promote dairy production so as to achieve self-sufficiency in dairy and dairy products; to exploit export markets when surpluses arise; to contribute to welfare of Malawians by providing dietary animal products and; income generating activity through higher levels of production and competitive marketing systems.

The purpose of this section is not to provide a detailed description of all the work far that different donors are carrying out in the dairy sector in Malawi, but through the description of two different work programmes in the country, highlight two different

development strategies pursued by donors. The first strategy can be portrayed under the tag of “Strengthening the formal dairy sector” (as exemplified by the USAID support through the work undertaken by Land O’Lakes) while the second strategy can be classified “Development of local supply chains” (identified with work supported in Africa by the JICA).

“Strengthening the formal dairy sector” strategy

Under this strategy we briefly consider the main characteristics of the work of three donors: USAID through Land O’ Lakes; the EU support through their involvement with the Shire Highland Milk Producers Association and; the work supported by FICA.

The Land O’Lakes Dairy Sector Development Programme

USAID sponsored the Land O’Lakes’ dairy sector development program, which started in 1999. According to Land O’Lakes (Buck, 2009) the goal of this project was to increase rural incomes by increasing the number of rural poor households deriving their main livelihood from dairy business, through managing high productivity enterprises, while delivering improved quality and affordable dairy products to the market. The total investment in the sector was US\$ 11.0 million, of which US\$ 2.5 million were USAID direct investment plus US\$ 8.5 million in leveraged funding.

Their key project components comprised: development of efficient milk producer organisations; development of efficient dairy processing and marketing and; expansion of effective industry support services.

Their development strategy can be described as being based on the results of value chains analyses of the dairy sector. Buck, (2009) highlights the following specific aspects of these analyses:

- a. **Milk quality** - Their diagnosis is that milk is of poor quality, not meeting international standards and there is a lack of certified laboratories. Therefore, their programme promotes milk traceability systems and services and facilitating upgrading of laboratory methods and equipment.
- b. **Supply** – They found seasonal variation in production associated with the dry season and lack of availability of forage and pasture seeds. In response to this, the programme promotes use of water development and silage making services and action-oriented research into new seed varieties.
- c. **Policy** – They considered that the sector had inadequate animal feed quality standards and that the industry associations have limited resources, so they propose to facilitate technical revisions to and advocacy for enactment of animal feedstuffs act and to facilitate capacity building of the associations to increase revenue collection and service provision.
- d. **Market** – They found that export requirements were not well understood by the industry and there was low per capita milk consumption. Their programme proposed stimulating the export market facilitation services and facilitating industry-led consumer awareness campaigns to promote purchase of quality milk.
- e. **Producers** – Their value chain analysis found that producers had high cost and use poor quality commercial feeds. In addition, they lacked access to appropriate

financial services. Therefore, their programme promoted the use of improved feed formulation and testing services and the innovative delivery of financial services and development of new financial products.

- f. **Milk bulking groups** – They found milk losses due to lack of cold chain infrastructure and lack of guaranteed market for members' milk. Their strategy to address this consisted of facilitating links to financial service providers and promoting guarantee schemes with processors. They also proposed to facilitate vertical linkages and promote use of supply contracts between the milk bulking groups and the processors.
- g. **Processors** – The value chain analysis found that the quality of processed milk was not aligned with export standards and that they suffered of margin squeeze affecting profitability. They proposed to promote quality assurance services and to increase access to market information and the link to business sector programmes to develop higher-value products and markets.
- h. **Inputs and Services** – For this stage of the chain they found that there was a lack of awareness of financial service options and that the return on investment of providing in-house services and/or inputs was low or unknown. As a result, they proposed to encourage financial service providers to expand marketing of existing and development of new financial products and to promote feasibility studies and pilot programmes for new, innovative services, inputs and technologies.

Finally, in order to develop a sustainable dairy sector support system, Land O'Lakes stated its intention was 'to source local and regional training and technical providers to assist in the development of the sector including a strong emphasis to be placed on the integration of the current local dairy service providers into the project'.

The Shire Highland Milk Producers Association

The Shire Highlands Milk Producers Association (SHMPA) is a farmers' organisation established in 1985 to look after the interest of smallholder dairy farmers in the Southern Region. It has a membership of 2,900 dairy farmers who sell their milk through the SHMPA managed milk collection network. This network consists of 20 milk bulking groups within an 80 km radius of Blantyre. According to Imani Development Consultants (2004) the main funders of the project were the EU and Oxfam.

The activities carried out by the SHMPA include: milk collection centre maintenance; establishment of new collection centres; provision of AI services; election and training of milk bulking group committees; auditing of milk bulking group accounts; advocacy for smallholder dairy farmers – especially concerning milk marketing, input supply and field services; farmer training in dairy farm management; operating a heifer loan scheme; heifer breeding for new farmers and; provision of sustainable farmer-managed animal breeding and health services.

In addition to the resources from donors, all farmers pay a small levy on milk sold to cover the costs of SHMPA's activities. SHMPA's activities have had a positive influence on dairy farming in the Southern Region as they also help farmers to establish dairy farms under the Heifer loan scheme and provide field extension services (Imani Development Consultants, 2004).

In 2009 the Flemish government awarded the Malawi Milk Producers Association the sum of €500,000 for a four year project (FICA, 2011). The objective of the project is to strengthen the dairy sector in the central and northern regions of Malawi by targeting four areas: capacity building and training of the farmers and the milk bulk groups; reinforcing the capacity of the associations; improving the technical services and; increasing the cattle numbers.

By targeting the direct link between farmers and the milk bulking groups, the objective of the project is to raise milk production from its current low level, through adequate training and management. Furthermore, existing farmers as well as potential new entrants into dairying will be educated in marketing, hygiene and quality control.

At an institutional level, the associations staff members are trained to improve management practices with the aim achieve sustainability of the associations. This means among other things general and financial management, leadership, marketing, etc. One important task of the associations is to provide information to its members on the wellbeing of the animals, nutrition, artificial insemination, barn construction, etc. Through bundled purchase of inputs, such as seeds, by the regional associations, the associations can ensure that the farmers will pay less than if they were negotiating individually and in time the association will be able to operate independently that way. A well-run association that provides professional services will gain more members and farmers can continue to make the change from informal dairy production to a more formal dairy production.

“Development of local supply chains” strategy

The approach followed by JICA is analysed in Kurokawa et al. (2008)⁹ and has many aspects in common with the strategies already reviewed, as it is also focused on the development of the private sector in Africa. The strategy is known as One Village One Product (OVOP) approach and is based on as a “strategic movement” which relates closely to regional development policies. It has its origins in Oita, one of the 47 prefectures of Japan. It began in the 1970s as a community-based business activity aimed at rediscovering and revitalising economically backward rural areas. The movement was introduced in 1979 by former governor of the Oita Prefecture in Japan, Dr. Morihiro Hiramatsu. Under the OVOP movement each village is encouraged to produce at least one product or service which can be showcased across the country and the world (Kurokawa et al., 2008, p. 23).

JICA considers that the major constraints on the performance of SMEs include costs and access to finance (considered the major resource constraint), access to electricity, corruption, tax administration, level of skills and transportation. Furthermore, they consider that many of the binding constraints are due to the presence of market and

⁹ This is a working paper produced by the Overseas Development Institute (ODI) jointly with JICA. The paper reviews JICA’s strategy producing a strengths, weaknesses, opportunities and threats (SWOT) analysis and comparing it with other donors’ strategies, unfortunately, despite the spread presence of USAID in Africa, its strategy is not included in the paper.

government failures, which justifies support for private sector development. The OVOP approach is located at the micro end of the spectrum of donor activities since it aims to provide specific support for individual firms, groups of firms and / or households.

The OVOP programme in Malawi is relatively small with an investment of \$500,000 supporting four dozen projects. The programme aims to develop products and services through value adding by communities and using locally available resources in a designated area. Specifically, it aims to: promote the OVOP concept approach of economic development at the level of villages; promote value adding technologies, such as agro-processing, quality control and packaging, at the village level; to facilitate small-scale business skill development at the village level; to promote market linkages between products and services from villages and domestic / international markets.

As pointed out by Kurokawa et al. (2008) the Malawi OVOP Programme had at the time of the study supported 46 projects for 12,943 beneficiaries, including activities on: dairy processing; fish processing; vegetable production and processing; rice milling; honey production and mushroom production. One group, for example, received technical support from the programme and built a multi-purpose model factory where members successfully managed to produce commodities like confectionary, cooking oil, and milk from soy beans and other products. Some of the OVOP products have been exported to South Africa and Japan.

The Bvumbwe Milk Cooperative, formed in 2003, was one of the first projects to be funded by OVOP. Bvumbwe received a loan of around US\$12,000. JICA helped dairy farmers in Bvumbwe who had a milk bulking group to form a cooperative. It also procured a cooling tank which the cooperative uses to store its milk before it is sold to the Dairibord, the largest consumer of raw milk in Malawi.

It should be noted that under the OVOP programme the Bvumbwe Milk Cooperative cooperative has improved productivity and reduced the losses of milk collected from its members. Milk production has increased from 13 litres to 27 litres per animal per day. The establishment of the cooperative has made it possible for them to negotiate with Dairibord better prices as quality of milk produced is of high standard. This has also led to an increase in the number of farmers and animals in the cooperative, increasing from 12 to 117. JICA supplied the Bvumbwe with a milk pasteuriser and milk packaging machine in 2003 for the cooperative to sell milk directly to consumers and not through the major milk companies (One village one group (OVOP), 2011).

IV. Discussion

The purpose of this section is to cover two main issues: First, to discuss why the two approaches followed by the donors for the Malawian dairy supply chain potentially conflict. Second, to show that the choice of strategy is dependent on the nature of competition within the sector, that is whether it is perfectly competitive or whether the processing sector has the capacity to exercise market power. It should be noted that in the absence of statistics to test the degree of market power, we discuss this using secondary data collected as part of value chain analyses and the approach suggested by Landes and Posner (1981) for cases of market power in antitrust cases.

Why the two donors' strategies potentially conflict

From the review of the donors' strategies it is clear that both pursue similar goals, which can be represented by Figure 4. Panel a of the figure represents a stylised version of the current consumption market for milk¹⁰, which can be classified into high quality demand and supply for milk (denoted by the supra-index H) and low quality demand and supply for milk (denoted by the supra-index L). As shown in the figure the formal sector sells a low quantity of high quality milk (i.e., pasteurised) at a high price, while the informal sector sells a large quantity of low quality milk at a lower price than the formal sector. The presence of two demand curves is due to the fact that the population can be considered as segmented by income, so the high quality milk is sold to the affluent urban group and the low quality milk is sold to the rural and poor urban population. Panel b of the figure can be considered as the situation targeted by the donors', as the high quality milk replaces the low quality milk and the supply expands sufficiently to serve both the rural and urban population. Of course, the difference between the two strategies discussed in this paper is in the way to move from the situation in Panel a to Panel b.

Figure 4 – Malawi dairy market: stylised current situation and target situation

It is clear from the review of the donors' strategies that they have a great number of features in common, such as increasing the efficiency of milk producers through micro credit, knowledge transfer, empowering producers organisation, etc. Therefore, we focus on those aspects that may lead to conflicts between the two approaches

Overall the comparison between the two strategies can be seen as two different views of what to do with an ineffective/inefficient supply chain. On the one hand, the strategy of strengthening the formal dairy sector followed by USAID and others is aiming to revamp a supply chain that it is in disarray and their strategy involves the entire supply chain. On the other hand, JICA's OVOP strategy aims at creating local supply chains that sell processed milk directly to consumers, bypassing the formal sector. Furthermore, their strategy does not, to our knowledge, encompass supply chain stakeholders beyond the producers (and of course their associations).

¹⁰ In order to maintain the discussion in simple terms and focused on the donors' strategy, we abstract from the role of imports of milk powder in the Malawi dairy market.

At the most direct level of comparison both strategies are actually in conflict with each other because a key feature of the formal dairy sector is the presence of significant excess capacity in processing that appears to arise because of the low supply of milk to the processing sector. The aim of USAID and the other donors' strategy is to expand that supply of milk, while JICA's strategy of supporting direct marketing of pasteurised milk to consumers worsens the situation by reducing the supply of milk to processors and increasing their level of inefficiency

A more substantive comparison involves considering each strategy as an approach to development. On the one hand, the USAID and others are betting on a formal sector that can be strengthened to replace the unsafe informal market and satisfy an undernourished population with safe dairy products at affordable prices. On the other hand, JICA's strategy implies (though should be noted that this is not explicitly stated) to bypass the ineffective formal sector to create a local supply of safe dairy products at affordable prices that can replace the informal sector.

In our view, which of the above mentioned strategies is more appropriate for the development of a dairy sector in Malawi, will depend in great measure, on whether the dairy sector is a competitive one, i.e., whether the processing sector (and also the retail sector) has market power.¹¹

If the processing sector is not competitive, then, all the work of USAID and others to expand the supply of milk might be wasted as producers will continue to receive low prices for their milk, the supply of high quality milk will still be insufficient for the population, affluent urban consumers will continue paying high prices for their milk and the informal market will remain. In this context, JICA's strategy might be appropriate because it will not only ensure the expansion of the supply of high quality milk but also "discipline" the non-competitive processing sector and force them to expand to compete.

On the other hand, if the processing sector is competitive but inefficient, JICA's strategy worsens the situation by reducing the amount of milk available to processors due to encouraging direct marketing of milk and investment should be directed at revamping the processing industry together with expanding domestic milk production.

In the next section we deal with the issue of market power in the Malawian formal dairy sector.

Measuring imperfect competition in the Malawian dairy sector

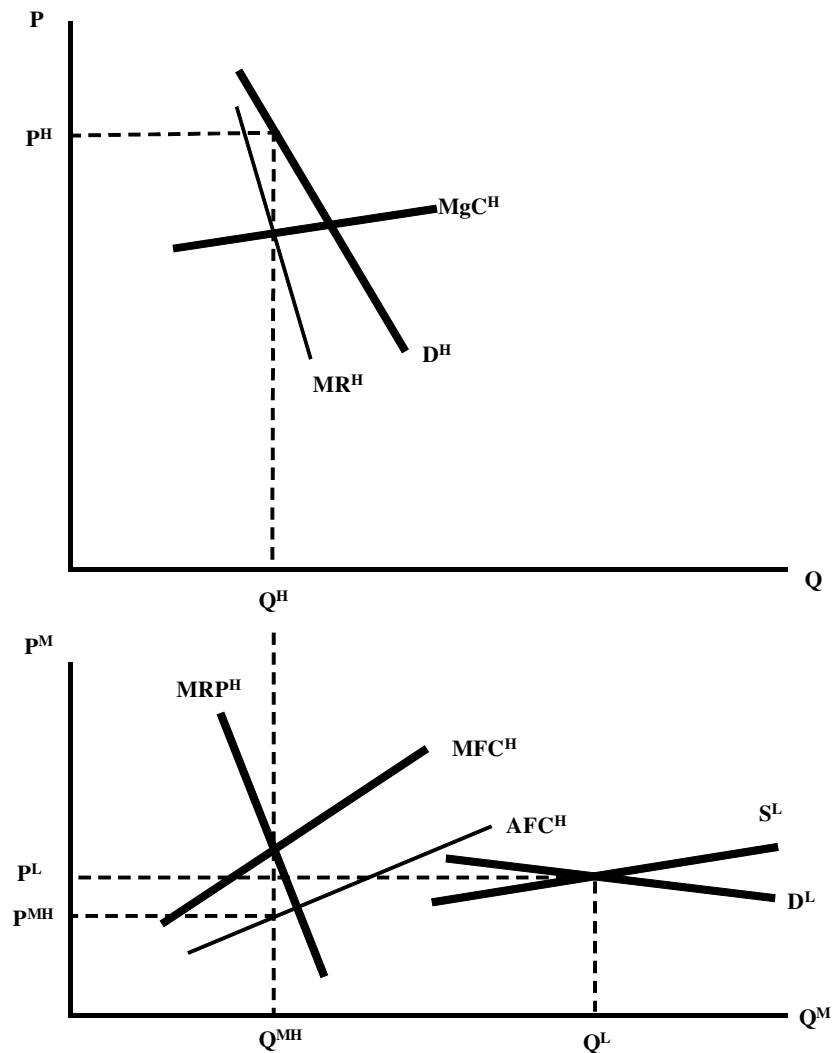

The purpose of this section is to analyse the question whether the formal dairy sector operates in a non-competitive way with respect to urban consumers paying high prices

¹¹ It should be evident that the issue of market power is a necessary condition but not sufficient to prefer one alternative strategy to the other. That decision will need to be based on the consideration of multiple aspects each of which would need to be 'weighted'. These aspects could be: employment generation; multiplier effects on the wider population; sustainability of the strategy in terms, for example, whether it will generate resources that can be reinvested to replace the capital (at the least); etc.

for the dairy products and with respect to producers receiving low prices for the milk. Due to the lack of available time series data for the dairy sector, the analysis is done based on the available information arising from value chains analyses that have been carried out for the sector.¹²

The reason why market imperfection may fit the stylised facts that were described in the overview of the Malawi formal dairy sector can be explained by means of Figure 5. This figure presents two vertically connected markets. The top diagram represents the situation of the market for processed milk product, while the bottom one the market for unprocessed milk. To simplify exposition (and the diagram), we consider in the figure the situation where processing firms are acting collusively and therefore it corresponds to the situation where it acts a monopoly in selling (top panel) and a monopsony in buying (bottom panel) .

Figure 5 – Malawi dairy market under imperfect competition situation

¹² If time series were available the degree of market power could be studied by the approach presented in Schroeter (1988) or Azzam and Pagoulatos (1990).

The result of market imperfection is that affluent consumers pay more (P^H) for the pasteurised milk and the firms produce less (Q^H) than in perfect competition (where the demand D^H intersects the marginal cost of the processing firms MgC^H).

The situation in the unprocessed milk market comprises two differentiated sub-markets: (1) the market for milk to be pasteurised and (2) the informal milk market. For (1), the result of the “monopsony”¹³ situation is that processors demand less milk (Q^{MH}) and pay a low price for it (P^{MH}) and dairy producers market the bulk of their milk in the informal market, where they sell Q^L at a price P^L , which can be higher or lower than the price paid by the formal sector, depending on factors such as the price elasticity of the demand and supply for low quality milk (D^L , S^L), and the total amount of milk produced.

It is important to mention that the degree of competition in the dairy market has been mentioned in the value chain analyses, but only in a marginal way. For instance, this can be illustrated with reference to the report by Kedrock and Agar (2007) for USAID, which indicates that “the three operating medium processors [i.e., Lilongwe Dairy, Dairibord, and Suncrest] are reportedly profitable while running at only 20-35 per cent of capacity utilization. This is possible because they target the top 3 per cent of the population (375,000) with the highest disposable income that are relatively price insensitive. This conservative approach removes a good portion of the risk, but it does limit growth and volumes” (Kedrock and Agar, 2007, p. 32). The same authors also state that “Processors also are reported to pay low prices paid for raw milk” (Kedrock and Agar, 2007, p. 30). Despite that evidence the same authors indicate that while the formal processing level is highly concentrated, “it appears to be reasonably competitive. The production level is fairly well organized through associations and MBGs. Milk moves from source to processor and consumer fairly effectively, if not always efficiently, though it is not uncommon for tankers of milk to be lost from non-collection due to poor roads and breakdowns” (Kedrock and Agar, 2007, p. 32).

Processors’ potential oligopoly power

While as mentioned it is not possible to estimate the degree of imperfect competition due to the lack of readily available time series, it is possible to explore the degree of market power of the processing companies by estimating the Lerner index (L) for each firm based on secondary information provided in the value chain analyses. Thus, in this paper we follow the approach by Landes and Posner (1981) of computing the L for a dominant firm. The L for a firm i is given by:

$$(1) \quad L = \frac{(P - MgC_i)}{P} = \frac{1}{\varepsilon_i^d}$$

¹³ MRP^H denotes the derived demand for milk by processors, MFC^H is the marginal cost of the milk producers serving the high quality market and AFC^H is the average cost of those producers.

Where P is the output price, MgC_i is the marginal cost of the firm i and ϵ_i^d is the absolute value of the demand elasticity faced by firm i (i.e., elasticity of the residual demand defined as $Q_i^d = Q_m^d - Q_j^s$, where Q_m^d is the total demand and Q_j^s is the total supply of all the competitors to firm i (i.e., j firms). Differentiating the residual demand for i with respect to the prices and transforming the expression into elasticities and shares, one obtains the expression for the elasticity of the residual demand faced by firm i , which is given by (2):

$$(2) \quad \epsilon_i^d = \epsilon_m^d \left(\frac{1}{S_i} \right) + \epsilon_j^s \frac{(1 - S_i)}{S_i}$$

Where S_i is the market share of firm i defined as Q_i^d / Q_m^d , ϵ_m^d is the market demand elasticity and ϵ_j^s is the supply elasticity of firms j . The strategy to estimate L for each firm consists of replacing in the formula the estimated demand shares and elasticities.

One problem is the lack of available data for the elasticity of supply of the firms. Due to this Table 3 presents the values of L conditional to possible values of the supply elasticity of competitors. In the presence of idle capacity one would expect the supply elasticity to be around one or higher as the firms would not have constraints to expand production in response to an increase in price. Therefore, we assume several values for the elasticity of supply ranging from 0.8 to 2.

Table 3: Lerner index (L) for the processing companies conditional to several competitor supply elasticities

Companies	Supply elasticity 2/					Shares
	0.8	1	1.2	1.5	2	
Dairibord	0.87	0.81	0.76	0.69	0.60	70
Suncrest	0.12	0.11	0.09	0.08	0.07	15
Lilongwe Dairies	0.08	0.07	0.06	0.05	0.04	10
Northern Dairies	0.04	0.03	0.03	0.03	0.02	5

Notes:

1/ Market demand elasticity used for the exercise was -0.564 (highest quintile in urban areas).

2/ Supply elasticity of all the competitors together.

The results of Table 3 indicate clearly substantive market power for the Dairibord company under our assumptions.

Processors' potential oligopsony power

To provide a measure of the degree of market power in the input market (i.e., milk) through an index similar to the Lerner index, i.e., by using the inverse supply elasticity for milk, is more difficult due to the lack of information on the informal market.

One should expect that some degree of market power should exist in the input market. In this sense CYE Consult (2009) speculated that with the low volume of milk being supplied, it was difficult to understand why the same price was paid throughout the year to dairy farmers, when common practice in other parts of the world was to increase the price paid to dairy farmers when seasonal production naturally goes down for example when cold weather or dry conditions reduce the amount of green feed available. This paradoxical result can be partially explained by the fact that processors have the possibility to use reconstituted imported milk powder in their production of dairy products. This could make the derived demand for milk for processing more elastic and reduce the demand for domestic milk if producers sought higher prices.¹⁴

Another reason for speculating the presence of some degree of market power in the input market is the fact that according to OVOP (2011) one of the reasons for the establishment of the cooperative is to negotiate with Dairibord better prices. Although this is mentioned as regards a reward for milk of higher quality, it also may imply that Dairibord has the capacity of setting prices.

It may be speculated that the supply elasticity for milk faced by processors is high (although not constant) if one considers that a sizable amount of the milk produced is destined for the informal market. Thus, a substantive increase in the price offered to producers might move milk from the informal to the formal market. Of course, unless the price in the formal market exceeds the informal market price, the milk supply to the formal market should continue to be inelastic and determined by reasons such as those explored by Chitika (2008) as discussed earlier.

V. Conclusions

As pointed out by Mazumdar and Mazaheri (2003) in the preface to their study of the African manufacturing sector, it continues to face many problems as it struggles to progress from its underdeveloped state and that its development is an important condition for improving African living standards.

The purposed of this paper has not only been to portray the situation of the Malawi dairy industry, but also to show the need of international donors to coordinate their development plans. This case study shows the need for detailed discussion on the actions to be taken within a country (not a continent) including the underlying rationale because they do in the end guide the allocation of scarce resources.

In the particular case of the dairy sector in Malawi, the results indicate the need of further analysis of the degree of competition of the formal sector, particularly the processing industry, and this needs to be taken into consideration when drawing up

¹⁴ A related issue can be found in the discussion of whether the monetisation of milk powder as part of USAID's Programme of Food for Peace would distort the Malawian dairy domestic market (Fintrac Inc., 2008). Thus, on the one hand, Fintrac Inc., in their report produced for USAID to provide guidance about what commodities should be monetised, stated that selling milk powder to processors would expand their production and reduce their prices with obvious benefit to consumers. On the other hand, Land O' Lakes made it clear that it did not support milk powder for monetization due to its possible effects on the domestic market.

plans for the development of the sector. Furthermore, this analysis needs to be done using better data than that previously collected for the various value chain analyses that have been carried out on behalf of donors.

Finally, to highlight the importance of analysing the structure of domestic markets, it should be noted that the Malawian case is not an isolated one as there are several supply chains born from industrialisation processes which are characterised by high levels of idle capacity, the production of a narrow range of products that are expensive with important implications not only for economic development but also for food security.

The discussion of whether to invest in improving ineffective supply chains or apply alternative approaches is even more important as other strategies are being considered by developing countries (see for instance, Jiaqi and Lambert, 2002 or Omore et al., 2004) consisting of “small-scale dairy supply chains” (i.e., through small-scale marketing and processing facilities) as a way to significantly contribute to employment in rural, peri-urban and urban areas. This approach aims to improve the quality of milk destined for the informal markets. However, as pointed out, whatever the development approach followed, it needs to be based on solid evidence, and the impacts of different strategies need to be compared by the use of a number of important development indicators.
