## FORECASTING BY ECONOMETRIC MODELS AS SUPPORT TO MANAGEMENT

TINDE DOBRODOLAC

Faculty of Economics Subotica  
University of Novi Sad, Serbia

UDC: 330.43; JEL Classifications: C10

**Key words:** Forecasting, econometric models, management.

**Abstract:** In the contemporary environment characterized by the dynamic structure of factors and the unpredictability of the relations existing between them, the central problem is the selection of strategic goals. Forecasting is the necessary precursor to the planning process and includes research into the future course of events. Numerous methods and techniques of forecasting are used nowadays. Econometric models can be used successfully for predicting the future development of a phenomenon, and thereby facilitate the choice of strategic goals.

### Research results

This paper uses data published by the Republic Office of Statistics of Serbia, obtained through Household Consumption Surveys.

The Household Consumption Survey is one of the oldest surveys conducted by the Republic Office of Statistics. The methodology of this survey has been revised several times since 1954, in order to obtain as reliable results as possible.

Since 2003, this research has been conducted in accordance with international standards and recommendations of EUROSTAT, ILO and UN, thus providing international data comparability. The survey gathers data on income, expenditure and household consumption, i.e. data on the basic elements of individual consumption.

A survey unit is taken to be every single or multi-member household, selected according to the sampling plan. A household is defined as: (a) a community of persons, whose members live, eat and jointly spend the earned income; (b) a single person living, eating and spending the earned income on his/her own.

200 households are surveyed every 15 days, i.e. 1200 households quarterly.

The gathered data refer to total disposable income, expenditure on food and non-alcoholic beverages, and the share of this expenditure in quarterly total individual consumption as well, and constitute the monthly averages per household (expressed in RSD and percentages). The data for all households were recorded separately for Vojvodina and the Republic of Serbia, for all households (Table 1).

Viewing the trends in the values of disposable income and expenditure on food, as well as the share of expenditure on food in total individual consumption over time, one can follow the trends in the population's living standard.

One of the most suitable formats for representing data over time is a chain index series, which can be used for calculating the mean development rate, i.e. the mean growth rate of a phenomenon. The graphic representation of chain index trends is shown on the Figure 3 (Appendix).

Based on the above figures, we can notice that trends in disposable income and expenditure on food show a growing tendency over the observed period both in Vojvodina and the Republic of Serbia. Moreover, we can see that, in the structure of the households' individual consumption structure, the expenditure on food and non-alcoholic beverages account for a high share - 36.64% in Vojvodina and 39.47% in Serbia (on the average for the observed period), and in addition, show a slight growing trend, which is a characteristic of undeveloped countries.

In most EU countries, the highest share in the individual consumption structure is taken up by expenditures on dwelling, water, power, gas and other fuels and transport, while expenditure on food and non-alcoholic drinks takes up the third place.

According to the latest Communication of the Serbian Republic Office of Statistics, in the fourth quarter of 2009, an average household in Serbia has the disposable monthly income amounting to 47582 RSD. At the same time, the average household expenditure amounts to 44886 RSD, where expenditure on food and non-alcoholic beverages amounts to 18249 RSD, i.e. 40.7%, which points to a fall in the population's living standards.

The Figures 4 and 5 (Appendix) show the average overlapping variance between data for disposable income and expenditure on food, used in econometric research.

Based on the t-test, we can conclude that there is no statistically significant difference between the actual value of expenditure on food and the ones forecast by economic model for the 3rd quarter of 2009, which means that we can consider the model's forecasting ability to be satisfactory with the probability of 95%, both in case of Vojvodina and the case of the Republic of Serbia

Based on the F-test, we can also conclude with the probability of 95% that the structural parameters are stable, both in case of Vojvodina and the case of the Republic of Serbia, i.e. that there is no statistically significant difference between the sums of squared residuals for the shorter (18 observations) and longer sample (21 observations), which means that the model's forecasting ability is satisfactory.

By this we have proven that *parameterized econometric models are also suitable for forecasting*; the results are in accordance with forecast values based on the trend and the mean development rate (see Table 2)

This research indicates to the management that there is reason for concern, in view of the fall in the population's living standards, i.e. the growing trend in the share of expenditure on food in Total individual consumption.

### Conclusion

The pace of change of events nowadays is too rapid for experience to be used as a guide for the future. New conditions are characterised by unpredictable and complex problems and possibilities as well as uncertain situations, so that planning and forecasting should secure better results in accomplishing an organisation's objectives.

Planning in modern conditions comes down to defining objectives and formulating strategies for achieving them. The management's main responsibility in the new conditions comes down to formulating and applying the strategy. Anticipating changes is not only a challenge but a prerequisite for the survival of an organisation in a dynamic setting. Forecasting by econometric models is an area that provides for planning and selection of strategic objectives. A large number of forecasting methods and techniques are used nowadays.

Ideal forecasting is achieved by combining two types of methods: the group of methods based on intuition and subjective assessment; and the group of methods relying on statistical and mathematical techniques, including econometric methods.
