# WORLD DEMAND PROSPECTS FOR COTTON

IN 1980

WITH EMPHASIS ON TRADE BY  
LESS DEVELOPED COUNTRIES

1980

FAER 68  
ABSTRACT

World demand prospects and future supply sources of cotton lint and textiles are examined to determine their implications for the export earnings of the less developed countries (LDC's). World cotton consumption in 1980 is projected to be 14.8 million metric tons, compared with 11.3 million tons in 1967. Cotton's share of total fiber consumption will drop to 48 percent. By 1980, the LDC's will account for about half of the world's cotton production and two-thirds of cotton lint exports. Trade in cotton textiles will increase and by 1980 about half the world's exports will originate in the LDC's. LDC net earnings from trade in cotton lint and textiles combined could reach \$1.5 billion by 1980--over \$600 million above estimated average 1965-67 earnings.

Key words: cotton, developing countries, textiles, foreign trade, commodity projections

\*\*\*

Results of the project of which this report is a part have been published as follows by the Economic Research Service:

World Trade in Selected Agricultural Commodities, 1950-65

- Vol. V.--Oilseeds, Oil Nuts, and Animal and Vegetable Oils. Foreign Agr. Econ. Rpt. 47, Aug. 1968.

Japan's Food Demand and 1985 Grain Import Prospects. Foreign Agr. Econ. Rpt. 53, June 1969.

World Demand Prospects for Agricultural Exports of Less Developed Countries. Foreign Agr. Econ. Rpt. 60, June 1970.

World Demand Prospects for Wheat in 1980 with Emphasis on Trade by Less Developed Countries. Foreign Agr. Econ. Rpt. 62, July 1970.

Copies of these reports may be obtained upon request to the Division of Information, Office of Management Services, U.S. Department of Agriculture, Washington, D.C. 20250.

Additional reports are being developed on the following as part of the overall research project: World demand prospects in 1980 for rice; total grain; oilseed and meal; citrus fruits; coffee, tea, and cocoa; and bananas; the Japanese grain-livestock economy; and world agricultural import barriers. Publication of these reports will be announced.

## FOREWORD

Recently cotton has come under severe competition from manmade fibers and has been receiving a declining share of the market. This decline has been of concern not only to policy makers in the developed countries but in the developing ones as well. Further, cotton exports have been important sources of foreign exchange in many of the latter countries. Hence, the present investigation was designed to analyze the world demand prospects for this commodity at the onset of the next decade.

World cotton consumption is expected to be approximately 30 percent higher in 1980 than in 1967, assuming medium rates of income growth and a 26-cent price for SM 1-1/16 inch cotton, Liverpool. This increase is expected despite the fact that cotton's share of total fiber consumption is likely to decline from 57 percent in 1968 to 48 percent or less in 1980.

The pattern of world cotton trade is expected to change substantially during the next 10 years. At the end of that period, almost half of the world's cotton textile exports will originate from less developed countries. Also at that time the world cotton lint trade is expected to increase 900,000 tons over the 1965-67 average, with 25 percent of the total being imported by less developed countries. At the same time this group is expected to export 67 percent of the total lint, compared with 61 percent in 1965-67. Clearly, there are implications in these projections for economic growth for cotton-producing countries, especially the developing ones. In light of their requirements for foreign exchange, this study suggests that expanding international markets for cotton can provide less developed countries some additional impetus for economic developments.

This study is part of a research project on "Demand Prospects for Agricultural Products of Less Developed Countries" conducted by the Economic Research Service under a participating agency service agreement for the Agency for International Development.

# EXPLANATORY NOTES

M.T. = Metric tons.

- = Insignificant amount.

+++ = Extremely large percentage increase.

W.S. = Wrong sign on coefficient.

Neg. = Negative quantity.

n.a. = Not available.

(10) = Parenthesis around numbers in tables indicate estimate by authors.

(10) = Numbers in parenthesis and underlined refer to items in Literature Cited.

"Textiles"--Includes yarn, fabrics, clothing, and other manufactures (the last two to the extent statistics are available).

"All or total fiber"--Includes cotton, wool, cellulosic (rayon, acetate, etc.), and synthetic or noncellulosic (nylon, polyester, etc.) fibers. Flax, silk, and fiber glass are usually excluded.

"Cotton" or "Cotton lint"--Refers to ginned cotton (cotton with seed removed).

"LDC's" or "LDR's"--Less developed countries or regions.

"DC's" or "DR's"--Developed countries or regions.

"CPC's" or "CPR's"--Central plan countries or regions.

## SUMMARY

World cotton consumption is projected to rise from 11.3 million metric tons in 1967 to 14.8 million tons by 1980, assuming medium rates of income growth and a 26-cent per pound price for SM 1-1/16 inch cotton, Liverpool. The less developed countries (LDC's) are projected to supply half of this demand and to earn \$1.5 billion net in foreign exchange from the export of cotton lint and textiles combined.

Projections of 1980 consumption at other cotton prices range from 14.6 million tons at 30-cents per pound up to 15.0 million tons at 24-cents. Higher assumed rates of income growth in the LDC's raise projected world consumption by 1.3 million tons, while lower rates reduce projected consumption by 0.6 million.

Cotton's share of world fiber use in 1980 is projected at 47-48 percent, compared with 57 percent in 1968. Although per capita consumption of total fibers will increase greatly in developed countries (DC's), that of cotton will decline because of competition from manmade fibers. Per capita cotton consumption will increase moderately in the central plan sector (East Europe, the USSR, Mainland China) and will climb slightly from the present low level in the less developed countries.

Foreign world (non-United States) cotton production in 1980 is projected to range from 12.5 million metric tons at a 30-cent per pound price down to 11.9 million tons at a 24-cent price. To balance world production and consumption, U.S. production would need to range from 2.1 to 3.1 million tons (9.4 to 14.3 million bales).

World cotton textile trade by 1980 will be some 40 percent above 1965-67 levels and almost half the world's exports will originate from the less developed countries, compared with 34 percent in 1965-67. The proportion of cotton textile consumption needs of most DC's met by imports is projected to increase by 1980. On the other hand, many LDC's are expected to lower or eliminate their need for cotton textile imports. Comparative costs, product pricing policies, import restrictions, and national trade and development policies, are the factors behind the projected changes in trade patterns.

World cotton lint trade in 1980 under the medium income growth assumptions is projected to approach 4.7 million metric tons--an increase of about 0.9 million tons over the 1965-67 average. Though all sectors would increase imports, the increase would be greatest in the less developed sector whose share of world cotton lint imports would reach about 25 percent. At a 26-cent per pound cotton price, exports from the less developed sector are projected to reach 3.2 million metric tons by 1980, or 67 percent of the world's exports, compared with 2.3 million tons or 61 percent in 1965-67.

Under the medium income growth and 26-cent price assumptions, net earnings of the LDC's from trade in cotton lint and textiles combined could reach \$1.5 billion by 1980--more than \$600 million above estimated 1965-67 earnings. All of the projected increase would accrue from increased net textile exports. Under the high LDC income growth assumption, the projected net export earnings of the LDC's from lint and textiles are \$307 million less than under the medium growth assumption. The smaller figure results because the projected increase in LDC consumption surpasses that of production. Under the low LDC economic growth assumption, the net export earnings of the less developed countries from cotton lint and textiles in 1980 are projected as \$4 million higher than under the medium projection.

WORLD DEMAND PROSPECTS FOR COTTON IN 1980  
With Emphasis on Trade by Less Developed Countries

INTRODUCTION

Importance of Cotton to Less Developed Countries

Cotton is a major source of foreign exchange earnings for many less developed countries. It is an important earner or a potential earner in many others. In 1966, dependence of earnings upon exports of cotton lint exceeded 75 percent for Chad, and over 40 percent for the UAR, Syria, the Sudan, and Nicaragua (table 1). Three more countries depended on cotton lint for 20 to 30 percent of their export earnings, seven for 10 to 20 percent, and three for 5 to 10 percent.

Exports of cotton textiles also are an important source of earnings for several less developed cotton-producing countries. Cotton textile exports make up almost 20 percent of total exports from the UAR (table 2). When raw cotton exports are added to the textile exports, cotton's total contribution to the UAR's export earnings come to around 75 percent. Two other cotton-producing countries with high earnings from cotton textiles are Pakistan (over 15 percent), and India (over 7 percent). Also, several less developed countries (Hong Kong, South Korea, Taiwan) import cotton lint, manufacture it into textiles, and export the textiles as a major part of their trade.

Cotton's Future Earning Ability

Considerable potential exists in many less developed countries for increased cotton production through area expansion and yield improvement. However, cotton is usually only one of various crops that could be produced in larger quantities. Adequate planning requires insight into two important questions: (1) What are the prospects for cotton as a future earner of foreign exchange? And (2) should resources in the various regions be directed toward expansion of cotton production or into production of other crops?

A third question which also arises in economic planning is the extent to which homegrown cotton should be manufactured into cotton textiles for domestic use and export rather than exported as a raw product. Many cotton-growing-exporting countries traditionally have been net cotton textile importers. However, many have recently been expanding domestic mill capacity and reducing textile imports. Should this capacity continue to be expanded at a rate faster than domestic needs increase? What are the export prospects for cotton textiles?

The desire to expand cotton textile production and exports stems from the increased value of such exports over that of cotton lint, and the increased domestic economic activity thus supported. The value added usually ranges from over 1.5 times for yarn to 3 to 6 times for clothing exports and averages worldwide to around 4 times.

\*Others who made major contributions to the study were Betty Thomas, John Foster, and Rena Perley, who assisted in the research and statistical compilations.

### Purpose and Scope of This Study

Answers to the above questions on prospects for export earnings and on resource allocation to cotton production are heavily dependent upon the future demand for cotton. The purpose of this study has been to examine demand prospects and, to a lesser extent, supply sources. Four particular areas of concern guided the research:

- (1) Anticipated expansion in future world cotton consumption (as positively affected by increasing population and income, and negatively affected by competition from manmade fibers).
- (2) The import needs of major cotton deficit regions.
- (3) The form in which these import needs will be met, and the role of cotton textiles. The future cotton lint-cotton textile trade mix.
- (4) The source from which these import needs will be satisfied and the changes in trade flows to be expected.

### Framework and Methodology

The approach taken in this study involved the following: (1) projecting regional cotton use and production at alternative prices; (2) determining regional production-use balances and potential trade flows; (3) determining the cotton lint-cotton textile mix of trade flow; and (4) transforming trade flows, trade mix, and prices into earnings estimates.

The first step was to divide the countries of the world into three economic sectors: developed, central plan, and less developed. Within these three sectors certain major cotton exporting and importing countries were analyzed separately while the others were roughly grouped together, depending upon geographic location and whether they are net cotton exporting or importing countries. The resulting regions are listed in table 3.

For each of these regions, cotton production, consumption, and trade were projected to 1980 by analyzing historical trends and other relevant factors, using both mathematical and subjective techniques. In brief, the major determinations for 1980 were made as follows:

- (1) Fiber consumption was projected by multiplying expected changes in population by projected changes in per capita consumption levels as affected mostly by increasing per capita incomes.
- (2) Cotton consumption was projected by multiplying projected fiber consumption by cotton's expected share which, in turn, was determined by prices of cotton and competing fibers and long-term trends. Adjustments were made to these projections when not compatible to direct projections of mill cotton use and net cotton textile trade.
- (3) Cotton production was projected from long-term trends in area and yields, estimated responses to price changes, and from adjustments reflecting judgments about future availability of land, comparative advantages, improvements in yields, and domestic policy.
- (4) The cotton balance or potential net total cotton (lint and textile) trade in 1980 was taken as the residual of projected cotton production over cotton consumption in each region.

- (5) Cotton lint trade and cotton textile trade were projected by expanding net total cotton (lint and textile) trade to a gross basis and then partitioning the results into cotton lint and cotton textiles in accordance with recent trends and expected changes.
- (6) Export earnings or costs were estimated as the product of trade flows and the respective prices.

Major exception to the above procedure was the United States, where cotton production and cotton lint exports were assumed to be those which would balance world production and trade at each of the alternative price levels considered. This was a simplifying assumption and does not imply a passive role for the United States, since the size of "residual" in the long run could be influenced by U.S. pricing and export policy.

## WORLD COTTON PERSPECTIVE

### Cotton Use

World cotton use reached an estimated all-time high in 1968--11.4 million metric tons or about 52 1/2 million bales (table 4). The trend during the last decade has been upward, but only at about the same average yearly rate as world population (about 2 percent per year).

Cotton use is suffering from intense competition of manmade fibers. <sup>1/</sup> Compared with a slight decrease in world per capita cotton use, consumption of manmade fibers more than doubled between 1958 and 1968. Cotton's share of world fiber use, which stood at 71 percent in 1958, dropped to 57 percent in 1968. During the same period, the share held by manmade fibers climbed from 20 to 36 percent. Wool's share dropped from 9 to 7 percent.

### Cotton Production

World cotton production in crop year 1968/69 totaled 11.6 million metric tons (53.1 million bales), just below the all-time record crop of 11.7 million metric tons (53.9 million bales) in 1965/66 (table 5). Production in 1969/70 is below the level of the previous year. The long-term trend has been upward, with occasional drops in world production resulting mainly from decreases in U.S. output.

The long-term expansion in world production resulted primarily from increased yields. The estimated world average yield in 1968/69 was 323 pounds per acre, up nearly 100 pounds over the average yields of the early 1950's. In contrast, area in cotton in recent years has been below levels of the early 1950's.

### Cotton Trade

Cotton moves in world trade as lint and as textiles. Both the total volume and value of this trade has been increasing. On a simple weight basis, recent total cotton trade has been around 5.4 million metric tons, compared with 3.4 million in the early 1950's (table 6). Valuewise, total cotton trade is currently running around \$6.1 million, up from \$5.7 million in 1960 (earlier data not available).

Cotton textiles are accounting for an increasing proportion of total cotton trade. In 1967, cotton textiles made up 29 percent of total cotton trade volume, but nearly two-thirds of cotton trade value. These proportions were up from 24 and 55 percent in 1960.

### Cotton Lint Trade

World cotton lint exports climbed from about 2.6 million metric tons in the early 1950's to 3.9 million in 1960 (table 6). Since then, cotton exports have fluctuated from 3.5 to 3.9 million metric tons, with the peak level occurring again in 1966. Exports in 1967 were around 3.8 million tons.

Cotton lint exports accounted for roughly one-third of world cotton production, with no evident up or down trends.

<sup>1/</sup> Volume data 1952-65 are USDA/FAS. Other figures and all lint value data are FAO. <sup>2/</sup> These data are more inclusive of clothing than previously.

Sources: Compiled from FAO (15, 17, 18, 19, 23, 25, and Trade Yearbooks), GATT (30, 31) and USDA (57).

## Cotton Textile Trade

Trends in world cotton textile trade are less susceptible to accurate description than raw cotton trade because of data problems. <sup>2/</sup> The general trend has definitely been upward. On a simple weight basis, exports of cotton textiles are currently around 1.6 million metric tons, double the level of the early 1950's. On a value basis, which reflects price differences and mix changes as well as quantity changes, world cotton textile exports expanded from \$3.1 to \$3.8 million, or by 23 percent in the 7-year period, 1960 (earlier data not available) to 1967.

Much of this trade expansion in cotton textiles has been in clothing items which nearly doubled in value traded, as opposed to little change in trade in yarn and fabrics. Between 1960 and 1967, clothing's share increased from 24 to 37 percent of the total value of cotton textile trade (table 7).

Cotton textile trade is also suffering from the competition of manmade fibers. On a value basis, cotton's share of total textile trade dropped from 41 percent in 1960 to 32 percent in 1967.

## Unit Value of Trade

The average unit value of textile exports exceeds that of lint by over 4 times (table 8). In 1967, the average unit value of world exports of cotton textiles was about \$2,450 per metric ton, compared with under \$600 for cotton lint. The unit value of lint trade has been trending downward since 1960; that of textiles is indefinite because quantity data for 1964-67 are more inclusive of cotton clothing than previous years.

## World Cotton Prices <sup>3/</sup>

World cotton prices have been trending downward since 1954, with sizable drops occurring in 1955, 1956, and 1958 (fig. 1). The average price in 1958 was about 31 cents per pound for SM 1 1/16 inch cotton, c.i.f., Liverpool, compared with over 45 cents (constant 1968 currency) in 1954. Prices strengthened in 1959 and 1960 before beginning a gradual decline to about 29 cents in 1968. The indications for the 1969/70 crop year is for price to average around 28 cents.

<sup>2/</sup> The principal problem is aggregation. Cotton textiles include yarn, fabrics, clothing, and manufactured articles, all of which may contain some noncotton materials. Aggregation is easiest on a value basis (GATT uses this, see <sup>30</sup> and <sup>31</sup>), but annual variation may reflect price and mix changes more than volume would. Aggregation on a simple weight basis, as used by FAO (see <sup>23</sup>), requires conversion from numbers and yardage to weight. The most ideal means would be on a raw cotton equivalent (weight) basis, which would further consider the differences in manufacturing loss of various items.

<sup>3/</sup> The term "world cotton prices" generally refers to price quotations, c.i.f., Liverpool, England, or Bremen, Germany. Prices on these two large markets are taken to reflect world supply and demand conditions. These price quotations have two weaknesses: first, they are offering prices, and may differ from transaction prices; and second, the volume moving at the particular quotation is not known, permitting only simple averaging of prices. A separate quotation exists for each available growth and staple of cotton.

One practice in cotton price analysis is to take the price over time of a large volume growth--such as U.S. SM 1-1/16 inch, c.i.f., Liverpool--as reflecting changes in world price level. Another is to take an average of all or of several available quotations for a given staple length. This study used as a proxy for the world price of cotton an average of all but the highest quotation, c.i.f., Liverpool, of the following growths of SM 1 1/16; United States, Mexican, Iranian, Nicaraguan, Syrian, and Greek (see appendix table A-2).

## COTTON DEMAND OUTLOOK

The outlook for future cotton use depends upon population growth, income growth, the effect of income and other factors on per capita total fiber use, and the share of total fiber use that cotton can retain under intense competition.

### Population and Income Assumptions

#### Population Growth

Population projections for countries and regions as compiled by Moe (59) were accepted and used in this study. Basically, the projections are UN projections, with some adjustments based on studies by FAO, OECD, and USDA's long-term supply and demand studies. <sup>4/</sup>

The population projections for 1980 are presented in table 9. They show population growth between 1965 and 1980 at an average yearly rate of 1.0 percent in the developed sector, 1.8 in the central plan, and 2.6 in the less developed. Highest regional growth rates are indicated for Mexico, 3.6 percent; Syria, 3.5; and the UAR, 3.1. The lowest rates are projected for regions of Western Europe, 0.6 to 0.7; and for Eastern Europe and Japan, both 0.9 percent.

By 1980, the less developed sector will have about 50 percent of the world's population, up from 46 percent in 1965. In contrast, the developed regions will have 17 percent, down from 20 percent in 1965. The central plan proportion is expected to remain around one-third.

#### Income Growth

The income growth rates used in this study for the projection period were also those compiled by Moe (59). Again, principal sources were FAO and OECD projections, and the USDA's supply and demand studies.

The basic projections of total and per capita income for 1980 are presented in table 9. The projections represent consumer expenditure of the developed countries, net material product of the central plan countries, and the GNP of the less developed. On a per capita basis, income growth is projected at 3.4 percent per year for the central plan countries, 3.3 for the developed sector, and 2.1 for the less developed regions as a group. These projected rates are about the same as those which occurred during the 1950-65 period for the developed and less developed, but an improvement for the central plan, principally because of a higher expected growth rate in Communist Asia. Individual regions with high projected rates of increase in per capita income are Japan, 7.2 percent per year; the USSR, 4.4; Eastern Europe, 4.1; and the EC and Other Western Europe, 3.7. Lowest projected rates are for Other East Asia and Pacific (heavily influenced by Indonesia) at 0.9 percent per year, and Syria, 1.3 percent.

For direct projections involving world time series data, a 1965-80 rate of growth in world income per capita was roughly devised by weighting the regional income growth rates by the average 1965-80 population. These calculations indicated a growth rate of world per capita income of about 2.7 percent per year, compared with about 2.3 percent per year in the 1950-65 period (also determined by a weighting process).

---

<sup>4/</sup> These supply and demand studies are listed in Literature Cited.

1/ Consumer expenditure (1958 prices) in developed countries, net material product (1961-63 prices) in central plan countries, and GNP (1965 prices) in less developed countries.

Source: (59), except for revised (upward) population projections for India and Pakistan.

For the less developed regions, separate high and low income projections were generated. The high projections assumed substantial improvement over the past in agricultural and total economic growth, while the low projections assumed reduced rates of growth. <sup>5/</sup> Under the high assumptions, growth on a per capita basis for the LDC sector averages out to 3.9 percent per year, compared with the basic or medium projected rate of 2.1 percent. Under the low assumption, sector income per capita grows at only 0.7 percent per year.

#### Outlook for Per Capita Use of All Fiber

##### Trends in Per Capita Use

Per capita use of textile fibers (excluding flax and silk) has not increased equally in all regions. Use levels <sup>6/</sup> and (absolute) increases in use are considerably higher in most of the developed regions, Eastern Europe, and the USSR than in Communist Asia and the less developed sectors (table 10). The United States has by far the highest per capita use, followed by Australia and New Zealand, and Canada. Lowest levels of use are found in East and West Africa and Other East Asia and Pacific. <sup>7/</sup>

In the period from 1953 to 1967, per capita fiber use expanded most (in absolute amounts) in Australia and New Zealand, Japan, the United Kingdom, Eastern Europe, and the USSR. In the less developed regions, expansion was greatest in Other West Asia (mostly Israel), Iran, Turkey, South Korea, and Taiwan. Very little or no permanent improvement in use occurred in Communist Asia, most of South America, India, and Other East Asia and Pacific.

Absolute increases in per capita fiber use in the higher income countries (developed, Eastern Europe, and the USSR), especially Japan, have been very large. Most of the increase in the United States has occurred since 1964.

##### Factors Affecting Use

Major factors affecting trends in per capita fiber use are per capita income, fiber prices, fiber availability, and trade promotion. Climate may also have some influence.

Per capita income generally has more influence than other factors. Increases in per capita income go in part towards increased consumption of clothing and other items containing fibers (carpeting, automobiles, furniture, etc.). The regions with the largest increases in per capita fiber use have also generally had large increases in per capita incomes. Good examples are Japan, Iran, and Taiwan.

The relative magnitude of the response in fiber use to changes in income has been analyzed or estimated in other studies (see table 11). In general, these studies conclude that income has a positive but decreasing effect, i.e., a decreasing elasticity as per capita income increases. For very low income countries, they indicate that a given 1 percent increase in income results in a nearly equal percentage increase in per capita fiber use. For higher income countries, they indicate a response of less

---

<sup>5/</sup> The rationale and magnitude of the high and low projections are discussed in the overall study report.

<sup>6/</sup> Use is defined as availability, and thus changes in stocks are not accounted for. This distorts the Hong Kong figure considerably, and may affect other regions to a lesser extent.

<sup>7/</sup> Total fiber availability may be underestimated for these regions because trade in rags and used clothing is not considered.

1/ (47, pp. 16-33). The elasticities noted were calculated from the semilog equations. They were usually the same or very close to those based on log-log equations. 2/ (48). 3/ (16, vol. II, p. 67). Estimated from analysis of 1952-58 data. 4/ (21). Estimates based on econometric studies and judgment. Where two figures are given, lower refers to apparel use while higher refers to household use. 5/ (60, p. 60). Estimates based on time series, cross-section analysis, and judgment. 6/ Calculated from the coefficients of linear, semilog, and log-log equations fitted mostly to 1953-64 data. See discussion in appendix A and tables A-5 and A-6. W.S. means that the regression coefficient had a wrong (negative) sign. N.S. means regression coefficient was not statistically significant. 7/ E refers to accepted elasticity. 8/ (14, pp. 53-61). Based on multiple regressions on 1927-60 data. 9/ (13). France only. 10/ Greece only. 11/ Denmark only. 12/ For cotton yarn only, value based calculation. 13/ (32). Clothing only. 14/ (70, p. 36). 15/ Guatemala only. 16/ (65). All clothing expenditures, urban areas only. 17/ Argentina only. 18/ Uruguay only. 19/ Congo (K) only. 20/ (24, volume on Near East). Cotton only. Range is for countries within the region. 21/ Israel only. 22/ (61, p. 213). Lower figure is for rural areas. 23/ (2, p. 198). East Pakistan, cotton cloth only. 24/ Burma only. 25/ Indonesia only.

than 1 percent. In nearly all cases, the elasticities calculated or used in these studies were gross, in that the effects of other factors on per capita use were not held constant.

New analyses of the effects of income on fiber use were made in this study, using both time series and cross-sectional data. <sup>8/</sup> One significant conclusion of the analyses was that the gross response (income elasticity) of fiber use does not drop (or no longer drops) as countries or regions climb the economic ladder, except possibly for countries moving up from the lowest echelons. This, of course, contradicts the conclusions of previous studies. The explanation seems to be that factors other than per capita income per se are increasingly playing a role not only in the level of per capita use but also the response to changes in income. For example, restrictive trade policy and high prices may be dampening the response in some countries with low income levels. In countries with high income levels, factors such as lower manmade fiber prices and increased promotion could be stimulating the gross income response.

One income-connected factor not considered in the analysis, which may be of some importance, is distribution of income. Conceivably, the more highly concentrated a region's income is in the hands of a few, the lower would be both that region's per capita fiber use and the response to increases in income, other factors equal.

Prices of textile fibers, including cotton lint, have been trending downward. These lower prices have probably stimulated textile fiber use, particularly in the developed countries, in two ways: First, lower prices have very likely spurred the use of synthetic fibers in carpeting and in twine, burlap, netting, backing for rugs, etc. (substituting in the last-named products for jute, sisal, hemp, and other vegetable fibers not included in total fiber use). Second, lower raw material prices may have helped provide a margin for increased advertising and other promotion of end products.

Analysis of the relationship of prices to per capita use has generally not been attempted because of data problems. Although raw cotton prices are fairly available, prices of manmade fibers are not. In a few developed countries, wholesale list prices are quoted, but these are frequently deceptive because of off-list selling. <sup>9/</sup> Donald, et al, had some success in such an analysis (<sup>14</sup>, pp. 52-53). They found a 1 percent decrease in a weighted fiber price index associated with an 0.3 percent increase in U.S. per capita fiber use.

New analysis of price effects was attempted in this study, but with disappointing results. <sup>10/</sup> It proved impossible in most cases to obtain any significant or conclusive measurement of the separate effects of either cotton price or synthetic fiber price apart from that of income. <sup>11/</sup>

---

<sup>8/</sup> Details of the analytical results are discussed in appendix A.

<sup>9/</sup> For further discussion of the price problems, see appendix A.

<sup>10/</sup> See appendix A for details.

<sup>11/</sup> The ideal variable to have included as a proxy for the general level of fiber prices for each region would have been a weighted average price in which the price of each component fiber was weighted by its share of total fiber use. However, at most, this could be done on only a very gross basis, using a representative price for the numerous types of cotton, another for the various types of rayon, etc. The unavailability and frequent unreliability of manmade fiber prices, as well as the time involved in calculation, prohibited the use of such a weighted price in this study.

Fiber availability, in the absence of price setting, is reflected in prices. Import restrictions on raw fiber or textiles in the form of quotas, high tariffs, or Government buying have slowed expansion of fiber use in many less developed countries and Communist Asia. The policy behind the restrictions is, of course, the protection or stimulation of domestic industries and the conservation of foreign exchange. Developed countries also have import restrictions, but the effect on per capita fiber use quite likely has been much less because of the higher average incomes and the relative efficiency of domestic textile manufacture. <sup>12/</sup>

Modern promotion and modern communication is stimulating consumer desire for new and larger quantities of clothing, carpeting, automobiles, tires, furniture, and numerous articles containing fibers. This has been an important factor in the high responses to changes in income in the developed countries, as indicated in the analysis made for this study.

A generally cool or variable climate may stimulate clothing use over what it would otherwise be with a given income per capita. However, most countries with temperate climates are also more developed than tropical or semitropical countries, so that it is difficult to separate the effects of climate from those of income.

To measure the combined effect on fiber use of factors other than income and price, the initial time series analysis of this study included a time trend variable. However, income and time trend were so highly intercorrelated in most cases that time trend had to be eliminated to avoid confounding the income results.

#### Projections of Fiber Use to 1980

Two procedures were used to develop projections of per capita fiber use to 1980: (1) linear, semilog, and log-log equations developed in the time series analysis; and (2) log-log functions and assumed income elasticities.

Direct projections from time series equations were made for 24 of 33 regions, and for the developed sector and total world (table 12). <sup>13/</sup> The semilog equation, which assumes a decreasing income elasticity of fiber use, always produced the lowest projection. The highest projection was usually that of the linear equation, which assumes an increasing elasticity. The middle projection was usually that of the log-log equation, which assumes a constant income elasticity.

Some of the regional projections from the semilog and log-log equations appear reasonable. The semilog projections for the United States, Canada, the United Kingdom, and Japan are the most acceptable. For the EC, the projection from log-log equation appears the most reasonable.

Many of the projections from the linear equations are clearly unrealistic. For Japan, achievement of the linear projection would give her the world's highest per capita use, even above that of the United States. Although Japan's projected income growth rate is the world's highest, it will still have a lower per capita income in 1980 than all other developed regions except Other Western Europe and South Africa.

For the developed sector as a whole, the direct projections indicated lower per capita fiber use levels than did the weighted average of the regional projections. The

---

<sup>12/</sup> Trade restrictions are discussed in more detail in the sections on cotton textiles and cotton lint trade.

<sup>13/</sup> No direct projections were attempted for regions with low  $R^2$ 's, or with nonsignificant or negative income coefficients.

<sup>1/</sup> Projections are based mostly on extension of 1953-64 trends, since 1965-67 data were generally unavailable at time of analysis; see appendix D for implications. <sup>2/</sup> Unacceptable because of very low R<sup>2</sup> or negative income coefficients. See appendix A for R<sup>2</sup> values and details of analysis. <sup>3/</sup> 1964. <sup>4/</sup> Includes Peru.

Source: Table 11 and equations developed in time series analysis. See appendix A.

cause for this was a sector income elasticity (0.72 to 0.74) lower than most of the regional income elasticities (see table A-6 of appendix A). However, the high regional elasticities for the United States, the United Kingdom, Canada, and Australia and New Zealand, are probably biased upwards because of revised, more inclusive data in the later years of the time period. <sup>14/</sup> Thus, the sector elasticity and projections may be the most acceptable.

The direct projection of world per capita fiber use shows a 1980 figure of 6.4 to 6.9 kilograms, based on a mean income elasticity of 0.62.

Comparison with a weighted regional average use is not possible, either because no analysis could be made in some regions or because the equations were unacceptable.

Log-log projections under alternative elasticity and income level assumptions are presented in table 13. <sup>15/</sup> Again, these projections hold the income elasticity of fiber use constant through the projection period, an assumption suggested by the analytical results of this study. <sup>16/</sup>

Some of the log-log projections purposely equal or approximate the direct projections from semilog equations; elasticities for the log-log function were chosen arbitrarily to produce that result.

Elasticities from the time series analysis which appeared reasonable were used either for the high or medium elasticity projections. <sup>17/</sup> Elasticities for the United States, Canada, and the United Kingdom were dropped from unity or above to 0.8 and 0.7 for the high and medium projections, because of the probable upward bias in the higher figures. Elasticities were reduced to more reasonable levels for Communist Asia, the Sudan, Other South Asia, Hong Kong, and South Korea. For Communist Asia, an elasticity was selected which would increase fiber use per capita, using a log-log function, to about the same level as the late 1950's before use dropped off substantially. Any other assumption seemed out of line with what government policy in that country would allow. Elasticities based on those of surrounding regions and judgment factors were selected for Central America and Caribbean, Brazil, Other South America, East and West Africa, the UAR, Other North Africa, Other West Asia, Pakistan, Other South Asia, Hong Kong, and Other East Asia and Pacific.

Japan's estimated elasticity was the lowest for any region, below 0.5, simply because a figure as high as that of other developed regions, along with Japan's rapid expansion in per capita income, would shoot per capita fiber use to an unbelievable level.

For the developed sector, the weighted averages of high and medium elasticity--medium income projections are 19.9 and 19.0 kilograms per capita. The latter figure would represent absolute growth of 5.0 kilograms over 1965-67, a change which is greater in itself than the per capita levels of nearly all less developed countries. Nearly equal absolute (but higher relative) increases are indicated for Eastern Europe and the USSR.

---

<sup>14/</sup> See discussion in appendix A.

<sup>15/</sup>  $\log Y_{1980} = \log Y_{\text{base period}} + E_I(\log I_{1980} - \log I_{\text{base period}})$  where  $Y$  = per capita fiber use;  $E_I$  = income elasticity of per capita fiber use;  $I$  = per capita income, either actual or an index.

<sup>16/</sup> See appendix A.

<sup>17/</sup> The elasticities accepted for projection were noted previously in table 11.

1/ Log-log function used for projecting, see text for discussion. Elasticities used are shown in table 11. Base period for projecting was generally 1964 since 1965-67 data were not available at the time. In light of the new data, the projections are too low for several regions; notably Australia-New Zealand, East and West Africa, and Other West Asia; see appendix D for discussion.

2/ See table 10 for 1965-67 per capita use.

For the less developed sector, the high and medium elasticity--medium income projections are 3.3 and 3.2 kilograms. The change over 1965-67 would be some 0.6 to 0.7 kilograms. As small as this absolute increase is in comparison with that projected for the developed sector, it is large compared with LDC sector increases in the past.

With high income growth in the LDC sector, and assuming medium elasticity, the projections indicate that average per capita fiber use in the sector could reach 4 kilograms by 1980, an increase of 1.4 kilograms over 1965-67. Alternatively, a retardation in LDC income growth could limit the sector's per capita fiber use increase to 0.2 kilograms, reaching only 2.8 kilograms by 1980.

Per capita use of fibers in 1980 will probably be highest in the United States, with Japan possibly moving above the United Kingdom for second highest. Lowest use will continue to be in East and West Africa, and in the Asian regions.

#### Conclusions on Outlook for Fiber Use

Per capita use.--The log-log projections based on the medium elasticity and medium income growth assumptions are accepted as the most likely. These projections average out to a world per capita use in 1980 of about 6.8 kilograms, about the same as that indicated by the direct projection of world per capita use, based on a log-log time series equation.

Less likely, but possible, if either income growth should improve markedly in the LDC sector or elasticities should be higher, there would be a world per capita use of over 7 kilograms. A dropping off in LDC income growth, could restrict world use in 1980 to some 6.6 kilograms per capita.

The accepted medium projections are generally above those for 1980 published by the National Advisory Commission on Food and Fiber (appendix table C-1). In that study, world per capita use was projected at 6.4 kilograms or 0.4 kilograms less than that accepted here. This study's accepted projections are higher because of higher assumed elasticities in the developed and central plan regions, and slightly higher income growth rates in the less developed sector.

Total fiber use.--Multiplying the accepted per capita use projections by projected 1980 population (4,541.7 million worldwide) indicates a total world fiber use in 1980 of 31 million metric tons, compared with 17 million metric tons in 1964 and about 19 million metric tons in 1967. The 31 million metric tons would be distributed approximately as follows:

	Million metric tons	Percent 1980	Percent 1964
Developed. . . .	14.9	48	51
Central plan . .	8.8	28	27
Less developed .	<u>7.3</u>	<u>24</u>	<u>22</u>
	31.0	100	100

The projections indicate that an increasing proportion of world fiber use will occur in the less developed regions because of higher population growth, with a decreasing proportion mainly in the developed regions.

Higher elasticities in all sectors or high income growth rates in LDC's would boost total world fiber use in 1980 to over 32 million metric tons or, if both occurred, up to nearly 34 million metric tons. If income growth were to drop off in the LDC's, world fiber use in 1980 might not exceed 30 million metric tons.

## Outlook for Cotton's Share

### Trends in Cotton's Share

Cotton's share has been trending downward in about four-fifths of the regions established in this study (table 14). Surprisingly, the largest decreases in share between 1953 and 1967 occurred in less developed countries: Taiwan, Iran, South Korea, and South East Asia, all with drops of 16 to 36 percentage points. Decreases of 14 to 17 percentage points occurred in the USSR, Peru, Other North Africa, the United States, and the EC.

Regions in which cotton use increased as a percentage of total fiber use were Hong Kong <sup>18/</sup>, Syria, the Sudan, Colombia, the UAR, and Central America.

### Factors Affecting Cotton's Share

The major factors affecting cotton's share of total fiber use are price competition among fibers, domestic availability of cotton versus manmade fibers, physical differences among fibers, and extent of promotion.

Prices of cotton and competing fibers are the factors most influencing cotton's share of total fiber use. An increase in the price of cotton--other prices and factors remaining constant--or a decrease in the price of competing fibers relative to cotton could be expected to affect a decrease in cotton's share and, in turn, in per capita cotton use over what it would otherwise be.

Rayon and polyester staple are the fibers most intensely competitive with cotton. Wholesale list prices of these two fibers, as available in a few countries, have been trending downward. <sup>19/</sup> The decreases in rayon prices have corresponded with those of cotton. However, the decreases in polyester prices have been relatively greater than those of cotton, particularly in recent years. In the United States, the cotton/polyester price ratio increased from 0.24 in 1952 to 0.38 in 1965 and then to 0.62 in 1967 (see appendix table A-3).

List prices of manmade fibers (including both polyester and rayon) are sometimes deceptive because of discounting or off-list selling. In the United States, for example, actual prices of branded polyester fiber during January 1969 were reportedly some 10 cents per pound below the list price of 61 cents (52, p. 6). Prices of unbranded fibers were reported to be below 40 cents per pound. Regular rayon listed in early 1969 at 28 cents per pound was reportedly available at around 25 cents per pound.

Discount prices of particular manmade fibers vary according to competitive conditions, including the level of cotton prices, even though the list price remains the

---

<sup>18/</sup> Estimate for cotton's share in Hong Kong may not be accurate because of large stocks for export.

<sup>19/</sup> List prices are available on some fibers for most highly developed countries, but series are frequently incomplete, noncomparable, or deceptive because of off-list selling. The prices used here were compiled by FAS/USDA largely from Skinner's Record, a British publication which ceased to publish such international price series in September 1966 because of (paraphrased) the vastly increased number of fiber producers, complexity of fiber types and brands, and introduction of different price scales (see Sept. 1966 issue of Skinner's Record).

same. <sup>20/</sup> This is particularly so for rayon prices. Neither the extent or duration of the discounts are reported systematically. <sup>21/</sup>

The outlook for long-run changes in price levels, which the list prices roughly depict, is for little real change in rayon prices and continuing declines in real polyester prices. Rayon has apparently about achieved available economies of scale in production, given present and foreseeable technology. The leveling out of the rayon list prices in recent years suggest this, although a rather major factor has been the leveling out of world cotton prices. Recently, an increase in U.S. rayon list prices (in current dollars) has occurred, suggesting inflationary pressures and tightening margins.

The downward trend in real polyester prices occurring in countries with available data showed no leveling off as of 1964-67 (fig. 2). More recent data, when available, will probably show some slackening in the rate of price decline in the United States and the United Kingdom, such as occurred in the case of nylon prices in the United States beginning in the early 1960's. In the United States and the United Kingdom, a continuation of this drop would result in polyester list prices under 20 cents per pound by the late 1970's--an improbability. According to the International Cotton Advisory Committee, (ICAC) reductions in real price may result from increases in production capacity and additional research and development efforts (52, p. 7). The ICAC also notes that profit margins on many manmade fibers have already declined significantly with the result that producers will find it necessary to increase production and sales to maintain profit levels.

A subjective guess as to what may happen to polyester list prices in the 1970's is depicted in figure 2. It is expected that list prices in major manufacturing areas will continue declining but at a lessening rate, leveling off at around 38-40 cents (1968 constant prices) by the late 1970's. Again, these are projected wholesale list prices; actual wholesale prices could be from 5 to 10 cents below these.

A further element involved in price competition should also be mentioned. Cotton prices have been more unstable than prices of competing fibers because of fluctuating supply (caused by weather conditions and government policies), textile inventory cycles, and other factors. This situation may have contributed to the conversion of mills from cotton to manmade fibers in some countries. Supplies of manmade fibers are more certain and prices more predictable.

Domestic availability is sometimes a crucial factor in less developed countries. The increases in cotton's share between 1953 and 1964 which occurred in Hong Kong, Syria, the Sudan, Colombia, the UAR, Central America, and Turkey were the result of installation of cotton textile mills as a part of industrialization. Import protection has usually accompanied mill installation.

Cotton textile mills appeal to some less developed countries because cotton is often produced domestically, whereas manmade fibers must still be imported, or produced locally on a high cost basis unless large volumes can be achieved.

Future expansion in cotton textile production in Africa, South East Asia, Other East Asia and Pacific (Indonesia, Malaysia, and Philippines), and Other West Asia will help maintain cotton's share in these regions over what would otherwise be the case.

---

<sup>20/</sup> For example, see (44, p. 9, 52).

<sup>21/</sup> Because of the inavailability and discounting problems, analysis of cotton use involving prices of competing fibers usually has not been undertaken in the past or has proved inconclusive (8, p. 25, 14, 52, p. 8).

## Figure 2. LIST PRICES OF POLYESTER STAPLE FIBER, SELECTED REGIONS, 1952-1967 AND PROJECTIONS TO 1980

(Prices in Constant 1968 Currency)

Source: Table A-3

However, manmade fiber production is also expanding in some LDC's (e.g., Mexico, Peru, Colombia). Cotton's share in these regions will drop at a faster rate in the future than in the past.

Physical differences have both positive and negative effects on cotton's share. Manmade fibers generally have greater strength and durability than cotton, while cotton has greater absorbency (and thus coolness) and softness or comfort.

The introduction of the wash-and-wear and permanent press processes has favored manmade fibers. Consumers in high income countries are increasingly purchasing these convenient, time-saving textiles (promotion as well as income is a factor here), even though they sacrifice some coolness and softness. The permanent press process, although it requires cotton to absorb the chemical, so weakens the cotton fibers that a 100-percent cotton fabric is not sufficiently durable for consumer acceptance. Manmade fibers are blended in to strengthen the fabric.

Although the prices of permanent press fabrics have generally been higher than nonpermanent press items, the consumer response has been great and a key factor in recent decreases in cotton's share. This has been particularly so in the United States and is becoming so in other developed countries and some less developed.

Efforts to develop a 100-percent cotton permanent press fabric continue. However, considerably more funds have gone into research and development of the manmades. Although this is likely to continue, cotton interests have stepped up their efforts. The International Institute for Cotton (IIC) is increasingly undertaking or financing research and development efforts with funds received from cotton producers in many countries.

Promotion is rapidly becoming a key factor in fiber competition. Advertising played an important role in making manmade fibers acceptable to consumers, and manmade fiber producers still expend many times more funds on advertising than cotton producers do. They frequently influenced the fabric blend ratio by subsidizing the promotional efforts of clothing manufacturers.

Promotion to date has not been as important in less developed and central plan countries as in developed countries. However, it will certainly be a major factor along with price and availability in future decreases in cotton's share in many less developed areas (e.g., Mexico, South America, South Korea, Taiwan, and Hong Kong).

#### Projections of Cotton's Share

Time trend projections.--Significant time trends of the historical period were extended to 1980 using two equations: linear and semilog. <sup>22/</sup> The linear projection shows what would happen if cotton's share continued dropping in the same absolute average yearly amount as in the historical period. The semilog projection permits a decrease in the yearly absolute amount of change over time.

About two-thirds of the regions had statistically significant downward time trends in the historical period. Extension of these trends to 1980 indicates large decreases in cotton's share from 1967 for the United States, the USSR, Communist Asia, Canada, Peru, Taiwan, Brazil, and Other South America.

Similar time trend projections made for the developed sector showed cotton's share dropping from 49 percent in 1965-67 to 37-40 percent in 1980. These projections come

---

<sup>22/</sup> For  $R^2$  values and significance of trends, see appendix table A-8.

out slightly higher than the weighted averages of the regional time trend projections. No sector projections were made for the central plan countries because of the economic diversity of the included countries. For the less developed sector, the historical trend was too weak for projection.

Projections at different price levels.--One set of projections of cotton's share in 1980 was made with equations using the difference (D) between projected prices for cotton and those for competing fibers. World cotton price in 1980 was set at levels ranging from 24 to 30 cents per pound. <sup>23/</sup> Synthetic fiber price was lowered to 40 cents per pound, wholesale list.

Another set of projections made from the equations involving the ratio (R) of cotton to synthetic fiber price were generally somewhat lower than those involving price difference (D) (table 15). <sup>24/</sup> In most cases, the price ratio projections seemed unrealistically low; two were negative, while others were in the 4 to 20 percent share range.

The accepted projections for most regions were arrived at by selecting from the alternative projections the one which seemed most reasonable under the particular price assumption. However, for those regions with upward, level, or nonsignificant trends in the historical period, projections were made simply from available information on likely direction and magnitude of share changes.

A lowering of world cotton price from 30 to 24 cents per pound in the price difference equations tended to increase cotton's projected share for 1980 by 1 to 2 percentage points. <sup>25/</sup> In the price ratio equations, share increased much more, up to 10 points. The latter increase seemed unreasonable in lieu of the promotional and product differences, so the former range was accepted. Even small changes in share for several regions add up to important increases in world cotton use.

By 1980, cotton's shares of fiber use in the various developed regions will range from 30 up to 42 percent, depending on the region and price assumption, compared with 42 to over 50 percent in 1965-67 (table 15). For the developed sector as a whole, cotton's share is projected to drop to 33-35 percent by 1980, or 14 to 16 percentage points below the 1965-67 level.

In the central plan regions, cotton's share in 1980 is expected to range from 36-37 percent in Eastern Europe up to 75 percent in Communist Asia. This will be down from 46 and 92 percent, respectively, in 1965-67. For the central plan sector as a whole, the projected drop in share will be from 69 percent in 1965-67 to 54 percent in 1980. Lower world cotton prices probably will not affect cotton's share in the USSR and Communist Asia because of central planning and barter trade.

Cotton's share can also be expected to drop rather sharply in many LDC's. By 1980, the projections show cotton's share ranging from around 35-37 percent in Other North Africa up to 80 percent in India, Pakistan, and the UAR. In 1965-67, the range among the LDC's was from 46 percent to 92 percent. For the less developed sector as a whole, the expected drop in cotton's share will be from 76 percent in 1967 to 66-68 percent in 1980.

---

<sup>23/</sup> Thirty cents was about the 1965-68 average for SM 1-1/16 inch cotton, c.i.f., Liverpool (appendix table A-2).

<sup>24/</sup> Statistical results of the time series equation are presented in appendix table A-8.

<sup>25/</sup> See appendix table A-9.

1/ Projections are based mostly on analysis of 1953-64 data, since 1965-67 data were generally unavailable at the time; see appendix D for implications. Time trend refers to extension of simple trend to 1980. Lower figure is linear trend, while upper is semilog (time logged) trend. Cotton price refers to price of SM 1-1/16 inch, Liverpool, in constant 1968 currency. The "D" projections are based on price difference between polyester and cotton, while the "R" projections are based on ratio of cotton to polyester price. Polyester list price in 1980 is assumed to be 40¢/pound. For details of equations and statistical results, see appendix table A-8. 2/ Based in part on time series analysis (see appendix table A-9). 3/ Based on price of cotton only, rather than price difference or price ratio. 4/ 1964. 5/ Includes Peru. 6/ These projections are too high in light of more recent data; 63-65 percent share in 1980 now appears more realistic, which would be 4-6 percentage points below the 1965-67 average.

Source: 1965-67 share is calculated from FAO data (25).

Worldwide, cotton's share in 1980 is projected at 47-48 percent, compared with 60 percent in 1967. The 47-48 percent is just below the 49-percent share indicated by the linear time trend projection.

The "accepted" projections of cotton's share in 1980 are generally lower than those arrived at in the NACFF study published in 1967 (appendix C-1). The differences range from 3 to 7 percentage points for the three sectors and 4-5 points for the entire world. The use of slightly more recent data and the outlook for a more rapid than then expected increase in manmade fiber use account for most of the differences.

#### Outlook for Cotton Use

##### Trends in Per Capita Cotton Use

Per capita cotton use has been increasing in most of the regions, the exceptions being the United States, Communist Asia, Brazil, Other South America, Other North Africa, India, Taiwan, and Other East Asia (table 16). As noted previously, cotton's decreasing share was the major problem in the United States and Other North Africa, while low income and per capita total fiber growth joined in to bring about the drop in the other regions.

Between 1953 and 1965-67, each of the sectors showed an expansion in average per capita use of between 0.2 and 0.4 kilograms. The largest increase was in the developed sector, while the smallest was in the less developed.

##### Projections of Per Capita Cotton Use

Projected per capita cotton use in 1980 was obtained by multiplying projected per capita total fiber use by cotton's projected share. The results are presented in table 16. The medium projections are the most likely.

Medium projections.--For the world as a whole, per capita cotton use in 1980 is projected at 3.2-3.3 kilograms, with world price at 30-24 cents per pound, and medium income growth and medium income elasticities. At the 24-cent price, projected use of 3.3 kilograms would be slightly above the 1967 level. At a 30-cent price, projected use would be slightly below the 1967 level. Per capita use in the developed sector is projected to decrease over 1967 use while that in the central plan and less developed sectors will increase.

Of the 33 regions, the projections show 21 with higher per capita use in 1980 than in 1967, and 9 with lower. The largest increases in per capita cotton use are projected for Hong Kong <sup>26/</sup>, Japan, Other Western Europe, Eastern Europe, and Turkey. The largest decreases are projected for the United States, Canada, and Australia-New Zealand.

Direct projections of per capita fiber use in 1980 were also attempted for the developed and less developed sectors and the total world (appendix table C-2). The statistical results were good only for the less developed sector. For this region, the direct projections indicated a per capita use of 2.3-2.4 kilograms, compared with the accepted 2.1-2.2 kilograms. The lower accepted projections result from a greater expected decrease in cotton's share in some LDC's than is indicated by historical trends.

Alternative projections.--Per capita cotton use in the LDC sector would increase substantially under the high LDC income growth rate assumption (table 16). Use could

---

<sup>26/</sup> The change in Hong Kong is probably overstated. Large year-to-year fluctuations in stocks make Hong Kong's consumption extremely difficult to estimate.

1/ 1952-54 average for individual country regions. 2/ Lower figure in the range assumes an average price for SM 1-1/16 inch cotton, c.i.f., Liverpool, of 30¢/pound; while the higher figures assume a price of 24 cents. Where no range is shown, change in projected per capita use was less than 0.05 kilograms. Some of the regional projections now appear low in light of improved 1965-67 data not available at the time; see appendix D. 3/ 1964. 4/ 1964-1980. 5/ Includes Peru.

Sources: Historical figures are calculated from FAO total cotton use data (15, 19, 23, 25), except 1953 U.S. figures are USDA. Projections are based on medium elasticity projections of per capita fiber use and projected cotton's share.

reach 2.7-2.8 kilograms, compared with the medium projections of 2.1 to 2.2. Average world use would also be greater, possibly by 0.3 kilograms per capita. Alternatively, low LDC income growth would lower both LDC and world average cotton use to or below 1965-67 levels.

#### Trends in Total Cotton Use

Total domestic end use of cotton has been increasing in all the regions delineated in this study, even those with decreases in per capita use (table 17). Expansion has been greatest in the less developed sector, as evidenced by its increasing share of world cotton use--28 percent in 1967, compared with 26 percent in 1953. The lowest expansion occurred in the developed sector.

#### Projections of 1980 Total Cotton Use

Projections of total domestic cotton end use in 1980 were made by multiplying each region's projected per capita use at alternative prices by projected population. The results are presented in table 17.

Medium projections.--Under the medium income assumptions, world use in 1980 is projected to range from about 14.6 to nearly 15 million metric tons, depending on the level of world cotton prices, compared with around 11 million tons in 1965-67. (In terms of bales, the projections indicate 67 to 69 million, compared with about 52 million in 1965-67). Nearly half of projected expansion in world cotton use will take place in the less developed sector, with its share projected to increase to 33 percent by 1980, up from 28 percent in 1967. The least expansion will occur in the developed sector, with a substantial decrease from 1967 projected in share of world use.

The projections indicate that total cotton use will continue increasing in all regions, except for possibly the United States, Canada, the United Kingdom, and Australia-New Zealand, if world cotton price should climb back to the 30-cent level of 1965-67. With prices declining to 26 cents, some expansion in total use is projected even for these countries, except for Canada.

At a 26-cent world cotton price, the greatest increases in total domestic cotton use are projected for Communist Asia, India, the USSR, Japan, the EC, Eastern Europe, and Pakistan.

The projected effect of world price on total domestic cotton use differed by sectors, with the least effect likely in the central plan sector because of government intervention. The projections indicate that a 1-cent decrease in price will result over the long run in an average increase in total cotton use of about 40,000 metric tons in the developed sector, 3,000 in the central plan, 25,000 in the less developed, and 68,000 metric tons worldwide.

Alternative projections.--Total cotton use in 1980 would differ somewhat from the projected 14.8 million metric tons at the 26-cent price if income growth rates should be higher or lower than the medium assumptions. Higher income growth in the less developed sector could raise projected world use to 16.1 million metric tons. A sizable deterioration in LDC's income growth could lower projected world use to around 14.2 million metric tons.

## COTTON SUPPLY OUTLOOK

### Production Situation and Trends

In recent years, about 45 percent of the world's cotton has been produced in less developed countries, 32 percent in central plan areas, and 23 percent in the developed sector (table 18).

The world's largest producer is the United States, with one-fifth of total world production in 1965-67 (table 18). The USSR is the second largest, with about 18 percent of world production. Mainland China ranks third and India fourth. Brazil has recently pushed ahead of Mexico for fifth position. Others, in order, are the United Arab Republic, Pakistan, Turkey, the Sudan, Syria, and Iran.

Regions showing the highest absolute increases in production over the last decade have been the USSR, Turkey, Brazil, Central America, India, Pakistan, the UAR, and the Sudan. Other regions with high relative increases have been Australia, Colombia, and Greece. Recent production has been below levels of a decade ago in the United States, Argentina, and Eastern Europe.

Both cotton area and yields have been increasing in most of the producing countries of the world (table 19). In absolute terms, the greatest area expansion has taken place in Tropical (East and West) Africa <sup>27/</sup>, Brazil, the USSR, the Sudan, Pakistan, and Central America (in that order). Significant expansion has also occurred in South East Asia, Colombia, and Iran. Large decreases in area occurred between 1955 and 1967 in the United States, Communist Asia (mostly Mainland China), Mexico, and Other South America (mostly Argentina).

Increase in yield has been phenomenal in Australia; the absolute increase itself being higher than the average yield of most other countries. <sup>28/</sup> Regions with less spectacular, but sizable yield increases were Turkey, Other West Asia, Other Western Europe, and Central America.

India has by far the largest area in cotton of any country, nearly 20 million acres, but its yields are among the lowest in the world. Mainland China has the second largest acreage, over 12 million, but with better yields. The United States is third in acreage, but first in production because of much higher yields.

Australian cotton yields averaged over 900 pounds per acre in 1965-67. The next highest yield shown--727 pounds per acre--occurred in the USSR, but Soviet cotton acreage is over 100 times that of Australia. Other regions with average yields over 600 pounds per acre were Central America and Mexico. Lowest yields occurred in Other East Asia and Pacific, India, East and West Africa, and South East Asia.

---

<sup>27/</sup> Area statistics for Tropical African countries are not considered reliable, so those used here must be considered only an order of magnitude.

<sup>28/</sup> Australia began subsidizing cotton production in the early 1960's. The subsidies attracted new farmers, many of them American. There was an increase in acreage, a shift to irrigated land, the introduction of new techniques and the resulting phenomenal yield increase.

Table 18.--Cotton production in 1965-67 and change over 1955-57

### Factors Affecting Production Trends

Factors which affect trends in cotton production are: (1) world cotton prices; (2) government intervention in production, marketing, and prices; (3) comparative advantage; (4) land availability; and (5) technological change. <sup>29/</sup>

World cotton prices.--Prices in major importing markets have been trending downward because world supply has been increasing faster than demand. The outlook is for further decreases in the future (see projection sections).

Declining price has had and will continue to have the effect of dampening world production from what it otherwise would be. When other affecting factors are held constant, price and cotton production are positively correlated.

The net response of acreage or production to changes in price has been the subject of other studies (table 20). The elasticity coefficients encountered have generally fallen in the 0.2 to 2.5 range (production or acreage changes by 0.2 to 2.5 percent for each 1-percent change in price), depending upon the region or country, the time period, and whether the price series used was world or domestic.

Government intervention frequently modifies the extent to which domestic prices reflect the world price situation. An example is the USSR, where the government recently raised domestic prices to stimulate production, even though world prices were trending downward. Also, in the UAR the government sets both prices and the area seeded, with the goal of maximizing foreign exchange earnings. In still other countries, prices are supported and imports restricted to stimulate domestic production and conserve foreign exchange. The United States uses price supports and import restrictions to increase producer returns.

The outlook is for more rather than less intervention. As brought out in the Introduction, export earnings from cotton are extremely important to many LDC's. The inclination will be to assure continuance of such earnings unless the land can be put into other export-earning or import substitution crops.

Comparative advantage.--Many factors enter into the determination of comparative advantage in cotton production. Production costs and returns are the most easily measurable indicators. But the availability of alternative land uses, the location of producing countries, processing costs, and product quality are equally important determinants.

Until recently, little information was available on comparative costs and profitability of growing cotton in the major competing countries. The Foreign Agricultural Service (FAS) of the U.S. Department of Agriculture is now investigating this subject in visits to foreign producing countries. Some roughly comparable information has already been gathered in Brazil, Mexico, Central America, Pakistan, and Iran.

South Brazil, Pakistan, Guatemala, and Iran appear to have both a total and direct cost advantage over Mexico, the United States, and El Salvador (table 21). <sup>30/</sup> Returns

---

<sup>29/</sup> A general discussion of these factors is given here. For more specific details on factors (2) to (5) for the various regions, see appendix B.

<sup>30/</sup> Total cost includes land rental, whereas direct cost does not. Direct costs are believed to be the better indicators of short-run production incentives, except in those cases where cotton is grown on rented land by persons whose main interests lie outside of agriculture.

Source: U.S. data are from 1966 Supplement to Costs of Producing Cotton in the United States, Agr. Econ. Report No. 99, except figures are adjusted to a net weight, prior growing basis, to be comparable with the foreign data. The foreign data are USDA/FAS, except figures in parentheses are derived from original FAS estimates and revised data on yields (41; 42; p.4, 73).

per pound of cotton and per acre appeared to be the highest in the United States (when allotment payments are included) and Central America, lower in Iran, Pakistan, and South Brazil, and lowest in Mexico. However, the U.S. advantage in profitability would disappear if the allotment payments were withdrawn. There is slight subsidization of cotton production in some foreign countries through credit terms, input prices, etc., but probably not enough to alter the picture. Adequate data are not available on production costs in other countries, but most observers characterize Greece, Australia, South Africa, Colombia, Peru, and Syria as relatively high-cost producers; while Tropical African countries and Turkey are low-cost producers.

Alternative land use is another important component of comparative advantage. If cotton is the most profitable crop within a given producing area, it is not likely to be replaced, regardless of how production costs compare with those of other areas. In parts of South Brazil, cotton holds an economic advantage over both peanuts and corn, the major competing crops (64). It also has a strong comparative advantage over crops for the use of the considerable amount of newly cleared land available in most years. In Central America, farmers who obtain good yields with reasonable production efficiency find cotton much more profitable than alternative products (40). In both Pakistan and Iran, farmers look upon cotton as a sure, profitable crop, and acreage has been expanding despite declining world cotton prices (42). In Mexico, high yielding land will give profitable returns at the present or even lower prices (41). In the UAR, the profitability of cotton is above that of sugarcane, and considerably above that of grains and oilseeds (75). In the Sudan, the profitability of cotton is more than double that of any other major crop (75, p. 32). In some countries, where no alternative export crops have been developed, cotton holds an advantage just because it has an export market.

A further factor in the competition between cotton and alternative crops is the institutionalization of cotton production. Production loans, credit extension for fertilizer, etc., is frequently more available for cotton than for other crops because of the marketability of the product. This is changing as communications improve and marketing channels for other products build up, but it still causes farmers in many areas to plant cotton when other crops could be as profitable.

The location of cotton-producing countries is a determinant of comparative advantage. Exporters near major importing areas, or with cotton-producing regions near their points of embarkation have advantages over other exporters. In these respects, cotton exporters of the Mediterranean area, like Egypt, Syria, Turkey, and Greece, are likely to have a transport cost advantage in European markets not enjoyed by more distant producers. Countries with poor or difficult transport facilities for exports (Afghanistan and Chad are extreme examples) suffer a disadvantage, compared with countries whose cotton is grown nearer to their ports.

Processing costs, particularly ginning, can be a determinant of comparative advantage. As table 22 shows, ginning costs vary widely from country to country. These costs can make a 1- or 2-cent difference in the cost per pound of cotton.

Countries that produce higher quality cotton (e.g., longer staple and higher grade) benefit from higher export prices. Egypt, the Sudan, and Peru, in particular, benefit from higher world prices for long and extra-long staple cottons, but their growing costs are also somewhat higher. Handpicked cotton is usually cleaner (higher grade) than machine-picked cotton. Grade of cotton is also affected by soil types, rainfall, defoliation methods, temperature, insect damage, ginning methods, storage, and transportation.

Comparative advantage also underlies shifts in area within countries and among producers. Such shifts have been responsible for a sizable part of the increase in average yields in many countries. Shifts occur most rapidly in times of dropping prices and absence of government programs and price intervention.

Source: Vernon L. Harness. "Comparison of U.S. and Foreign Cotton Ginning." Foreign Agriculture, Jan. 19, 1970.

Land availability.--Cotton acreage and production have expanded during the last decade in Australia, Brazil, Central America, and Colombia because of new lands coming into cultivation and/or under irrigation. In Mexico, cotton acreage has moved into new areas, and much of the old cotton acreage has been turned over to competing crops. In the Sudan, and to a lesser extent in Australia, most of the cotton cropland expansion was into newly irrigated arid lands. The expansion in Brazil, Central America, and Colombia was principally into previously underutilized pastureland. Considerable amounts of new land suitable for cotton production remain in Australia, Brazil, other Latin American countries, the Sudan, many Tropical African countries, the USSR, and elsewhere. Some of this available land, particularly in Australia, the Sudan, and the USSR, would require irrigation before it could be brought under cotton cultivation.

Technological change, particularly as it affects yields and production efficiency, has great potential in many producing countries. Central America has had severe problems with insect control which, along with inefficient use of insecticides, raised costs. This is now being corrected, farm sizes are getting larger and, in general, production efficiency is increasing (73). In South Brazil, cotton is now considered a permanent rather than a transition crop and efforts are underway to increase yields through improved soil fertility, insecticide application, and better seed (64). Other areas, like India, Pakistan, and Tropical Africa, with relatively inefficient production methods, can be expected to make technological advances during the 1970's. These changes will be principally in the area of better seeds, improved cultivating practices, and the use of some modern inputs, especially insecticides.

In Pakistan, India, Mainland China, and several African countries, considerable potential exists for improving presently low yields. Progress has been slow to date, but the demonstration effect of the "Green Revolution" may considerably change farmer attitudes and adaptive practices. Use of improved cotton varieties could greatly increase yields in some areas. In Iran, yields are improving with advances in reclamation, irrigation, and insecticide use. As yet, little fertilizer is used, so considerable potential exists here.

#### Statistical Analysis

Time and resource limitations of this study did not permit extensive new statistical analysis of the factors affecting cotton supply in the various regions to use as input for projections. However, analysis to provide some guidelines was made of 1955-69 time series data on area, yield, and production for the following sectors: foreign developed (excluding the United States), central plan, less developed, and foreign world. The equations fitted and statistical results are summarized in table 23.

The regressions were generally better (higher  $R^2$  values and higher levels of significance of coefficients) for yields and production than for area. However, acceptable results for area were obtained for the less developed sector and for total foreign world. The statistical results of the linear and semilog equations provided no basis for choosing one over the other.

The price of cotton had a significant and positive relationship with both area and yields in the less developed sector, with yields in the foreign developed sector, and with area in the total foreign world. <sup>31/</sup> For the less developed sector, the elasticities of response to price were 0.19 to 0.23 for acreage, about 0.21 for yields, and 0.32 to 0.46 for production. The higher elasticity of production than of acreage

---

<sup>31/</sup> Cotton price used in all cases was the average Liverpool price of SM 1-1/16 inch cotton, lead 1 year and deflated to constant 1968 currency (see appendix table A-2).

1/ In the equations: Y = area, yield, or production; T = time; and P = price of SM 1-1/16 inch cotton, Liverpool, deflated and led 1 year (see appendix table A-2). Time series analysis covered period 1955-69. 2/ n.s. means regression coefficient not significant.

Source: Time series data were FAS/USDA.

reflects the effect of price on yields, suggesting that area response is generally greater in regions where yields are also more responsive to price, or that area response is greater in those regions where yields are higher. For the foreign world, the area response to price changes was near 0.23. The insignificance of the price variable in the central plan sector is evidence of a high level of government intervention in domestic pricing and production planning.

#### Regional Price Elasticities

Estimated long-run responses of acreage in various countries and regions to change in world price levels are presented in table 24. These responses are based on the statistical analysis of the major sectors just discussed, on the statistical analysis performed by others (see previous discussion and table 20), and on judgments derived from reports by USDA personnel traveling or stationed in the various countries. Again, the time and scope limitations of this study did not permit extensive new statistical analysis on regional supply.

The highest area responses are estimated for Mexico and Central America, both at 1.5, and for Colombia, South Brazil, Peru, Turkey, and Syria, at 0.6 to 1.0. Price is not expected to influence area in the central plan countries because of government intervention or in India because of high domestic use. It is likely that price will only marginally affect area in Africa, North Brazil, and in many Asian producing countries because of low costs, protected markets, or few alternative crops of similar profitability.

If yields are fairly homogeneous among producing areas, the response of production to change in price is the same as that of acreage. However, if the acreage response occurs primarily in areas of high yields relative to the average yield of all areas, the production response would be higher than the acreage response.

It may be valid to assume homogeneous yields within certain countries, but it cannot be valid to do so for large aggregates of countries, such as the less developed world where average yields vary greatly among countries.

Higher production responses frequently occur in areas with higher yields, such as Central America, Mexico, and Turkey. Thus, the result of a 1-percent drop in world price would be an aggregate decrease of 0.46 percent in production in LDC's, compared with a 0.25-percent decrease in acreage (table 24). Such a divergence would hold for the foreign free world as a whole, because of the importance of less developed producing countries. For the developed foreign producing countries, the aggregate coefficients came out to be 0.27 for acreage and 0.26 for production.

#### Projections of Production in 1980

Direct projections of foreign sector and world area, yields and production for 1980 were made by extension of the equations (with significant coefficients) developed in the time series analysis (table 25). In the multiple equations, world price for 1980 was set at levels ranging from 24 to 30 cents per pound for SM 1-1/16 inch cotton, c.i.f., Liverpool (in constant 1968 currency).

The linear projections always came out higher than the semilog, because of the upward trends and because the former function assumes that the average (absolute) rate of increase in the historical period will continue through 1980, while the latter

Table 24.--Estimated long-run responses of cotton acreage in foreign producing countries and regions to changes in world price levels, projection period of 1970-80

Country or region	Estimated price elasticity	Comments 1/
<u>Developed</u>		
Western Europe . . . .	0.3	In Greece, government policies (high subsidies and production goals) isolate producers from world price levels. However, high production costs and importance of exports permit some price responsiveness. In Spain, growers produce for a protected home market, but the increasing importance of imports allows price to play some role.
Australia & South Africa	0.1	Low response because production is for a protected domestic market.
Weighted average 2/.	0.27 for acreage; 0.26 for production	
<u>Central Plan</u>		
USSR . . . . .	0.0	Government sets the price independently of world prices. The growers, however, are very responsive (E = 1.0 to 2.0) to prices set by the government.
Eastern Europe . . . .	0.0	Production is very minor and isolated from world prices.
Mainland China . . . .	0.0	Production entirely for domestic market, which is isolated from international prices. Cotton imports are not an alternative to domestic supply.
Weighted average . .	0.0	
<u>Less Developed</u>		
Mexico . . . . .	1.5	Based in part upon FAS unpublished analysis. Mexico is a relatively high cost producer. Average price for lint (before ginning) was 23.7¢ in 1969/70. Direct cost of production (weighted average) was 22.5¢ per pound and total cost 25.5¢. There are several alternatives to cotton production.
Central America. . . .	1.5	Based in part upon FAS unpublished analysis. Central America is a high cost area. About 90% of production is exported. Weighted average costs for the region (67/68) are approximately 20.2¢ per pound direct and 26.0¢ total. The average farm price in 1967/68 was 26.5¢ per pound. Only Nicaragua is highly dependent upon cotton exports.
Brazil, North. . . . .	0.0	Most cotton here is a perennial type (and therefore unresponsive to annual price changes); where this cotton is grown there is very little in the way of alternative crops. Perennial cotton has the advantage of being able to survive drought.

--Continued

Table 24.--Estimated long-run responses of cotton acreage in foreign producing countries and regions to changes in world price levels, projection period of 1970-80--Continued

Country or region	Estimated price elasticity	Comments <sup>1/</sup>
<u>Less Developed--continued</u>		
Brazil, South. . . . .	0.8	: Based in part upon FAS unpublished analysis. This is a very low cost area, 12.0¢ per pound average direct and 16.3¢ total, while farm price in 1968/69 averaged 17.5¢ per pound. However, farmers have good alternative crop potentials, making this area more price responsive than might otherwise be the case.
Colombia . . . . .	1.0	: Farmers are considered to be price responsive. Costs are relatively high (total costs of 23¢ per pound average against an average price of 24¢ in 1968/69). There are good alternative crops but their profitability does not approach cotton's.
Peru . . . . .	0.8	: Cotton is produced on irrigated land, expansion potential is limited, and production costs are relatively high (26¢ per pound), although Peru's long and extra-long staple varieties command high prices. In some areas alternative crops are limited, but recent trends in the Tanguis area (2/3 of crop) indicate relatively high price responsiveness by producers.
Other South America. .	0.4	: Mostly Argentina and minor producers. Most production is for domestic use, as a means of saving foreign exchange.
East & West Africa . .	0.1	: Cotton production relatively isolated from international prices. In many places there are no alternative cash crops. In most countries, input costs (especially labor) are very low.
United Arab Republic .	0.1	: The UAR is the world's major supplier of extra-long staple cotton (ELS). The Government sets the acreage and farm price, isolating the grower from prices on world markets. Egypt is an efficient producer and the domestic market takes about a third of the crop.
Sudan. . . . .	0.1	: The Sudan is the world's other major supplier of ELS. Growers are isolated by government intervention from prices on world markets. There are few other alternative export crops.
Other North Africa . .	0.4	: Mostly Morocco. Growers here are not subject to as many government controls as in the UAR and the Sudan.
Iran . . . . .	0.2	: Should be relatively inelastic. The Ministry of Agriculture controls acreage and regions of cotton cultivation. Domestic consumption (about one-third) is important. Low cost producer. Average price in 1968/69 was 24¢ per pound, direct cost of production only about 17.1¢, and total cost was 21.2¢ per pound.

--Continued

Table 24.--Estimated long-run responses of cotton acreage in foreign producing countries and regions to changes in world price levels, projection period of 1970-80--Continued

Country or region	Estimated price elasticity	Comments <sup>1/</sup>
<u>Less Developed--continued</u>		
Syria . . . . .	0.6	Based in part upon FAS unpublished analysis. About 85 percent of total production is for the export market.
Turkey . . . . .	0.8	There are good alternative crops and markets. Domestic demand (one-third) is relatively important and a moderating factor.
Other West Asia. . . .	0.4	Cotton does not play a major role in the economies of these countries.
India. . . . .	0.0	Production goes mostly into domestic mill consumption. World prices should have little or no influence.
Pakistan . . . . .	0.3	Low response because of low cost production. The 1968/69 price averaged 22¢ per pound and direct costs of production were only about 15.7¢, and total cost was 20.1¢ per pound.
Other South Asia . . .	0.2	Mainly Afghanistan. Low response because of high domestic consumption needs and because much of the trade is for barter (with USSR).
South East Asia. . . .	0.4	High cost producers. Cotton production supplements imports. World price plays little or no role in Burma.
East Asia & Pacific. .	0.2	Production of minor importance.
<u>Weighted average <sup>2/</sup></u>	0.27 for acreage; 0.47 for production	
<u>Total Foreign Free World <sup>2/</sup></u>	0.27 for acreage; 0.46 for production	
<u>Total Foreign World . .</u>	0.20 for acreage; 0.28 for production	

<sup>1/</sup> A large domestic market and/or a low cost position generally contributes to a relatively inelastic acreage. High cost and a greater dependence on the export market contribute to greater elasticity. However, if cotton exports are an important part of foreign exchange earnings, a country could be an inelastic supplier even though it is a high cost producer. This is especially so where few alternative export crops (or markets) exist. <sup>2/</sup> The aggregate elasticity of acreage was obtained by weighting the individual elasticities by the respective 1965-67 average area. The aggregate elasticity of production resulted from weighting by 1965-67 average production. On an aggregate basis, the latter is higher (and more useful) than the former because of the usually higher yields which exist in the countries or regions with the greatest acreage responses to price (see discussion in text).

Source: Largely judgment based on review of historical trends, analysis of others (see table 20), USDA/FAS trip reports and attache reports, and the sector analyses presented in table 23.

1/ In the equations Y = area, yield, or production; T = time, and P = average price of SM 1-1/16 inch cotton, Liverpool, 1968 constant prices. 2/ Where Y in the equation represents production. 3/ No projections made where either the time or price coefficient was not statistically significant, see table 23. 4/ Held constant because price coefficient was not significant.

assumes a dropping off in rate of increase. <sup>32/</sup> Also, the inclusion of cotton price in the equations, with price set at 24 cents and above, always resulted in higher projections of area than the simple time trend projections. The latter assume a continuation of the declining prices of the historical period which, by 1980, would be less than 24 cents.

In brief, the projections provide the following guidelines for 1980:

- (1) Foreign developed: average yields for sector could exceed 700 pounds per acre, perhaps even 800 at a 30-cent cotton price (these seemingly too high yields will be explained later). Area not significantly affected by changes in world cotton prices.
- (2) Central plan: average yields for the sector could reach 475 to over 520 pounds per acre. Yields and area not significantly affected by changes in world cotton prices.
- (3) Less developed: area affected appreciably and average yields slightly by price changes. Under constant prices, total area could reach 55.9 to 56.7 million acres, average yields for sector could reach 307 to 316 pounds per acre, and production (area x yields) 35.8 to 37.2 million bales.
- (4) Total foreign world: area affected by changes in world cotton prices because of response in less developed sector. Yields not affected. Under constant prices, area could reach 73.9 to 74.7 million acres, yields 345 to 359 pounds per acre, and production 53.1 to 55.2 million bales.

The accepted projections of regional area, yields, and production are shown in table 26. The choices were made after examining linear trends, projections made by others, the guidelines provided by the direct sector projections, and by judgments based on an analysis of the factors discussed under "Factors Affecting Production Trends." The linear trends were mostly run on 10- or 11-year periods ending with the 1968/69 crop year.

Initial projections were made under the assumption of a 30-cent price. Projections at 28-, 26-, and 24-cent prices were made by adjusting downward the initial area projections in accordance with the price elasticities estimated for each region. Regional yields in 1980 were assumed to be not affected by price changes, which is a simplifying abstraction. However, in each sector except the central plan, sector yields did decrease with decreases in price because of the higher area responses in regions with the highest yields.

The regional projections add up to a foreign world production in 1980 ranging from 54.4 million bales (11.8 million metric tons) at a 24-cent price up to 57.4 million bales (12.5 million metric tons) at a 30-cent price. These foreign world production projections as well as the area and average yield projections on which they are based fall close to the linear direct projections presented earlier.

To balance world cotton production with cotton use, U.S. production in 1980 would need to range from 9.4 million bales at the 30-cent world price to 14.3 million bales

---

<sup>32/</sup> Note that in the semilog equations, time, not the dependent variable, is expressed in logarithms (i.e.,  $Y = a + b \log T$ ). This equation was used because projections with a decreasing rate of growth over time were desired.

1/ Assumes medium economic growth and various price levels. Price refers to SM 1-1/16 inch cotton, c.i.f., Liverpool, 1968 constant currency. 2/ Figures may not add or convert exactly because of rounding. 3/ What U.S. area and production would need to be if world production were to equal world cotton use at the given price. 4/ Excluding United States.

at 24 cents. <sup>33/</sup> This would require only between 7.2 and 10.9 million acres, compared with an average of 11.4 million in 1965-67.

At a 26-cent world cotton price in 1980, world cotton productions would equal world cotton use of 14.8 million metric tons, with a U.S. production level of 2.74 million metric tons (12.6 million bales). This level of world production would be around one-third larger than the average output of 1965-67 (table 27). Nearly two-thirds of this increase in world production is projected to occur in the less developed sector, increasing this sector's share of world production from about 45 percent in 1965-67 to 50 percent in 1980. Shares of both the developed and central plan sectors would decrease by 2 to 3 percentage points.

Regions with the largest projected increases in production at the 26-cent price level are India, Mainland China, the USSR, East and West Africa, the United States <sup>34/</sup>, Brazil, and Pakistan. Mexican and Central American production at this price level in 1980 is likely to be below 1965-67 averages. At a 26-cent price, the United States would remain the world's largest producer, but at a higher price (which is likely only if the United States cuts back production) it would probably be surpassed by the now second place USSR.

Large acreage expansion is projected for East and West Africa, Brazil, the USSR, Pakistan, and the Sudan. In most other regions, the production increases will come heavily from yield improvements.

The projections accepted here at a 26-cent price are higher than those made in 1967 under a similar price assumption for the National Advisory Commission on Food and Fiber (NACFF). <sup>35/</sup> The principal differences are higher projections for South Asian and African countries, which now seem more probable than then.

The Indicative World Plan (IWP) projections show for 12 less developed regions a total production in 1980 of 30.9 million bales, a slightly higher figure than the 29.2 million bales projected for the same regions at a high 30-cent price. The IWP appears extremely optimistic for South Asia, with 4 million bales over what seems reasonable. However, Brazilian production may well be a million bales above the IWP goal.

Supply and Demand study (S&D) projections available for some countries tend to be optimistic. <sup>36/</sup> Compared with the S&D projections, substantially lower production is anticipated in 1975 and 1980 in Mexico, Central America, Peru, Brazil, and India. However, expected 1980 production in Pakistan would be nearly 1 million bales above the S&D projection.

Alternative high and low projections of LDC production in 1980, which correspond to the high and low LDC income projections of cotton use, are presented in table 28.

---

<sup>33/</sup> This residual production assumption does not imply a passive role, since U.S. pricing and export policy could influence world price and thus the size of the residual in the long run.

<sup>34/</sup> This would be an increase over the low 1965-67 production level but a decrease over levels of the late 1950's and early 1960's.

<sup>35/</sup> Projections by NACFF and others are presented in appendix tables C-3 and C-4.

<sup>36/</sup> These studies, which were made in the respective countries under contract with the USDA, are footnoted in the Literature Cited.

<sup>1/</sup> Price refers to SM 1-1/16 inch cotton, c.i.f., Liverpool, constant 1968 currency.<sup>2/</sup> Figures may not add or convert exactly because of rounding. <sup>3/</sup> What U.S. production would need to be if world production and cotton use were to be in balance at the given price. <sup>4/</sup> Excluding United States.

The low projections assume a substantial decline in rate of production growth. 37/ Both assume a world cotton price of 26 cents in 1980.

Under the high growth assumption, LDC and foreign world production would be some 0.9 million metric tons (4.2 million bales) above the accepted (medium) projections, and U.S. production would need to increase by 300,000 metric tons (1.5 million bales) to balance world production and consumption. The required increase in U.S. production on top of the increase in LDC production seems an inconsistency, but results from the increase in LDC cotton use under the high assumption exceeding the growth in LDC production under the same assumption. This would leave a larger "residual" for the United States to fill, as we shall see better when we project cotton lint exports.

Under the low LDC growth assumption, the projected increase in LDC production, although still sizable, would be less than the projected expansion of cotton use under the same assumption. This would again leave an additional residual, but a smaller one than the high growth case, for the United States to fill. 38/

---

37/ The high projections were made by increasing the compared growth rate in production between 1965-67 and 1980 (26-cent price assumption) by 1.4 times. The low projections were made by dividing the same growth rate by 1.4.

38/ LDC cotton use increases more than production in both the high and low cases, but not in the medium or most likely case, because of the income projections. Under the high assumption, per capita income and thus projected cotton use are substantially above the medium projections. However, under the low assumption, per capita income and thus projected cotton use are lower than the medium projections, but not to nearly the same extent as the high projections are above.

## OUTLOOK FOR COTTON TRADE

About one-fourth of total cotton trade volume in recent years has moved as textiles, and three-fourths as cotton lint. The outlook for each is considered in this section.

### Outlook for Cotton Textile Trade 39/

#### Situation and Trends

Developed regions of the world handled over half of the total world trade in cotton textiles in 1965-67 (table 29). Central plan areas exported about 17 percent and imported about 5 percent of the total quantity. Less developed regions accounted for about a third of world exports and 38 percent of the imports.

Major trading regions.--The EC countries together export and import more cotton textiles than any other region. However, Hong Kong and Japan are the largest export countries, followed by India and Mainland China. Other major exporters are the United States, the individual EC countries, Egypt, Portugal, the United Kingdom, the USSR, the countries of Eastern Europe, Taiwan, Spain, and South Korea.

On the import side, the United States ranks second behind the EC, followed by the United Kingdom, East and West Africa, Other Western Europe, Other East Asia and Pacific, Hong Kong (mostly for clothing manufacture and reexport), Australia-New Zealand, and Canada.

Net trade.--Cotton textile imports exceed exports in all the DR's except the EC and Japan (table 30). The CPR's were all net exporters in 1965-67. The LDR's are divided about equally into net exporters and net importers.

Japan, with little imports to offset its exports, is the world's major net exporter of cotton textiles. Next to Japan in net exports are Hong Kong, Mainland China, and India.

Changes in quantity of trade.--Significant changes in cotton textile trade have occurred since the early 1950's. Imports of the DR's have grown much more than exports, while just the opposite has occurred among the CPR's and LDR's as groups (table 30). For the DR's, the relative change was over 300 percent for imports, but only about 30 percent for exports. During the same period, total textile exports of the CPR's increased almost fourfold and those of the LDR's more than doubled. Imports of the LDR's in total increased only slightly.

---

39/ Data on cotton textile trade are less comparable and up-to-date than those on cotton lint. Problems include: the separation of cotton items from trade in other textiles, the estimation of the cotton content or value of blended items, and the conversion of quantities of different items to a common denominator, such as metric tons. FAO quantity data have most of these problems; in particular, they omit the trade of many clothing items and at the time of analysis were fairly complete only up to 1964. FAO has improved and updated the series; (this became available in the spring of 1970, but too late for inclusion in the analysis of this study). Revised data for 1960-66 are available for a few selected countries. GATT gathers and publishes both quantity and value data for countries participating in the Long-Term (Cotton Textile) Agreement. However, again the quantity data are frequently incomplete. The value data are more inclusive of all cotton textile trade, but since they reflect price and mix changes, also are not good indicators of changes in physical trade. The textile trade data used in this study were on an actual weight basis, rather than lint cotton equivalent. For more discussion, see appendix A.

1/ A minus indicates net exports. 2/ Percentage increase over 1,000. 3/ 1953-64.  
4/ 1964. 5/ Includes Peru.

Source: Calculated from table 29.

Between 1953 and 1965-67, regions with the largest absolute increases in export quantity were Hong Kong, Eastern Europe, Other Western Europe, EC, Mainland China, Japan, and Pakistan. Largest increases in import quantity occurred in the EC, the United States, the United Kingdom, Other Western Europe, and Hong Kong (mostly for processing and reexport).

The significance of the changes is most evident in net trade. Since 1953, both the United States and the United Kingdom changed from net exporters to substantial net importers of cotton textiles. Net exports of the EC have dropped by three-fourths. In contrast, Hong Kong's net export position more than tripled, and those of the UAR, South Korea, Taiwan, and Pakistan increased by even larger proportions. Japan's net exports expanded by one-half, but declined greatly in 1967.

Many LDC's of minor importance in world textile trade have expanded exports or reduced imports through expansion of domestic textile industries. Brazil, Colombia, Turkey, Pakistan, South Korea, and Taiwan have all moved from net imports in 1953 to net exports now. Iran, Other North Africa, Other South America, Southeast Asia, and Other East Asia and Pacific have all reduced net imports.

#### Factors Affecting Cotton Textile Trade

The extent to which a country or region imports and exports cotton textiles depends upon: (1) comparative cost of textile manufacture, (2) product pricing policies, (3) import restrictions on cotton textiles, and (4) trade and economic development policies.

Textile manufacturing costs.--Classification of regions and countries, according to their level of development and cotton textile trade patterns, can be made as follows: (1) importing DC's, (2) low price exporters, (3) self-sufficient LDC's, and (4) net importing LDC's.

The first group, which includes all of the DC's except Portugal and Japan, provides the principal markets for the low cost exporters. Although many--the United States, the United Kingdom, and EC members--still have substantial exports, most trade remains within the group. <sup>40/</sup> The Canadian and Australian cotton textile industries have always supplied less than their domestic needs.

The second group, low price exporters, includes Japan, Portugal, Hong Kong, South Korea, Taiwan, India, Pakistan, the UAR, several Eastern European countries, and Mainland China. These countries accounted for most of the increase in world textile exports during the past decade. <sup>41/</sup>

The third group, self-sufficient LDC's, encompasses many countries which supply most of their domestic textile needs but, as yet, do not export large quantities. Included are the larger Latin American countries (e.g., Argentina, Brazil, Colombia, and Mexico), and some West Asian countries (e.g., Turkey, Syria, and Iran). Some of these countries are potential low price exporters, but the majority support relatively inefficient industries behind tariff protection.

The last group, net importing LDC's, include the smaller Latin American Republics, most African, and many Asian countries. Many of these countries are developing cotton

---

<sup>40/</sup> Many individual Western European countries, notably Belgium, France, Italy, Greece, Spain, and Switzerland remain net exporters.

<sup>41/</sup> Not all these countries are low cost producers, see discussion under "Product Pricing Policy." Japan's costs of production are rising rapidly and may move the country out of the low price exporter category.

textile industries to supply their domestic markets. Not many of the countries in this group are likely to emerge as important low price textile exporters before 1980.

Regional differences in the costs of cotton textile production were major determinants in shifts of mill consumption and cotton textile trade over the past decade and a half. By 1967, the low price exporters were supplying substantial proportions of the cotton textiles consumed in the DC's: 7.5 percent in the United States; 5.2 percent in the EC; and 30.2 percent in the United Kingdom. <sup>42/</sup>

Several Asian exporters and Portugal enjoy a total cost advantage over the United States and Western European textile producers of 10 to 25 percent in cotton yarn spinning and of 10 to 30 percent in weaving gray cotton fabrics (69, pp. 31 and 121). Tariffs in the DC's do not compensate for cost differences of this magnitude. These average cost advantages (for upper quartile mills) are achieved because of lower labor costs (table 31), and--to a lesser extent--lower raw cotton costs in the low cost countries (69, pp. 33 and 37), even though labor productivity is much higher in Western Europe and (especially) the United States.

Where labor is expensive and the textile industry more capital intensive, as in the DC's, it is necessary to use better quality cotton to minimize breakages. The low labor cost countries are therefore able to save additionally on input costs by using lower quality cotton. Average cost per pound for cotton used in spinning 20-count yarn ranged from 27.9 to 33.4 cents in November 1967 for the nine countries listed in table 31 (69, p. 37). The cotton costs correlated closely with the wage costs. <sup>43/</sup>

Low price exporters which grow cotton, such as Pakistan, may have an additional slight advantage in the purchase price of raw cotton. However, only about 30 percent of textiles exported over the past decade originated in cotton-producing countries (table 29). This percentage has remained quite stable.

During the next decade it is possible that the DC's may be able to improve their competitive positions vis-a-vis the low price exporters. Low cost areas may have less incentive for installing more modern looms and new capital intensive machinery, thereby giving the DC's a faster rate of growth in labor productivity. According to GATT figures, labor and machine productivity is already increasing at a faster rate in the DC's (35, p. 29). Nevertheless, it is unlikely that the DC's will be able to completely overcome the low cost textile producers' price advantage by 1980.

Product-pricing policy.--Many importing countries claim that some of the low price exporters are able to compete not because of low production costs but because of below cost selling. This complaint applies principally to the UAR and central plan exporters whose prices may frequently bear no relation to costs, but also applies to many LDC's whose need for foreign exchange makes them willing to subsidize textile exports. Among the latter, countries frequently mentioned are Pakistan, India, Mexico, and South Korea (69, p. 22, and U.S. Embassy Report, Seoul, November 1969).

Import restrictions on cotton textiles.--Restrictions on cotton textile imports are numerous. In addition to fairly high tariffs, there are other taxes, quotas, and restrictive arrangements. These restrictions for selected countries and regions are summarized in table 32.

<sup>42/</sup> The very high figure for the United Kingdom is partially due to the tariff-free status granted cotton textile imports from the Commonwealth and the EFTA (Portugal).

<sup>43/</sup> This argument is disputed by some, but cotton cost data is difficult to obtain. The argument, moreover, does not apply to countries which manufacture high quality domestic cotton as, for example, the UAR.

Table 32.--Import restrictions on cotton textiles, selected countries and regions, 1969

Country or region	Tariffs	Kennedy Round Concessions	Nontariff barriers
<b>Developed</b>			
United States <sup>1/</sup>	9 to 23% on most important items. Highest rates on clothing. Preferential rates to the Philippines until 1974.	On most items. Range to be lowered to 7-1/2 to 21%.	Bilateral agreement levels generally allow for annual average increases of around 5% in accordance with spirit of the LTA.
Canada <sup>1/</sup>	10 to 22%. Highest on clothing, lowest on yarns. Commonwealth preference to the U.K., India, Pakistan, and Singapore, but not to Hong Kong. Preferential rates are from free to 1/2 the MFN rates.	On most items. Full 1972 cuts already made.	Various taxes plus quantitative restrictions and arrangements. Under an exception to terms of the LTA, Canada does not agree to annual import increases of a full 5%.
EC <sup>1/</sup>	Common external tariff of 6.4 to 18% for most items. Highest on clothing. No tariffs on intra-EC trade.	On most items. Range to be lowered to 4 to 17%. Has reserved right to repeal its Kennedy Round tariff cuts if LTA is not renewed when it expires in 1970.	Various taxes. All except France require import licenses. Quantitative restrictions and bilateral arrangements. France has a quota system.
EFTA	No common external tariff. Most duties in 10 to 20% range, highest on clothing. No tariffs on intra-EFTA trade, except Portugal which gives preferential rates.	On most items by most members.	Various taxes in all countries. Switzerland and Portugal license imports.
United Kingdom <sup>1/</sup>	7-1/2 to 28% on most important items. Lowest on yarns, highest on clothing. No tariffs on imports from EFTA or Commonwealth countries. However, duty-free status of latter will be eliminated by 1972.	On most items. Range to be reduced to 7-1/2 to 20%.	Tax to compensate for taxes on domestic products. Quantitative restrictions and arrangements. Under terms of the LTA, the U.K. accepts only a 1% annual increase in imports.
Japan <sup>1/</sup>	4.4 to 22%. Highest rates on fabrics and clothing. No preferential rates.	On all items.	Various taxes and many other restrictions intended to keep imports very low.
Australia <sup>1/</sup>	30 to 60%. Highest rates on clothing. Commonwealth preference given to U.K., Canada, and Ireland. Other Commonwealth members negotiate for preferences. A special LDC preference is given on a limited number of yarn and fabric items within quotas.	None.	Various taxes.
South Africa	1% average on yarns. Fabric, \$0.14 to 0.17/sq. yard. Clothing, 20 to 25% average. Preferential rate on fabric imports from the U.K.	None.	Quotas on most items. Import licenses required. Minor taxes. Complex invoice system.
Central Plan			
Eastern Europe	None.	Not a party.	Import licenses plus quotas. All imports controlled by a central buying agency.
<b>Less Developed</b>			
LAPTA	No common external tariff. Rates of member countries are generally high, 85-over 100%. Very few concessions yet on intratrade although more are likely among Andean Group countries.	None.	Import licenses required but usually difficult or impossible to obtain.

<sup>1/</sup> Members of the Long-Term Agreement on Cotton Textiles.

Sources: Tariff books of the cited countries; also 29, 61, 69.

The tariffs of the developed countries on cotton textile imports range between 5 and 25 percent ad valorem for most countries, with the prominent exception being Australia where duties range from 30 to 60 percent. The tariff rates generally increase with the degree of processing (i.e., the rates are lowest on yarns and highest on clothing). The tariffs imposed by the LDC's are generally in the range of 100 percent or more, if imports are allowed at all.

Kennedy Round tariff cuts on cotton textile products granted by most of the developed countries were generally in the range of 20 to 25 percent. These are programmed to take place in stages and will be complete in 1972.

Special tariff preferences on cotton textiles are given within the various trading blocs. In the EC there are no tariffs on trade among the six members and a common external tariff applies to third countries. However, tariff concessions are given to associate members - Greece, Turkey, the 18 African associates <sup>44/</sup>, political dependencies of France and the Netherlands, and to partial associates - Morocco, Tunisia, and the East African Community (Kenya, Tanzania, and Uganda). <sup>45/</sup>

The eight member states of EFTA have eliminated tariffs on intra-EFTA trade in industrial goods, except for Portugal and Iceland which are in the process of eliminating tariffs. Also, special trade concessions are given Finland, an associate member.

Great Britain levies no tariff duties on textile imports from Commonwealth members <sup>46/</sup>, and other members grant special tariff rates to all or some of the Commonwealth countries. Many members also grant Commonwealth preferential rates to Ireland and the Republic of South Africa, although these countries are no longer members.

The Central American Common Market (CACM) has a common external tariff, but levies no tariff on intratrade. The Latin American Free Trade Association (LAFTA) has no common external tariff and grants few concessions on intraregional trade.

Nontariff measures are often much more restrictive than tariffs and are applied by both developed and less developed countries. These restrictions take the form of taxes to compensate for similar taxes on domestic products, other special taxes, import licensing, quotas, and "voluntary" arrangements which restrict the quantity of imports. Some LDC's (e.g., Pakistan, Brazil, and the UAR) prohibit the importation of cotton textiles.

The Long-Term Agreement on Cotton Textiles (LTA) is a multilateral agreement under GATT intended to regulate the growth of cotton textile exports from low price exporters to the United States, Canada, Australia, and Western Europe. The LTA became effective for 5 years on October 1, 1962, and has since been extended for 3 additional years. The present agreement expires September 30, 1970. As of 1969, 30 countries were members of the LTA:

---

<sup>44/</sup> Burundi, Cameroon, Central African Republic, Chad, Congo (Brazzaville), Congo (Kinshasa), Dahomey, Gabon, Ivory Coast, Madagascar, Mali, Mauritania, Niger, Rwanda, Senegal, Somali Republic, Upper Volta, Togo.

<sup>45/</sup> The agreement with the East African Community is dependent upon the completion of the ratification procedure.

<sup>46/</sup> Beginning in 1972, tariffs will be applied to Commonwealth countries.

Australia	Mexico
Austria	Pakistan
Canada	Poland
Colombia	Portugal (including Macao)
Denmark	Taiwan
EC (all 6 members)	South Korea
Finland	Spain
Greece	Sweden
India	Turkey
Israel	UAR
Jamaica	United Kingdom (including Hong Kong)
Japan	United States

The stated purpose of the agreement is to provide for the "reasonable" expansion of cotton textile exports from the LDC's and Japan without "disruptive" effects on the markets of the importing countries. Importing countries may limit the imports of particular products from LTA members if these imports cause or threaten to cause "market disruption."

Before the inception of the LTA (and its predecessor, the Short-Term Agreement), the DC's were accepting very unequal shares of the growth in LDC cotton textile exports. The LTA opened many Western European markets that had previously placed excessive restrictions on cotton textile imports from the LDC's. Two mechanisms protect DC importers from onslaughts of imports which they consider to be disruptive of their markets. The first is a specialized agreement between an importing country and an exporting country which limits the exports of a particular item.

The second is a general bilateral agreement. These are usually of 1 to 5 years duration and cover trade in all textile products. Most major DC importers have bilateral agreements with most of their suppliers of low price cotton textile imports. The United Kingdom, the United States, Japan, Canada, and the Western European countries, roughly in that order, have negotiated the greatest number of bilateral agreements on cotton textile trade.

Bilateral agreements are reached with nonmembers as well as members of the LTA. Under these agreements the United States and most other DC importers have agreed to allow an annual 5-percent increase in imports from each of the low price exporters. However, the United Kingdom, whose market has been penetrated very deeply by low priced imports, has agreed to only a 1-percent annual increase in most of its agreements. Canada's agreements also stipulate a less than 5-percent annual increase in imports.

One of the effects of the LTA has been to boost LDC exports at the expense of Japanese exports. In the United States, the LTA had the effect of putting a ceiling on Japanese imports and thus making it easier for other low price exporters to compete in the U.S. market.

The LTA has had an unexpected effect to the disadvantage of cotton producers. The LTA limitations on the growth of cotton textile imports have caused some textile exporting countries to expand the use of manmade fibers in the production of textiles for export. Most low price exporters have increased their exports of manmade fiber textile exports much more rapidly than cotton textile exports.

The long-term outlook is for continued import restrictions on cotton textiles. The operation of the LTA has demonstrated, however, that the DC's are willing to allow gradual and "orderly" increases in imports.

Trade and economic development policy.--Many net importing LDC's, because of the desire to industrialize their economies and save on foreign exchange, have set up cotton textile mills behind protective tariff barriers. These new import substitution industries, as well as the competition from low price exporters in the net importing LDC's, have cut into former markets (and production) of DC cotton textile industries. The principal future impact of this import substitution policy should be the placing of additional pressure on the DC markets to accept imports from the low price exporters (who will be losing LDC markets).

#### Reliance on Textile Imports

Trends.--Between 1953 and 1965-67, imports supplied a declining proportion of the domestic cotton textile needs of most LDC's, but an increasing proportion of cotton textile use in the CPC's and DC's, except in South Africa (table 33). Reliance on cotton textile imports decreased by one-half or more in Iran, South Africa, Other South America, the Sudan, and South East Asia; and by one-third in East and West Africa, Other North Africa, Syria, and Other East Asia and Pacific. In contrast, the percentage of the market supplied by imports increased substantially in the United Kingdom and the EC.

Prospects.--The expected reliance of various regions on cotton textile imports was projected by trend extension and adjustments to reflect changes in the affecting factors. The results show reliance increasing the most in Canada, the EC, and the United States (table 33). The biggest declines are projected for Central America, Other West Asia, and Other East Asia and Pacific.

It was impossible to determine or project import reliance in Hong Kong because of the large volume of reexports. In all probability, very little of the import volume moves into domestic use.

#### Import Projections

Projections of cotton textile imports in 1980 were made by applying the projected import reliance to total domestic cotton use. In the case of Hong Kong, direct projections of imports were made from time series data. The results are shown in table 34.

The projections show world cotton textile imports in 1980 at around 2.2 million metric tons, up from 1.6 million in 1965-67. Over two-thirds of the increase will be taken by DC's, and about one-quarter by the central plan countries. Little expansion is shown in LDC imports because of expanding domestic mill capacity.

Individual regions with high projected increases in cotton textile imports are the United States, the EC, the USSR, and Other Western Europe. These four regions alone may take more than 80 percent of the increase in world cotton textile trade.

Changes in the world price of cotton lint are likely to have a minimal affect on 1980 trade in cotton textiles because of the numerous trade restrictions and other factors involved. Thus, only single projections were made for each region.

High LDC economic growth could boost imports by this sector by 0.1 million metric ton over the medium projections, raising world imports to 2.3 million metric tons. Alternatively, low LDC economic growth could reduce the growth in LDC sector imports and hold world imports to possibly around 2.1 million metric tons in 1980.

Most of the changes in LDC imports under the high and low assumptions, compared with the medium projections, would be by countries of Africa, Other East Asia and

Source: 1965-67 imports are FAO (25).

Pacific, and South East Asia, all of which have low levels of industrialization. It may be that with high economic growth, domestic mill use in these countries would expand sufficiently to fill domestic needs without additional textile imports. The projections as accepted, however, assumed that the proportion of domestic needs filled by imports would hold constant under the three alternatives.

#### Export Share Trends and Prospects

Trends.--Between 1953 and 1965-67 the CPC's and LDC's expanded their shares of world cotton textile exports mostly at the expense of the DC's (table 35). The biggest gains in export share were made by Hong Kong, Communist Asia, Pakistan, Other Western Europe, Eastern Europe, the UAR, and Taiwan. Those who gave up the biggest trade shares were the United Kingdom, the United States, the EC, and India.

Projected shares in 1980.--Regional shares of world cotton textile exports in 1980 were projected by extending linear time trends and making adjustments based on the factors discussed earlier. The DC's can be expected to continue losing export markets to the CPC's and LDC's. By 1980, the LDC's may be exporting nearly half the world total up from one-third in 1967. In exact contrast, the DC's share may drop from almost one-half of world cotton textile exports in 1965-67 to one-third by 1980. The CPC's are likely to maintain something near their present share.

The market losses will be shared by most developed regions except Other Western Europe, whose low price exporters (principally Portugal, but including Spain and Greece as well) are likely to continue expanding their market shares. Taiwan, South Korea, Pakistan, and the UAR are all expected to substantially increase their market shares. Slow growth or declines in the market shares of Japan and Hong Kong are attributed in part to rising costs of production and to increased emphasis on manmade fibers by their textile industries.

#### Export Projections

Total world exports of cotton textiles in 1980 are projected to equal total world imports--2.13 to 2.29 million metric tons, depending upon the economic growth assumptions. Projections of regional textile exports were made by multiplying projected total world figure by each region's prospective share. The results are shown in table 36.

Nearly two-thirds of the increase in world cotton textile exports will come from the less developed sector. The largest increases in exports are projected for the traditional low price exporters: Hong Kong, South Korea, Pakistan, and the UAR. However, some expansion is also projected in exports of Other Western Europe (Portugal, Spain, and Greece, in that order) and Eastern Europe.

Japan's exports of cotton textiles probably will not increase because of the rapid switch to manmade fibers, but Japan will maintain its place behind Hong Kong as the second largest cotton textile exporting country (a position it fell to in 1967). Several less developed countries and regions will have large percentage increases in exports because of small base period exports. Some of these - Mexico, Brazil, Turkey, to name a few - could come on much stronger than projected if domestic industry problems are resolved.

High LDC economic growth could boost sector exports by 0.05 million metric tons over the medium projections, with most of the increase coming from Hong Kong, Pakistan, India, and Taiwan. Exports of the developed and central plan sectors might also be higher if they maintained projected export shares. Alternatively, low LDC economic growth could reduce LDC sector exports by 0.02 million metric tons over the medium projections, and world exports by 0.5 million tons. World exports would be lower because of fewer imports by LDC's from developed and central plan exporters.

Source: 1965-67 exports are FAO (25); projections are based on world import projections and projected shares of world exports.

### Net Trade Projections

Projected exports of cotton textiles were subtracted from projected imports to obtain net trade in 1980. The results indicate a substantial increase in net imports by the developed sector, supplied mostly by expanded net exports of the LDC's (table 37).

Of the developed regions, only Japan will remain a net exporter, but with a deteriorated position, compared with the middle 1960's. The EC, which is the only other net exporting region now, is projected to follow the historical precedent of the United States, United Kingdom, and others, and become a net importer by 1980. However, some individual EC and Other Western European countries will remain net exporters, as was brought out in previous discussion.

In the central plan sector, Eastern Europe is projected to substantially increase net exports by 1980. In contrast, the USSR will become a net importer.

Among the LDC's, most of the net exporters of the recent past are projected to expand net exports by 1980. Most of the present net importers are projected to continue with about the same net position, because of expansion in domestic industries at about the same rate as cotton use increases. There could be some surprises here; for example, the Sudan, some other African countries, and Brazil could conceivably become net exporters or larger net exporters.

Under the high and low LDC economic growth assumptions, some interesting changes in net trade are projected. Under the high assumption, the LDC exports are projected lower than the medium projections, because of increased domestic demand for textiles in which the additional imports exceed expanded exports. The developed sector would have lower net imports because of apparent additional exports to the LDC's. The central plan sector would have a slight improvement in net exports, also because of more shipments to LDC's.

Under the high assumption, the projections indicate that Africa, Other East Asia and Pacific, and South East Asia would need to increase net cotton textile imports to satisfy demand. However, demand might be satisfied from a faster rate of expansion in domestic mill capacity than that assumed, in which case the cotton would come from increased lint imports or decreased lint exports.

### Outlook for Cotton Lint Trade

#### Situation and Trends

The less developed sector exports are over 60 percent of world trade in cotton lint, but imports are only about 17 percent (table 38). It is thus a heavy net exporter. In contrast, the developed sector, mainly the United States, exports one-fourth of world trade, but imports nearly 60 percent and provides the major market for LDC exports. The central plan sector exports considerable cotton, but imports even more to provide a market for LDC cotton.

The world's largest cotton exporters in 1965-67 were the United States with about 23 percent of the total, and the USSR, with about one-seventh. Other major exporters are Mexico, the UAR, East and West Africa, Central America, Brazil, Pakistan, the Sudan, Syria, Peru, and Iran. Since 1967, Brazil has moved up to third place ahead of Mexico. In Central America, the largest exporters are Nicaragua and Guatemala. In East and West Africa, they are Uganda, Tanzania, Mozambique, and Chad.

Source: USDA/FAS.

Raw cotton exports of all major exporting regions have been increasing, except for the United States and Mexico. Between 1955-57 and 1965-67, the largest absolute increases took place in the USSR, Turkey, Central America, Brazil, and the Sudan. U.S. exports dropped by nearly one-fourth. Mexico maintained exports at about the same level.

Major importing regions are EC, about one-third of the total; Japan, over one-fifth; and Eastern Europe, over one-sixth. Other major importers are the U.K., Hong Kong, the USSR, India, Communist Asia, Canada, Taiwan, and South Korea.

World imports of raw cotton increased by about 0.7 million metric tons in the decade 1955-57 to 1965-67. About a third of this increase went to East Asia, mainly Hong Kong, South Korea, and Taiwan. Another third went to Eastern Europe. Japan took about one-fourth (for the largest increase of any one country). Some expanded importation also occurred in the USSR (mostly high quality cotton from the UAR), India (P.L. 480), and Mainland China. Imports by the EC and U.K. actually dropped off because of manmade fiber competition and increased cotton textile imports.

#### Direction of cotton lint trade

Destination of exports.--Table 39 shows the destination of exports from the major cotton-exporting regions. U.S. cotton lint exports go primarily to Japan, Western European countries, Canada, and the East Asian countries of Hong Kong, South Korea, and Taiwan. In the case of the USSR, about 80 percent of the exports go to Eastern Europe, 15 percent to Western Europe, and some to Japan and Canada (although the proportion to these latter two countries has recently increased substantially). Latin American exports have gone primarily to Japan and Western Europe.

Exports from the North African countries of the UAR and the Sudan move heavily into the central plan areas of Eastern Europe, the USSR, and Mainland China, and considerable exports are also made to Western Europe and, to a lesser extent, to Japan and other East Asian countries. West African exports, as might be expected, move heavily to Western Europe and, to a lesser extent, to Eastern Europe. Exports from East Africa, on the other hand, move heavily to Communist Asia and other East Asian countries. South Asian cotton, produced mostly in Pakistan, moves primarily to Japan, other East Asian countries, and the USSR.

Source of imports.--Table 40 shows the sources of imports into the various regions. U.S. imports are mostly extra-long staple cotton from Latin America (Peru) and North Africa (UAR and Sudan). Canada's imports are mostly from the United States, although less so recently because of increased imports from the USSR (as a reciprocal measure for USSR purchases of Canadian wheat). Japan receives about half its cotton from Latin America, a third from the United States, and most of the rest from Pakistan and North Africa. Western Europe's imports are divided among the United States, Latin America, and, to a lesser extent, West Asia and Africa. A small proportion comes from Greece.

Over half of Eastern Europe's imports are from the USSR, with most of the rest originating in North Africa and West Asia. Half the USSR's imports is extra-long staple cotton from North Africa, with other growths from West Asia, Pakistan, and Latin America making up the rest. Communist Asia's imports come mostly from North and East Africa, West Asia, and Pakistan.

In South Asia, India is the major importer, with about half coming from the United States, a third from North Africa, and a little from East Africa. Almost none comes from its close neighbor, Pakistan. Of East Asian imports, over half has been from the United States, with Latin America and Pakistan the other major suppliers.

### Factors affecting trade

The extent of a region's imports or exports of cotton lint depend mostly upon the surplus or deficit existing after balancing out domestic cotton use, textile trade, and cotton production. Thus the factors which affect each of these items also affect trade in cotton lint. Since these factors were discussed in previous sections, there is no need for more here. However, two other significant factors affect trade in cotton lint. These are special requirements or considerations and import restrictions.

Mill requirements for special types of cotton or other considerations frequently require some net exporters of cotton lint to import cotton and permit some net importers to export. Also, in multicountry regions, the region as a whole may be a net exporter but some individual countries remain importers, and vice versa.

One-half to two-thirds of U.S. imports are long staple and extra-long staple cotton. It appears that the Soviet imports (mainly from Egypt) and Pakistan imports also consist principally of longer staple cotton.

Net exporting regions in which some countries import cotton to meet domestic needs are Central America and Caribbean (imports are mostly by Caribbean countries), East and West Africa, Other West Asia (Israel imports high quality cotton) and Other South Asia (Afghanistan exports, others import).

India is a net importer of raw cotton, exporting some excess short staple and importing longer staple cotton. In several other net importing regions as set up for this study, there are one or more exporters. In Other Western Europe, it is Greece; in Other South America, Argentina and Paraguay export small amounts; in Other North Africa, Morocco exports some high quality cotton; in South East Asia, Burma is the only exporter.

Import restrictions on raw cotton are generally minor or nonexistent in noncotton-producing countries, or those which produce only a small fraction of the amount required for domestic mill consumption (table 41). However, cotton-producing countries generally place prohibitive restrictions upon raw cotton imports, usually allowing limited entry only of those types of cotton not produced domestically.

Import preferences for raw cotton are given by some countries. In Latin America, importing LAFTA countries give substantial preferences to cotton imports from fellow LAFTA members. The EC, under the first Yaounde Convention (1963-69), supported the price of cotton in many of the 18 Associated Overseas Countries (AOC) in Africa. Under the recently negotiated second Yaounde Convention (1970-75) price-support aid is eliminated, but the Community is sponsoring a new series of trade promotion measures for the AOC countries. In addition, associated countries whose economic situation is endangered by sudden declines in world prices of exported primary products will qualify for exceptional grants in aid.

In central plan countries, most trading is done by government institutions. Barter deals and special arrangements are prevalent. Eastern European countries have strong incentives to purchase cotton lint needs from USSR.

Import restrictions on raw cotton trade are not likely to change much in the decade ahead.

Table 41.--Restrictions on raw cotton imports, selected countries and regions, 1969

Country or region	Summary of restrictions
<u>Developed</u>	
United States . . . . .	Low tariffs, but restrictive import quotas - about 125,000 bales per year allowed, mostly extra-long staple.
Canada. . . . .	No restrictions.
EC. . . . .	No restrictions, except Germany and Netherlands have import quotas for cotton from the USSR or Mainland China.
United Kingdom. . . . .	No restrictions.
Greece. . . . .	Low tariff plus prior deposit.
Portugal. . . . .	No restrictions for imports from Portuguese overseas territories. Quota for other imports.
Spain . . . . .	Relatively high tariffs, but exporters of cotton textiles able to import equivalent amounts of raw cotton with substantial discounts in duties. Preferential quota to the UAR.
Other Western Europe. . . . .	No restrictions except Finland and Austria have preferential quotas for USSR cotton.
Japan . . . . .	No restrictions.
Australia . . . . .	Duty-free if all domestic crop is sold first.
South Africa. . . . .	No restrictions, but informal agreements require local spinners to buy at least 60,000 bales from domestic producers.
<u>Central Plan</u>	
Czechoslovakia & Hungary. . . . .	Ad valorem tariffs of 5% MFN, and 35% maximum.
Other Communist . . . . .	State trading.
<u>Less Developed</u>	
Latin America . . . . .	Most LAFTA members give substantial tariff concessions to other LAFTA members.
United Arab Republic. . . . .	Imports prohibited.
Syria . . . . .	A limited quota of ELS.
Turkey. . . . .	Limited quota of long-staple cotton.
India . . . . .	Low tariff. Strict import regulations. P.L.-480 imports important.
Pakistan. . . . .	Imports restricted to cottons not grown locally.
Hong Kong . . . . .	No restrictions (free port).
South Korea . . . . .	Low tariff. Free if textiles are exported. P.L.-480 imports important.
Taiwan. . . . .	Low tariff. Licensing regulations.

### Medium Trade Projections

Net cotton lint trade for each region in 1980 was taken as the balance existing after subtracting projected cotton production and textile trade from domestic use. Net trade was then converted to gross trade by projecting directly the imports of net exporting regions and the exports of net importers. <sup>47/</sup>

Under the assumption of medium economic growth, cotton lint trade in 1980 is projected to range from over 4.8 million metric tons at a 24-cent cotton price, down to about 4.6 million metric tons at a 30-cent price (table 42). Trade at a 26-cent price is projected at just over 4.7 million tons. This would represent a 0.9 million-ton increase over the 1965-67 average of 3.8 million tons, for an average annual increase of about 65,000 tons per year. The compound growth rate would be about 1.5 percent per year, compared with 2.0 percent per year during the period 1955-57 to 1965-67.

Imports by all three sectors are projected to be above 1965-67 levels (table 42). However, most of the expansion in imports will be taken by the LDC's, increasing their share of imports to around one-fourth, compared with 17 percent in 1965-67. The developed sector will take a decreasing proportion of world imports.

Imports are projected to increase with a lowering of world price, except in the central plan sector. Projected LDC imports are 90,000 tons higher at a 24-cent-price than at 30-cents, while those of the developed sector are 160,000 tons higher.

Regions with the largest projected increases in imports are Eastern Europe, Other East Asia and Pacific, South Korea, Japan, Taiwan, and Other Western Europe. Imports by the EC and U.K. are projected to hold at about 1965-67 levels.

Imports of the USSR will continue at substantial levels, for political and special requirement reasons. Communist Asia may import more cotton lint to fill domestic mill and end use needs. India's imports are not projected to change much, nor are those of Canada. Both South East Asia and Other South Asia will probably have increasing import needs.

Exports by the developed and less developed sectors in 1980 will depend heavily on world price. The projections show LDC exports as ranging from 2.9 million metric tons at a 24-cent world price up to 3.6 million tons at a 30-cent world price, compared with 2.3 million in 1965-66 (table 43). At the 24-cent price, the LDC share of world exports would be about 60 percent, nearly the same as 1965-67; but at the 30-cent price, it could approach 80 percent, a substantial increase.

To maintain the alternative prices in 1980 (unless unexpected changes occur in Soviet production and trade policy), U.S. exports would need to range from a low 0.2 million metric tons at the 30-cent price, up nearly to 1.2 million tons at a 24-cent price. The low export figure would represent a sizeable deterioration in U.S. position- while the higher export volume would maintain the U.S. share at about the 1965-67 level, 25 percent.

At a 26-cent world price the projections indicate U.S. exports of 0.84 million tons, central plan exports of 0.67 million, and LDC exports of 3.15 million tons. This would put U.S. exports at just under the 1965-67 level, but would be a sizeable expansion for the LDC's. Central plan sector (USSR) exports are not likely to be affected by changes in world prices.

The greatest increases in exports (with a 26-cent price level) are projected for East and West Africa, Brazil, Pakistan, the Sudan, and the USSR. Modest increases,

<sup>47/</sup> These latter projections were made by extending linear trends and adjusting in accordance with expected changes in affecting factors.

but in some cases large relative changes, are shown for Iran, Turkey, Syria, and Colombia. Lower exports than in 1965-67 are projected for Mexico, Central America and the UAR.

#### Alternative Projections

Alternative projections of cotton lint trade in 1980 were made under assumptions of a 26-cent cotton price and a higher or lower rate of LDC economic growth.

With high economic growth in the LDC's, world cotton lint trade in 1980 is projected at 5.1 million metric tons (table 41). This would be nearly 300,000 tons over the medium projections. Most of the increased importation would be by deficit cotton-producing LDC's; particularly India, Other South America, Other East Asia, Hong Kong, Taiwan, and South Korea. However, the developed regions would import slightly more cotton lint for textile manufacture and export to the LDC's.

Most of the increased lint imports by both LDC's and by DC textile exporters would come from the United States. This results from the higher increase in LDC cotton use than production under the high economic growth assumption. However, if the change in rate of cotton production exceeded the assumed change in the income growth rate, which is conceivable, LDC exports would expand and either price would fall from the 26-cent level or U.S. exports would be cut back.

With low economic growth in the LDC's, world trade is projected at 4.65 million tons, a drop of only 80,000 tons under the medium projection. Nearly all of the decreased importation would be by LDC's, principally Other East Asia, Other South America, Hong Kong, and South Korea. The EC and Eastern Europe would import slightly less lint because of lower LDC demand for their textiles.

With low LDC economic growth, projected LDC imports, even though expanding slower than under the medium assumption, would still outpace exports (because LDC production growth is cut back in the same proportion as income growth), leaving again an additional deficit for the developed exporters to satisfy.

## OUTLOOK FOR EXPORT EARNINGS

### Unit Values

#### Cotton Lint

World cotton prices, based upon SM 1-1/16 inch cotton, c.i.f., Liverpool, averaged near 30 cents (constant 1968 currency) per pound during 1965-67. The long-term trend has been downward. The expected further declines in prices of competing fibers, and the number of cotton suppliers in the world today, suggest that cotton prices will continue on a long-run downward trend, and that by 1980 they will be below their 1965-67 levels. On the other hand, the price for cotton is not likely to drop to an extremely low level since demand is projected to remain substantial and governments would intervene with policy changes or possibly some marketing arrangement.

Average 1965-67 unit values (dollars per metric ton) of cotton lint imports and exports, based upon FAO data, are shown in table 44. The unit value of Mexican exports was adjusted upward to compensate for undervaluation. 48/

The projected unit values of imports and exports for 1980, based upon a world price of 26-cents per pound for SM 1-1/16 inch cotton, were estimated by reducing each of the 1965-67 values by 13.3 percent to compensate for the 4-cent (30 to 26 cents) price decline. This method of adjustment assumes that prices of various growths and varieties of cotton would change proportionately, and that the mix of trade (varieties, staple lengths, etc.) would remain constant. Although these are oversimplifications, they should not significantly affect the magnitudes involved. The possible exceptions are regions exporting extra-long staple cotton, for which the supply-demand relationship is more distinct than for other types of cotton.

The world average unit value of cotton imports is projected to decline from \$650 per metric ton in 1965-67 to \$560 in 1980, while the export unit value is projected to drop from \$620 to \$500.

The historical and projected unit values of lint imports are higher than export unit values because of the costs of insurance and freight (difference between f.o.b. export price and c.i.f. import price).

#### Cotton Textiles

Unit values of trade in cotton textiles are more difficult to come by than those for lint trade. Most of the 1965-67 average values presented in table 44 are estimates based upon data given for volume and value of trade by GATT and for volume of trade by FAO. Those figures footnoted are not estimates but were calculated directly from the published GATT data.

The projected 1980 unit values differ from the historical period for most of the regions because of two factors: (1) low price exporters are expected to supply a larger share of the world's total cotton textile exports, and (2) apparel and other products with higher unit values are expected to account for larger proportions of cotton textile exports. To reflect the first factor, all import unit values over \$2,400 (1965-67) were lowered by 5 percent, except in the cases of the EC and Other Western Europe which were lowered by more than 5 percent so that the maximum 1980 import unit value would be \$2,500 in 1980. To reflect the second factor, all export unit values were raised 5 percent above their 1965-67 values, except for the EC and the United Kingdom, whose unit values were already above \$3,000. These two adjustments do not cancel one another out and are compatible. Although textile importing nations

48/ Unit value of exports was raised from \$380 per metric ton to \$570.

will be importing a more highly manufactured mix of products in 1980, a much greater proportion of these products will originate from exporters whose export unit values can remain well below those of the higher cost exporters, even after the former have raised unit values to compensate for more processing. Note, that in 1965-67 the unit value of LDC textile exports was \$1,190 per metric ton lower (41 percent) than the unit value of textile exports from the developed sector.

With the above changes, the projected 1980 average unit value of world cotton textile imports comes to \$2,280 per metric ton--\$70 lower than the 1965-67 estimate. The projected average value of exports is \$2,190 per metric ton--\$110 lower than in 1965-67. The difference between the two unit values again reflects marketing costs. Among the geographic regions, the unit value of textile exports from the central plan and less developed regions remains well below the level for the developed countries.

#### Export Earnings and Import Costs

##### Medium Projections

Assuming a medium rate of economic growth among the LDC's, and a 26-cent per pound price for cotton lint, LDC net earnings from trade in cotton lint and cotton textiles could reach \$1.5 billion by 1980--over \$600 million above 1965-67 estimated average earnings (table 45). All of the projected increase in LDC export earnings from cotton are shown to accrue from increased net exports of textiles, as net earnings from cotton lint are projected to decline slightly. Hong Kong, India, the UAR, South Korea, Pakistan, and Taiwan--the largest LDC cotton textile exporters in 1965-67--can be expected to provide most of the increase in LDC export earnings.

The central plan sector is projected to have a slightly lower net total cotton import cost in 1980 than in 1965-67. Increased textile imports by the USSR and lint imports by Eastern Europe will probably be more than compensated for by increased lint exports by USSR and textile exports by Communist Asia and Eastern Europe.

In the developed sector, net import costs are projected to increase to over \$1.7 billion by 1980, compared with about \$900 million in 1965-67. Most of this import cost increase will come from expansion in net textile imports by the United States and the EC (appendix table C-6 gives projections for gross trade in cotton lint and textiles for 1980).

##### Alternative Projections

The projected net value of total cotton trade in 1980 under high and low economic growth assumptions for the LDC's are presented in table 46.

High LDC economic growth.--Under the high economic growth assumption, LDC net export earnings from all cotton in 1980 is projected to be \$307 million less than under the medium growth projections. The decline in earnings would be shared more or less equally by cotton lint and textiles. The reason for the decline is that high economic growth would cause an increase in cotton consumption exceeding that of production. This would result in decreased cotton exports by many countries, and increased textile imports by the principal LDC importers. Most of the increase in textile imports will be accounted for by the East and West Africa and Other East Asia and the Pacific regions. <sup>49/</sup>

<sup>49/</sup> The projections assume that mill capacity in these regions would expand proportionately to expansion in domestic use. However, the rate of expansion under high economic growth could be greater, in which case, textile imports would be lower and net lint exports lower.

1/ A minus (-) indicates net earnings.

Sources: Appendix tables C-5 and C-6.

The central plan countries could lower their projected 1980 net import cost by \$30 million under the condition of high LDC income growth. The import cost change is mainly the result of increased textile export earnings by the Eastern European countries and the Soviet Union (recorded as a decline in net imports). The projections also indicate the developed countries would benefit from higher LDC income growth. Their combined import cost would be reduced by \$250 million because of increased cotton lint exports by the United States and increased textile exports by the Western European countries and Japan.

Low LDC economic growth.--A lower than expected economic growth rate in the LDC's would have little effect on their earnings from all cotton--net earnings are projected to increase by \$4 million. LDC textile imports would decline somewhat and total lint exports would also fall a little. Within the central plan countries, textile exports and lint imports in Eastern Europe would both fall somewhat, causing net import costs for the region to rise by \$14 million. In the developed countries, the lower LDC income would have little effect. Total import costs would increase by \$12 million, the result mainly of decreased textile exports from the United States and Other Western Europe.

## APPENDIX A

### ANALYSIS OF FIBER USE AND COTTON'S SHARE

#### Data Used

##### Fiber Use

The data used in this study on total fiber use by countries are figures on total domestic availability compiled by FAO, and are complete only up through 1964, except for a few selected countries with data through 1966 (15, 17, 18, 19, 23). In some cases, it was possible to estimate fiber availability through 1967 by using ICAC mill consumption data (World Cotton Statistics) and GATT trade data (30, 31).

FAO data have several shortcomings which FAO is working to remedy. One is the exclusion of flax and silk, and trade in certain clothing items. 1/ Another is that all fibers are aggregated on a simple weight basis, with no consideration given to manufacturing loss. For example, the simple weight of net cotton textile trade is added to domestic mill cotton use to get total cotton use, with no adjustment for the 12-percent or greater loss in weight between raw cotton going into the mill and the resulting textiles.

A third shortcoming of FAO data is the failure to convert the various fibers to a raw cotton (or some other) equivalent basis. The manmades have greater strength and durability than cotton, and thus tend to replace more than an equal weight. 2/ Thus, comparisons of consumption trends and shares among fibers may understate the importance of manmades.

Per capita fiber use levels for the various regions were calculated by dividing total fiber use by population. The population series used are those compiled by Moe (59). In many regions, 3-year running averages of per capita fiber use were used when they provided higher R<sup>2</sup>'s and more significant results. Such running averages may actually better indicate actual fiber consumption, since stock changes inherent in availability data would be leveled out.

##### Cotton's Share

Cotton's share of total fiber use for the various regions was calculated by dividing total cotton availability by total fiber availability. Again, the fact that the FAO data are not on a raw cotton or even raw fiber equivalent basis may slightly overstate cotton's share in regions with significant manmade fiber use.

---

1/ Since the completion of this study the new FAO data have become available. See (25) and appendix D for details.

2/ Examples of the raw cotton equivalent factors developed by the USDA are the following: Rayon and acetate staple, 1.10; high tenacity rayon yarn, 1.80 for 1958 to date; noncellulosic yarn not used in tires, 1.75; wool, 0.55; textile glass fiber, 1.70.

### Per Capita Income

The historical income series used were those compiled by Moe (59). Per capita GNP was used for the LDC's, per capita consumer expenditure for the DR's, and per capita net material product for the CPR's. (See details in table A-1). For analysis of some less developed regions with incomplete data, and for analysis of total world, indices of per capita income were developed from apparent growth rates.

### Cotton Prices

Spot cotton prices or Liverpool prices for particular growths were used for the major producing regions (table A-1). A world price series was developed and used for all other regions and for sector and total world analysis. The world cotton price was taken as the average of all but the highest available quotation, c.i.f., Liverpool, of the following growths of SM 1-1/16 inch cotton: United States, Mexican, Iranian, Nicaraguan, Syrian, and Greek (table A-2).

All price data used were already in U.S. currency. To reflect more accurately the price situation over time in particular countries, these prices were converted back to the country's currency at yearend exchange rates, the result was then deflated by the country's general wholesale price index, and reconverted to U.S. currency at the 1968 exchange rate. <sup>3/</sup> For multicountry regions, this process proved so cumbersome and time consuming that a less accurate conversion to constant U.S. prices was made by applying a weighted regional wholesale price index (total cotton use as a weight) directly to the undeflated price data. In cases where price indices were incomplete, the U.S. price index was used; this assumes that differences in rate of inflation between the foreign region and the United States are compensated for in the currency exchange rate--a gross assumption in light of fixed exchange rates over time.

### Manmade Fiber Prices

Wholesale list prices of polyester fibers were entered into the analysis for regions or sectors with synthetic fiber use over 5 percent (tables A-1 and A-3). For Japan, a nylon staple price series was used because a suitable polyester series was not available.

Prices were converted to constant 1968 U.S. currency in the same way as cotton prices.

Wholesale list prices of manmade fibers are deceptive because of off-list selling. However, since polyester list prices have been declining relative to those of cotton, the series was deemed meaningful. Rayon list prices were not included because of doubtful meaningfulness. Discounted rayon prices have reportedly closely followed cotton prices up and down, suggesting that cotton price, itself, may be a good proxy index for actual rayon prices.

---

<sup>3/</sup> Reasons for such a procedure are discussed by Bjarnason, McGarry, and Schmitz, American Journal of Agricultural Economics, Vol. 51, February 1969. p. 189.

1/ CE = consumer expenditure. DNI = Dom. national income. NMP = net national product. NDP = net domestic product. GNP = gross national product. For complete series, see Moe (59). 2/ Liverpool average refers to average price of available growths of SM 1-1/16 inch, see table A-2. 3/ Staple prices. For complete series used and details of deflation, see table A-2. 4/ All series deflated to constant 1968 prices by dividing by the country's wholesale price index, or in the case of a multicountry region, by a weighted index (with total cotton use as weight). Conversion to U.S. currency was done at 1968 year ending exchange rate as reported by IMF. 5/ Deflated to 1968 prices by U.S. wholesale price index. This assumes that relative difference in inflation between the particular country and the United States would be compensated for in currency exchange rates.

1/ Suitable price series for polyester staple not available. 2/ Prices in each region have been deflated to constant 1968 currency by dividing by the respective wholesale price indices, 1968 = 100. Conversion to U.S. currency also was done at 1968 exchange rates. Prices for EC are a simple average of prices in France, Italy, and West Germany. 3/ Except for the United States, the cotton price used was the average Liverpool price of SM 1-1/16 inch cotton (see table A-2) deflated to constant 1968 currency in same manner as polyester prices.

Sources: U.S. prices are from USDA publications (72, table 220; and Cotton Situation, Jan. 1969, table 11). Foreign polyester and nylon list prices are USDA/FAS compilations, mostly from Skinner's Record. Conversion to constant dollars was done by the authors.

## Analysis of Per Capita Fiber Use

### Cross Sectional Analysis

To provide a starting point for analysis, data on per capita fiber use in 1964 for the 33 regions of the study were related to the level of per capita GNP in each region. Although such cross-sectional analysis removes the influence of time per se, it does not eliminate the effect of the other factors, except as they are reflected in time.

Several analyses were run. In the first, all 33 regions were considered together, with two functions fitted to the data: semilog and log-log. Both functions had  $R^2$ 's of 0.82 to 0.84 and mean income elasticities of 0.62 to 0.65 (table A-4).

The two functions differed considerably in the use responses at other than mean incomes (table A-5). The log-log function, by its nature, resulted in a constant elasticity over all levels of incomes. For the semilog function, the elasticity began very high at low levels of income and gradually decreased to a low elasticity at high income levels.

The semilog function did not fit well at very high levels of per capita incomes, such as in the United Kingdom, Canada, and the United States (fig. A-1). If per capita fiber use in the United States is indicative of what will happen in other regions as their income increases towards that of the United States (and there seems no reason for not expecting this), then the elasticity at high levels of income is likely to be somewhat greater than that suggested by the semilog function.

In the second analysis (10 most developed regions), the USSR and Eastern Europe were combined with the eight developed regions and the two functions fitted to the resulting data (fig. A-2). The  $R^2$  values were again very close, 0.73 and 0.75, as were the mean income elasticities, 0.42 and 0.44 (table A-4). For given levels of income, the elasticities indicated by the semilog functions were higher than those indicated by the corresponding function fitted to the data for all 33 regions (table A-5).

The third analysis involved fitting the two functions to only the 27 least developed of the 33 regions, including the 23 LDR's, Communist Asia, Eastern Europe, South Africa, Japan, and Other Western Europe (fig. A-2). The mean income elasticities in each case were higher than those shown by the corresponding functions for the developed regions (table A-4). This suggests that normally the elasticity does decrease as income increases. However, the fit of the functions to the data was poorer than that found in the other analyses because of greater variation in fiber use at given income levels among the less developed regions than among the more developed.

At very low levels of income the variation in fiber use was rather substantial; for example, India and Southeast Asia had somewhat the same per capita use of fibers (fig. A-2). A major question appears to be what will be the magnitude of the response in fiber use as incomes rise in these very low income countries. Will it follow the higher response trend indicated by the UAR, Taiwan, Syria, and Turkey, or will it follow the lower response trend indicated by the Latin American regions (with the exception of Brazil) and Other West Asia? Looking at the pattern of data for all 33 regions, the higher response trend appears to fit better.

Table A-4.--Fiber use per capita related to income  
per capita, cross-sectional data, 1964

Regions included	F = a + b log I			Log F = a + b log I		
	R <sup>2</sup>	b	E	R <sup>2</sup>	b	E
All 33 regions . . . . .	0.84	8.9253 (12.9)	0.65	0.82	0.6212 (11.7)	0.62
10 most developed. . . . .	0.75	11.4965 (4.9)	0.44	0.73	.4249 (4.7)	0.42
27 least developed . . . . .	0.64	6.5565 (6.7)	0.66	0.67	.6264 (7.0)	0.63

Note: F is fiber use per capita; I is income (GNP) per capita; E is income elasticity of fiber use figured at mean values. Numbers in parenthesis are t values of the regression coefficient b.

### Time Series Analysis

Equations and variables.--Least squares analyses of regional, sector, and world time series data were carried out using one or more of the following equations:

#### Initial equations:

- (1)  $F = a + b T$
- (2)  $F = a + bI + cT$  (central plan regions only)
- (3)  $F = a + bI + cP_C + dP_S + eT$
- (4)  $F = a + bI + cP_C + dT$

#### Subsequent equations:

- (5)  $F = a + bI + cP_C + dP_S$
- (6)  $F = a + bI + cP_C$
- (7)  $F = a + bI + cP_S$
- (8)  $F = a + bI$
- (9)  $F = a + b \log I$
- (10)  $\log F = a + b \log I$

#### Where

$F$  = per capita fiber use, calendar year average.

$I$  = real per capita income, calendar year average.

$P_C$  = price of cotton, August-July average (thus providing a lead of 5 months on  $F$ ), deflated.

$P_S$  = price of synthetic fiber, August-July average (thus providing a lead of 5 months in  $F$ ), deflated.

$T$  = time trend index.

Equation 1 was run for all 33 regions. Equation 2 was employed for the three central plan regions, because fiber price data were not available and use of world price or proxy prices did not seem justified because of the degree of government intervention. Equation 3 was run for the developed sector and those regions in which synthetic fibers had a 10-percent or greater share of the market, otherwise equation 4 was used. The reasoning here was that at least this size of share would be needed for synthetic fiber prices to have any measurable effect on total use of all fibers.

The time period involved was usually 12 years, ending in 1964, 1966, or 1967, depending on availability of data. The time period was shortened to 6 to 8 years in some regions where a definite change in trend was evident.

Results.--The results of equations 3 and 4 were generally disappointing. It proved impossible in most cases to obtain any significant or conclusive measurement of the separate effects of cotton price, synthetic prices, or time trend apart from that of income. In all regions with income data, except Communist Asia and Brazil, per capita income and time were so highly intercorrelated as to confound the results. Also, cotton price and synthetic fiber price were frequently highly intercorrelated.

New equations (5, 6, and 7) were then tried with time excluded. Again, the results were disappointing. When both cotton and synthetic price series were included along with income in the analysis (equation 5), one or the other, or both, had illogical (positive) signs and were nonsignificant. When the equation included income and only one price series (equations 6 and 7), the price coefficient more frequently had a logical (negative) sign, but in all cases no significance (or even an effect on per capita fiber use of much consequence if it had been significant).

Failure to find logical relationships and significance in the multiple regressions forced final reliance on simple analysis of the effects of income (equations 8, 9, and 10). The results of these equations were generally good, with high  $R^2$ 's and correct signs (table A-6).

The developed sector, total world, and 23 of 33 regions had income coefficients from equations which were both significant and had logical (positive) signs. Unacceptable (negative) signs were encountered only for Brazil, Other South America, East and West Africa, and the less developed sector as a whole. <sup>4/</sup> Nonsignificance and very low  $R^2$ 's occurred only for Central America, the UAR, India, and Pakistan. Lack of historical income data prevented analysis for Other North Africa, Syria, Other West Asia, and Other East Asia and Pacific. Also, no analysis was made of the total central plan sector because of the diversity of development between Communist Asia and the other two regions of the sector.

The income elasticities of per capita fiber use calculated from the three simple equations were either the same or very close (table A-6). The highest responses to changes in income occurred in Iran (3.8), the Sudan (1.7 to 1.8), Communist Asia (1.7), and Hong Kong (1.2 to 1.3). The lowest significant responses were found in the USSR (0.59 to 0.62) and the EC (0.63 to 0.64).

The elasticities encountered for the DR's, with the exception of South Africa and the EC, and for Eastern Europe were higher than those found by or assumed in most previous studies. For example, the response in the United States of 1.1 was above that of the 0.47 used for projections in the NACFF study (table 10). Among the LDR's, however, no general tendency was noted for the responses to be above or below those of other studies.

The elasticities for most of the individual developed regions were higher than for the developed sector as a whole. The developed regions with the most current data also have the highest elasticities (United States, Canada, United Kingdom, and Australia-New Zealand). One explanation could be that the response (elasticity) is increasing in these regions, and the current data reflect this. However, the more current data are also more complete in their inclusion of cotton clothing imports, compared with those for the first few years in the time series. Thus, it is likely that the elasticities for these particular regions are biased upward, and that they would be lower if the time series were more comparable.

---

<sup>4/</sup> However, analysis of cotton use per capita did show significance and positive signs.

Note: F = F value; E = income elasticity of per capita fiber use, calculated at mean values.

1/ Results shown are from analysis of per capita cotton use. Elasticity was negative for per capita total fiber.

The income elasticities encountered in the time series analysis for most of the regions displayed no tendency to drop among regions with successively higher per capita income (fig. A-3). Other than for the very high elasticities of Iran, the Sudan, Hong Kong, and Communist Asia, those of all other regions ranged between 0.6 and 1.1. In fact, if there was any tendency at all among these other regions, it was for elasticity to be a bit greater, the higher the region's per capita income. Supporting this was the higher elasticity indicated for the developed sector, 0.73, compared with 0.62 indicated by the equations for the total world. Also, the elasticity of cotton use was only 0.49 for the less developed sector (suggesting that the coefficient for total fiber use may not be much, if any, greater).

#### Conclusions Regarding Elasticities

Both the time series and cross-sectional analysis suggest that factors other than per capita income play very decisive roles in both the level of per capita use and the response to changes in income. In many regions these other factors probably offset the "normal" tendency for the response to be greater at low income levels than at high. Among many LDC's the response may be tempered by severely skewed income distributions, higher textile prices relative to other prices, and more stringent restrictions on textile imports.

Among the DR's, fashion consciousness, fashion trends (including obsolescence), and technology in the form of permanent press and new uses of synthetic fibers may all contribute to higher or at least to the maintenance of the response to income changes. The greatly expanding use of carpeting, most of which is now made of synthetic fibers, may be a factor of importance in the high U.S. and Canadian elasticities encountered in the times series analysis. The above ordinary military demand created by the Vietnam struggle could also be exaggerating the U.S. response.

#### Analysis of Cotton's Share

##### Cross-Sectional Analysis

To determine the extent to which cotton's share might be related in some way to per capita income, cross-sectional data for 1964 were plotted and regressions calculated (fig. A-4 and table A-7). In the regressions, two equations were fitted, linear and semilog. The curvilinear (semilog) equation provided the best results.

Among the less developed regions, cotton's share tended to decrease the higher the region's per capita income. Among the developed regions, no relationship appeared to exist. In one analysis, including all 33 regions, and another, including only the 27 least developed of the 33 regions,  $R^2$  values were around 0.50 and regression coefficients significant (table A-7). However, a third analysis, including only the 10 most developed regions, showed no relationships between the two variables. Apparently the influence on cotton's share of increases in per capita income either diminishes to nothing, or other factors become overriding after a country reaches a certain level of development.

##### Time Series Analysis

Equations.--Least squares analyses of regional and world data on cotton's share were carried out involving one or more of the following equations.

##### All regions and world

$$(1) \quad S = a + b T$$

**Figure A-3. INCOME ELASTICITY OF PER CAPITA FIBER USE RELATED TO PER CAPITA INCOME, CROSS-SECTIONAL DATA, 1964**

# Figure A-4. COTTON'S SHARE OF FIBER USE RELATED TO INCOME

Table A-7.--Cotton's share of fiber use related to per capita income, cross-sectional data, 1964

10 most developed . . .	.06	0.0020 (0.7)	-.05	.05	6.2063 (0.6)	-.05
27 least developed. . .	.42	-0.0477 (4.2)	-.19	.47	-34.3494 (4.8)	-.21

Note: S = cotton's share; I = per capita GNP; E<sub>I</sub> = income elasticity of cotton's share. Numbers in parenthesis are t values of the regression coefficient b.

$$(2) S = a + b \log T$$

Developed regions only

$$(3) S = a + bD + cT$$

$$(4) S = a + bR + cT$$

Less developed regions only

$$(5) S = a + bD + cI$$

$$(6) S = a + bR + cI$$

$$(7) S = a + bP + cI$$

Regions with synthetic fiber share over 5%

$$(8) S = a + bD$$

$$(9) S = a + bR$$

Where:

S = Cotton's share of total fiber use, calendar year average.

T = Time trend index.

D = Difference in price (price of synthetic fiber minus the price of cotton), August-July average (thus providing a lead of 5 months on S), deflated.

R = Ratio of cotton price to price of synthetic fiber, calculated from August-July averages (thus providing a lead of 5 months on S), deflated.

P = Price of cotton, August-July average, deflated.

I = Per capita income, calendar year average.

As suggested by the cross-sectional analysis, time trend was used in the equations for the developed regions, while income was used for the less developed countries. Both could not be included because of extremely high intercorrelation.

Equations involving price differences or price ratios (3, 4, 5, 6, 8, and 9) were tried only in those regions with a synthetic fiber share over 5 percent.

Statistical results.--Results of the regression analysis were deemed acceptable for consideration when the  $R^2$  value exceeded 0.40, the overall significance level exceeded 0.05, and the coefficients had the expected signs.

The simple time trend equations (equations 1 and 2) provided generally acceptable and similar statistical results for about two-thirds of the 33 individual regions and for the developed sector and total world (table A-8). In the other regions, as well as in the less developed sector, no significant trend was evident in cotton's share. No analysis was made of the central plan sector because of the diversity of development between Eastern Europe, the USSR, and Communist Asia.

Results from one or more of equations involving price variables (D, R, or P) were acceptable for only 15 regions, or less than half. Although many of the multiple equations in these regions had fairly high  $R^2$ 's, few had both price and income or time coefficients which were significant at the 0.10 level (indicated in table A-8 by a small "a" between the  $R^2$  value and projection). In about one-sixth of the multiple equations only price was significant (indicated by a small "b") and in another one-sixth, only time or income was significant (indicated by a small "c").

In the simple regressions involving price differences (D) or price ratio (R), the former turned out to be more highly correlated with cotton's share. The coefficients in the equations were generally significant, but of course were gross in that they reflected other factors not held constant.

Equation (7), involving the simple price of cotton and per capita income, provided acceptable results in only 5 of 17 less developed regions. In many cases, there was no significant correlation; in others, the sign of the cotton price coefficient was illogical (positive). This equation was not run for the developed regions because equations with price difference or price ratio seemed more suitable. However, it was run for the developed sector, with good statistical (but poor projection) results.

Effect of price on cotton's share.--The change in cotton's share associated with changes in the price of cotton varied considerably among the five equations (table A-9). In general, the indicated effects were greater in the simple equations than in the multiple, and in the equations with a price ratio (R) as opposed to those with a price difference (D). In the multiple equations, as noted previously, there is a problem of low statistical or nonsignificance of the price and income or time coefficients.

In the simple price difference equation ( $Y = a + bD$ ), a 1-cent decrease in the price of cotton, or a 1-cent increase in the price of polyester, was associated with about a 0.1 to 0.2 percentage point change in cotton's share. This effect was constant regardless of the price difference. However, in the simple cotton/polyester price ratio equation ( $Y = a + bR$ ), the associated change in cotton's share of a 1-cent price change was greater the closer the price of polyester came to cotton. <sup>5/</sup> In the projection period, the average point change in share associated with a 1-cent decrease in cotton price ranged from 0.6 to 2.0, or up to 10 times the point change associated with a 1-cent change in the price difference.

Change in cotton's share of the magnitudes indicated by the simple price ratio equations appear unrealistically high, <sup>6/</sup> while those of the simple price difference equations may be on the low side, especially as the difference becomes smaller in the projection period (polyester prices decrease to 40 cents, while cotton prices hold constant at 30 cents).

The multiple equations also suggest that some of the price effects indicated by the simple equations may be overstated because of inclusion of effects of time trend or income. However, the frequent low level or nonsignificance of the coefficients in the multiple equations prevent any general conclusions. Also, high intercorrelations between the price variable, particularly price difference, and time or income, suggest that measurement of the separate effects may be at best very gross.

---

<sup>5/</sup> This is because the 1-cent change in price causes a larger change in the price ratio when the two prices are close together than when they are widely different.

<sup>6/</sup> Use of logarithms in calculation of the price ratio may have provided better results, but time limitations did not permit a rerun of the equations to test this out.

1/ T = time trend; D = difference--polyester or nylon price minus cotton price; R = ratio--cotton price/polyester or nylon price; I = income per capita; and, P = price of cotton. (See table A-7 for more details). Level of equation significance is not shown but was above 0.05 level for all equations with  $R^2$  values over 0.30 and above 0.01 level for  $R^2$ 's over 0.50. Significance of the individual coefficients in the multiple regressions is indicated by the following codes: a = both significant at 0.10 level; b = price variable significant only; c = income or time variable significant only. 2/ Projections from equations with a price variable assumed a constant cotton price of 30¢/lb., 8M 1-1/16 Liverpool, and a wholesale list price for polyester or nylon of 40¢/lb. 3/ "WS" indicates wrong signs on the coefficients of the variables indicated. 4/ "No analysis" (No A) performed because of inadequate data, data with clearly too much variation to provide results, or because share of synthetic fibers was under 10 percent.

## APPENDIX B

### Regional Data and Outlook Notes

#### UNITED STATES

##### Cotton Textile Use and Trade

Status of the textile industry.--The United States has by far the most capital-intensive and efficient cotton textile industry in the world. However, high wages and raw material costs keep prices up. Manmade fibers continue to make deep and rapid inroads into cotton textile markets.

Trade policy and restrictions.--Tariffs range from 9 to 23 percent on most items, with the highest rates on clothing. Kennedy Round concessions will lower the range to 7-1/2 to 21 percent. Preferential rates are given to the Philippines. Import quotas to Japan and LDC's are allocated by country and generally allow for annual average increases of 5 percent in accordance with the LTA. These import quotas agreed to under the LTA and other bilateral agreements have kept the growth of imports (as a percentage of total consumption) down since 1962.

##### Outlook

Policy changes.--Policy allowing limited import increases is likely to continue.

Textile trade changes.--Imports are likely to grow through the 1970's, but it is unlikely they will amount to more than 15 to 20 percent of total cotton textile consumption.

Cotton's share of fiber use.--This is likely to continue declining. Research, development, and promotion in the manmade sector plus the interests of the textile firms favor the continuation of present trends despite belated research and promotion by cotton interests.

##### Raw Cotton Production and Trade

Competitive status and potential production.--Production costs are relatively high (23.9 cents per pound total costs in 1966/67), competition for inputs from other commodities is high, yields are improving slowly, and potential for profitable production is good. However, Government programs supporting prices and controlling acreage limit producer responsiveness to market developments.

Production and trade policy.--Domestic needs, except for some ELS cotton, are supplied exclusively by U.S. producers, and a large share of the foreign export market is actively sought. Exports have declined in recent years because of high prices, limited stocks (brought about in part by deliberate stock reduction), and poor crops. Imports are limited by very restrictive quotas. About 125,000 bales a year, mostly ELS, are allowed in.

## Outlook

Policy changes.--None.

Production changes.--There will most likely be some revival from recent small crops, but production is extremely dependent on future Government policy.

Trade changes.--Imports will continue to be restricted. Exports will most likely increase from present low levels, but a complete revival to former high levels is unlikely as long as U.S. prices remain high.

## CANADA

### Cotton Textile Use and Trade

Status of the textile industry.--The Canadian cotton textile industry is relatively modern and efficient, but is finding it difficult to compete price-wise with imports from low-cost countries. The industry has been consolidating, and textile lines which compete with low-cost imports are being discontinued. Manmade fibers are taking a large and rapidly growing share of the market. Most of the decline in cotton's market share has been absorbed by domestic producers.

Trade policy and restrictions.--Textile exports are encouraged and have been expanding in recent years. Tariffs on imports range from 10 to 22 percent with lowest duties on yarn and the highest on clothing. Full Kennedy Round cuts have already been made. Preferential rates from free to one-half of the MFN rates are given to Commonwealth countries, including the United Kingdom, India, Pakistan, and Singapore, but not to Hong Kong. Various taxes and quantitative restrictions also inhibit imports. Under terms of the LTA, Canada does not agree to annual import increases of 5 percent.

### Outlook

Policy changes.--Policy of attempts to control import increases and to expand exports is likely to continue through the 1970's.

Textile trade changes.--Net trade was relatively constant in the 1957-64 period. Imports from low-cost countries can be expected to increase somewhat, but these will be more or less balanced by increasing Canadian textile exports.

Cotton's share of fiber use.--Cotton's share will continue to decline.

### Raw Cotton Production and Trade

Competitive status and potential production.--Canada does not produce cotton and is unable to do so.

Production and trade policy.--No restrictions are placed on raw cotton imports. Imports from major trading partners who have trade deficits with Canada (e.g., the USSR), are often encouraged.

Outlook.--No change.

## EC

### Cotton Textile Use and Trade

Status of the textile industry.--Textile industries are relatively efficient and modern. Total costs are about 10 percent below those in the United States and the United Kingdom, but the industry is beginning to feel the pinch of imports from the low-cost countries. Manmade fibers have achieved deep market penetration in the EC countries.

Trade policy and restrictions.--A common external tariff rate, ranging from 6.4 to 18 percent for most items, will be lowered to 4 to 17 percent by the Kennedy Round concessions. Highest rates are on clothing. There are no tariffs on intra-EC trade. Various taxes and quantitative restrictions are aimed at imports from Asia and Eastern Europe. The EC is a member of the LTA.

### Outlook

Policy changes.--Trade policy will continue to be directed at limiting imports from low-cost producers.

Textile trade changes.--Imports from low-cost areas will most likely continue to increase at a rate similar to that of 1953-64.

Cotton's share of fiber use.--Since cotton's share is already very low and much lower than in North America, it will probably decline at a much slower rate than it has in the past.

### Raw Cotton Production and Trade

Competitive status and potential production.--Italy produces an extremely small amount of cotton (about 10,000 bales a year), which will probably decline in the future. Production is not feasible in the other member countries.

Production and trade policy.--Policy calls for importing virtually all of the community's raw cotton needs. No restrictions are placed on imports. Low-cost producers (e.g., Turkey and Brazil) have lately been favored by buyers.

Outlook.--No changes.

## UNITED KINGDOM

### Cotton Textile Use and Trade

Status of the textile industry.--The British textile industry suffers from overcapacity, fragmentation, obsolete equipment, and high costs. Changes are being made, however, and efficiency is expected to improve. Market penetration of manmade fibers is substantial and growing.

Trade policy and restrictions.--Exports are important and encouraged by Government policy. Import tariffs range from 7-1/2 to 28 percent on most important items, but will be reduced to 7-1/2 to 20 percent by the Kennedy Round concessions. Highest rates are on clothing, lowest on

yarns. Presently, no tariffs are imposed on EFTA or Commonwealth imports, although import quotas are applied to the latter. The United Kingdom also taxes imports to compensate for taxes on domestic products. Under the terms of the LTA, the United Kingdom accepts only a 1-percent annual increase in imports from low-cost producers.

#### Outlook

Policy changes.--Recent policy changes provide for increased incentives for domestic producers to modernize and to export. In addition, the duty-free status of imports from Commonwealth countries is to be eliminated by January 1, 1972. Quotas will also be eliminated for all but central plan country imports, and the Commonwealth countries will receive a small tariff preference. Duty-free status will remain for EFTA exporters. The purpose of these changes is to limit the market penetration of imports.

Textile trade changes.--It appears that the United Kingdom will attempt to limit total cotton textile imports to about 50 percent of consumption or less. Exports may increase somewhat. In 1968, exports increased by 10 percent while imports held constant.

Cotton's share of fiber use.--As in other developed countries, cotton's share will continue to decline.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Cotton is not grown in the British Isles.

Production and trade policy.--There are no restrictions on raw cotton imports.

Outlook.--No changes.

#### OTHER WESTERN EUROPE

##### Cotton Textile Use and Trade

Status of the industry.--This region includes many diverse countries. Portugal, Spain, and to some extent Greece, are low-cost net exporters. Switzerland and Malta are also net exporters, but the other countries are net importers. The Scandinavian industries are relatively efficient but small. They cannot compete with imports from low-cost producers, so are consolidating production into those lines which are noncompetitive with low-cost imports. The Greek industry is quite underdeveloped. Both Spain and Portugal are low-cost producers and exporters, but Portugal exports much more than Spain. The Portuguese textile industry is currently plagued by overcapacity, old and inefficient equipment, and rising labor costs. Wage rates, however, still remain comparable to those in South and Southeast Asia. Most exports go to EFTA countries and Portuguese possessions in Africa. Manmade fibers have achieved high market penetration in the more developed countries of this region.

Trade policy and restrictions.--EFTA has no common external tariff. Most duties are in the 10 to 20 percent range with the highest duties on clothing. There are no tariffs on intra-EFTA trade except for Portugal, which gives preferential rates to EFTA imports. Various other taxes in

all countries also hinder imports. The Scandinavian countries have allowed relatively large quantities of low-cost imports to enter. Spain and Portugal continue to promote exports.

#### Outlook

Policy changes.--None.

Textile trade changes.--The rate of growth in Spanish and Portuguese exports is likely to slow down. Import increases in other areas should continue at present rates.

Cotton's share of fiber use.--Cotton's share will probably continue to decline, especially in the poorer countries where it still remains quite high.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Only Greece and Spain are cotton producers.

Greece is a relatively high-cost producer but high subsidies and Government production goals (500,000 bales by 1972) tend to isolate producers from world price levels. Past acreage decreases were due to the withdrawal of unirrigated land from cotton, but now 90 percent of cotton is irrigated and acreage has been stable since 1964. Government encouragement of cotton production should keep future acreage at least as high as present levels. It is likely that past yield increases are due partly to the withdrawal of unirrigated land. So, while potential yields remain high, yield increases are not likely to be as rapid as they were in the past.

Spanish producers produce for a protected home market, which isolates them somewhat from world price levels. Government policy favors the withdrawal of unirrigated land from cotton production. Recent acreage declines are due to this, but the rate of decline should decrease somewhat as the proportion of unirrigated cotton decreases. The rate of increase in yields has been influenced by the withdrawal of unirrigated land. This factor should be minimized in the future.

Production and trade policy.--Greece promotes raw cotton production and exports. Spain is becoming more dependent upon imports, but seeks to maintain some domestic production. Greece has low import tariffs. Spain has relatively high tariffs, but exporters of cotton textiles are able to import equivalent amounts of raw cotton with substantial discounts in duties. Other countries in this group have no or minimal restrictions on imports.

#### Outlook

Policy changes.--None.

Production changes.--Greek production should continue to increase somewhat while Spanish production declines.

Trade changes.--Greek cotton exports will most likely continue to increase gradually.

## JAPAN

### Cotton Textile Use and Trade

Status of the textile industry.--While synthetic textile production and exports continue to grow, cotton textile production and exports are falling, and cotton textile imports are growing. The Japanese textile industry is in the process of transforming from a cotton-labor intensive basis to a synthetic-capital intensive basis. The Government is assisting the industry to affect this transformation.

Trade policy and restrictions.--Exports are encouraged. Import tariffs range from 4.4 to 22 percent, with the highest rates on fabrics and clothing. These duties will be lowered somewhat by the Kennedy Round concessions. No preferential rates are given. In addition, various taxes and other restrictions considerably hamper the import of cotton textiles.

#### Outlook

Policy changes.--Cotton textile producers, who are facing heavy competition from lower cost Asian imports, are directing their output and exports more towards higher quality products.

Textile trade changes.--Competition in both domestic and foreign markets from lower cost Asian competitors is expected to lower or eliminate Japan's favorable trade balance in cotton textiles and to accelerate Japan's shift toward manmade fiber textile exports.

Cotton's share of fiber use.--The growth of the synthetic fiber textile industry in Japan indicates further decline in cotton's share of total fiber consumption.

### Raw Cotton Production and Trade

Competitive status and potential production.--Japan no longer finds it economical to grow cotton. It is unlikely that cotton will again be grown there.

Production and trade policy.--Policy dictates the importing of all raw cotton needs. There are no restrictions on raw cotton imports.

Outlook.--No change.

## AUSTRALIA AND NEW ZEALAND

### Cotton Textile Use and Trade

Status of the textile industry.--The Australian cotton textile industry supplies about 16 percent of the domestic market. New Zealand has no cotton textile industry.

Trade policy and restrictions.--Trade policy dictates that the bulk of Australian cotton textile needs be met by imports from Japan and other major trading partners. Tariffs on imports range from 30 to 60 percent with the highest rates on clothing. Commonwealth preferences are given

to the United Kingdom, Canada, and Ireland; and other Commonwealth countries negotiate for preferences. A special LDC preference is given on a limited number of yarn and fabric items within quotas.

#### Outlook

Policy changes.--None.

Textile trade changes.--None.

Cotton's share of fiber use.--Cotton's share is likely to continue declining.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Australian production techniques are modern and efficient, but costs are high. New dams and irrigation projects are expanding the potential cotton-growing area, and few if any alternative crops are as profitable as cotton in present growing areas. However, the high costs, lack of foreign markets, the limitation of the domestic market, and the expiration of the cotton bounty program in 1971 should all limit future acreage expansion. Due to the high levels of technology and irrigated land already used, it is doubtful if further large increases in yields are attainable.

New Zealand does not grow cotton.

Production and trade policy.--The Raw Cotton Bounty Acts provided the incentives which have made Australia self-sufficient in cotton. The cotton bounties are due to expire in 1971, but one or more states may continue with their own subsidy programs. Presently only a limited amount of short and long staple cotton is imported. Imports are duty-free, but in effect they are not allowed unless Australian ginners cannot provide the user with the desired grade of cotton.

#### Outlook

Policy changes.--The Commonwealth cotton bounty will be completely phased out by 1971, but one or more states may continue subsidizing growers.

Production changes.--Australian production will probably increase somewhat from present levels but not at anywhere near the rate of increase achieved during the past decade.

Trade changes.--Australian exports will grow somewhat as imports remain at minimal levels.

### REPUBLIC OF SOUTH AFRICA

#### Cotton Textile Use and Trade

Status of the textile industry.--South Africa has been striving for self-sufficiency in cotton textiles and by 1980 it should produce most of its needs domestically. Some textile items may still be imported for cost and/or political reasons.

Trade policy and restrictions.--Cotton textile imports face many restrictions. Tariffs average 15 percent on yarns, 14 to 17 cents per square yard on fabrics, and 20 to 25 percent on clothing. Preferential rates on fabrics are given to the United Kingdom. There are quotas on most items, import licenses, minor taxes, and a complex invoice system.

#### Outlook

Policy changes.--No changes.

Textile trade changes.--Imports should continue to decline.

Cotton's share of fiber use.--Cotton's share is likely to decline at a slower rate than in other developed countries.

#### Raw Cotton Production and Trade

Competitive status and potential production.--South Africa produces about half of her raw cotton needs with high quality cotton at prices about twice as high as lower quality imports. High costs and the limited local market are likely to cause acreage to increase at a less rapid rate during the next decade. The rate of yield increases should also decline as the rate of addition of white-owned acreage declines.

Production and trade policy.--Government policy favors the production of part of the Republic's cotton production domestically. The Government and textile manufacturers annually decide on prices to be paid for domestic cotton. Political considerations will demand some reliance on Rhodesian and Malawian cotton during the 1970's.

#### Outlook

Policy changes.--None.

Production changes.--Production will continue to increase but not as rapidly as in the recent past.

Trade changes.--An increasing amount of import needs will be met by Rhodesian and Malawian cotton.

### EASTERN EUROPE

#### Cotton Textile Use and Trade

Status of the textile industry.--Many of the East European countries, particularly Poland, Hungary, Yugoslavia, and Czechoslovakia, are emerging as important low-cost exporters. Efficiency and costs of production are difficult to determine, but it appears that export prices have little relationship to costs. The use of manmade fibers is increasing and becoming relatively important.

Trade policy and restrictions.--Exports, especially to Western Europe, are being promoted. Many importing countries complain that East European cotton textiles are exported at prices below cost. Cotton textile imports to East European countries are controlled and limited by central buying agencies.

### Outlook

Policy changes.--Efforts are being and will continue to be made to improve the efficiency of mills.

Textile trade changes.--These countries will continue to need the export income from cotton textiles, but they will also be pressured to increase their imports from LDC's.

Cotton's share of fiber use.--Cotton's share is presently quite large but it is likely to decline gradually through the 1970's.

### Raw Cotton Production and Trade

Competitive status and potential production.--Bulgaria and Yugoslavia produce relatively small amounts of cotton, but production is inefficient and has no potential for expansion. Almost all raw cotton needs are met by imports.

Production and trade policy.--Imports are controlled by central buying agencies. Czechoslovakia and Hungary impose tariffs of 5 percent MFN and 35 percent maximum.

### Outlook

Policy changes.--None.

Production changes.--Cotton production is not likely to increase and may decline.

Trade changes.--None.

## USSR

### Cotton Textile Use and Trade

Status of the textile industry.--The Soviet cotton textile industry is large and growing rapidly. Finished cotton goods are very high priced. Cotton consumption has been expanding steadily in recent years. The use of cotton is much more important than that of all other natural and man-made fibers, but the utilization of cellulosic fibers is developing rapidly.

Trade policy and restrictions.--The Soviet Union imports and exports relatively large quantities of cotton textiles annually.

### Outlook

Policy changes.--None.

Trade changes.--The Soviet Union will most likely find it necessary to import substantial amounts from the LDC's, but will not permit a trade deficit of the magnitude which would result if the trend of 1953-66 were continued.

Cotton's share of fiber use.--Despite increased competition from man-made fibers and a gradually declining share of total fiber use, cotton is likely to remain very dominant in Soviet fiber use.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Soviet cotton production is technologically advanced and relatively efficient, and is entirely under irrigation. Soil salinity is a problem in some districts. Cotton prices are set by the Government independently of world prices, but growers are apparently very responsive (elasticity = 1.0 to 2.0) to these Government prices. Most recent production increases were due to yield improvements (achieved by fertilization and reducing damages from plant diseases and soil salinity). Plenty of new cotton land is available, but future acreage increases may be minimized if manmade fibers begin to provide serious competition to Soviet cotton consumption. Maintenance of the past rate of yield increases is unlikely because of the relatively high level of modern inputs already being used and the limitations of the climate.

Production and trade policy.--Soviet Government plans call for an increase in cotton production during the next few years to 10.9 million bales.

Since 1963, Soviet cotton exports have grown from about 1.5 million bales to over 2.5 million bales. Most of the increase has come from exports to non-Communist countries, although the bulk of exports still go to East Europe. The high level of exports is maintained in part by a high level of imports, principally from the UAR, the Sudan, and other Middle East nations. Generally, imported fiber is more expensive (higher quality) than exported fiber. Besides satisfying the need for long staple fibers, USSR cotton imports facilitate Government policy of accepting available export products from other countries to balance and maintain high levels of two-way trade. Secondly, the transportation of foreign cotton to Soviet mills is often more rapid and sometimes more economical than transportation from domestic producing areas which are more than 2,000 miles from most cotton mills.

#### Outlook

Policy changes.--None. The Government will continue to encourage increased production.

Production changes.--Production will continue to increase, but less rapidly than it has in the past.

Trade changes.--Exports are not likely to increase as rapidly as they have in the recent past.

### COMMUNIST ASIA

#### Cotton Textile Use and Trade

Status of the textile industry.--Mainland China is self-sufficient in cotton textiles. It may be assumed that the efficiency of the industry is relatively low. Mill consumption has grown slowly due to a shortage of raw cotton. Despite low domestic levels of consumption, China is becoming an important low-cost exporter of cotton textiles. Cotton is the all

dominant fiber in Communist Asia's mill consumption. Manmade fibers have made little impact so far.

Trade policy and restrictions.--China is rapidly expanding cotton textile exports because of a need for foreign exchange. Export prices are thought to have little relation to production costs. Imports are tightly controlled by the state trading agency.

#### Outlook

Policy changes.--None.

Textile trade changes.--It is likely that textile exports will continue to increase but not at the rapid 1953-66 rate (which benefits from a very low base).

Cotton's share of fiber use.--Cotton's share is likely to remain very high, with only a slight decline from present levels through the 1970's.

#### Raw Cotton Production and Trade

Competitive status and potential production.--China is practically self-sufficient in cotton production. Cotton must compete with grains and other food crops, and during times of food shortages is sometimes replaced by these. Increased grain yields could free additional land for cotton. Cotton yields in China are low, but are substantially higher than in India. Yields have been increasing gradually during the past decade. Production is isolated completely from international markets and is not responsive to world price levels.

Production and trade policy.--Only minimal amounts of cotton are imported or exported. Lack of foreign exchange makes large cotton imports unfeasible.

#### Outlook

Policy changes.--None.

Production changes.--Acreage is likely to increase only slightly, if at all. Yields will continue to increase at the rate of the past decade.

Trade changes.--None.

### MEXICO

#### Cotton Textile Use and Trade

Status of the textile industry.--Mexico is self-sufficient in textiles. Its mills consume about a third of the country's raw cotton output. The domestic cotton textile industry is high-cost, operates under capacity, and produces low-grade products. Half of its equipment is relatively modern and a Government-sponsored modernization program is in process. Mexican mills generally receive the lowest grades of domestic cotton. Manmade fibers are making steady inroads in the fiber market.

Production and trade policy.--The Government provides incentives for the modernization and rationalization of the industry. Textile exports are

modest but have been growing. The Government is satisfied with fiber exports but the textile industry would like to export. Their biggest roadblock is high cost. Cotton textile imports are discouraged by tariffs averaging 110 percent plus specific duties and import licenses which are usually difficult to obtain.

#### Outlook

Policy changes.--None.

Textile trade changes.--Exports by the more efficient mills are likely to increase gradually, but not enough to reach high levels.

Cotton's share of fiber use.--Manmade fibers will continue to gradually increase their share of the market. In Mexico and in other large Latin American countries, the major textile firms have been promoting manmade textile products heavily.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Mexico is a relatively high-cost producer. In 1969/70 the weighted average total cost of production was 25.5 cents per pound. There are several alternatives to cotton in most producing areas. Acreages have declined in recent years but the desire to maintain export markets should limit future acreage declines. Past yield increases have been due to an increased and more efficient use of modern inputs and shifts of production to more suitable areas. Future yield increases are expected to be limited to those caused by changes in inputs.

Production and trade policy.--Mexico would like to maintain cotton production near 2 million bales to meet domestic needs and maintain current export markets. Government agencies promote efforts to raise yields and lower costs. The best quality cotton is exported.

#### Outlook

Policy changes.--None.

Production changes.--Output is not expected to increase during the 1970's and may decrease slightly from present levels.

Trade changes.--None.

#### CENTRAL AMERICA AND CARIBBEAN

##### Cotton Textile Use and Trade

Status of the textile industry.--The industry is growing rapidly as new and modern mills are being installed. Manmade fibers are growing in importance. Some Caribbean countries are beginning to process imported textiles for reexport.

Production and trade policy.--The CACM countries hope to achieve self-sufficiency in textile production. CACM policy is to limit production capacity to the needs of the CACM market.

### Outlook

Policy changes.--None.

Textile trade changes.--Textile imports will probably continue to decrease, and are likely to be eliminated by 1980.

Cotton's share of fiber use.--Cotton's share will decline gradually.

### Raw Cotton Production and Trade

Competitive status and potential production.--Central America is a high-cost area. About 90 percent of its production is exported, but only Nicaragua is highly dependent upon cotton exports. Weighted average total costs for Central American (1967-68) are 26 cents per pound. Acreage increases before 1966 were due to boom conditions. Rising costs and insect problems have prompted much diversification out of cotton. On a limited acreage, cotton is potentially the most profitable crop and in the long run cotton can be expected to remain on this acreage, but acreage cannot be expected to reach again the high levels of the mid-1960's. Little of the crop is irrigated and insect infestation remains a serious problem, so no great yield increases, as in the past, can be expected. However, some yield improvement can be expected as better insect control is achieved and more farms are consolidated in the hands of the more efficient producers.

Production and trade policy.--Inefficient producers are discouraged, diversification from cotton is encouraged, and the Governments conduct only a limited amount of research into new varieties and inputs. The Governments regulate planting dates and stubble clearance. Banks and input suppliers assist in the implementation of Government production policies. No subsidies are given. The Governments assist in export promotion.

### Outlook

Policy changes.--None.

Production changes.--Production should increase slightly from recent levels by 1980.

Trade changes.--Slightly larger proportions of future production will be utilized domestically.

## BRAZIL

### Cotton Textile Use and Trade

Status of the textile industry.--Brazil is self-sufficient in cotton textiles. The industry faces many problems--managerial, technical, and structural. The per capita consumption of textile products is low and declining. Synthetic fibers offer increasing competition to cotton.

Production and trade policy.--The Government is offering the cotton textile industry incentives to modernize. Textile imports are effectively discouraged by very high import duties and other restrictions. Attempts are being made to expand textile exports, which are of minor importance.

## Outlook

Policy changes.--None.

Textile trade changes.--Cotton textile exports by some of the more efficient firms are likely to expand somewhat, but the prospects for high levels of exports are very limited.

Cotton's share of fiber use.--As in other important Latin American countries, the textile industry is strongly promoting the increased use of manmade fibers. Their use should increase greatly during the next decade.

## Raw Cotton Production and Trade

Competitive status and potential production.--Brazil is a low-cost producer of cotton and production has increased greatly (about 50 percent) over the past 3 years. About a quarter of the crop grown in the North is of a perennial variety and is very unresponsive to price changes. In the South, where the remaining three-quarters of the crop is grown, total production costs averaged about 16.3 cents per pound in 1968/69. Farmers have good alternative crop potentials but are presently very satisfied with returns from cotton. All of the recent increases in cotton production have been in the South. Marginal land recently entered into cotton production may not remain in cotton, but total future acreage should decrease little from present levels as more western and State of Parana lands come into production. Future average yield increases will probably be at a rate similar to past increases. Recent yield increases have been due to an increased portion of the crop being grown in the South where yields are higher but a heavier use of modern inputs should speed up future rate of yield increases in the South, so that the rate of yield increase in all of Brazil during the 1970's will match that of the 1960's.

Production and trade policy.--Production is much more dependent upon the price of peanuts, corn, and other alternative crops than upon Government policy. Cotton export markets are sought in the major importing countries.

## Outlook

Policy changes.--None.

Production changes.--Production will probably continue to increase but not at anywhere near the extremely rapid pace of the past few years.

Trade changes.--Gradual increases in exports can be expected.

## COLOMBIA

### Cotton Textile Use and Trade

Status of the textile industry.--Colombia, self-sufficient in textiles, has the most modern and efficient cotton textile industry in Latin America. The use of manmade fibers has been increasing rapidly.

Production and trade policy.--Government policy encourages the constant modernization of the textile industry by a liberal capital goods import policy. Government and industry efforts to promote exports have been rewarded by constant increases in exports. Textile imports are effectively discouraged by very high tariffs and other import restrictions.

#### Outlook

Policy changes.--Restrictions on imports from Andean Group partners may be liberalized.

Textile trade changes.--Exports have good prospects of continued gradual increases. Trade (both exports and imports) with the other Andean Group countries is likely to increase.

Cotton's share of fiber use.--The two dominant textile firms are conducting apparently successful promotional campaigns to increase the public's acceptance of manmade fibers.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Cotton production has almost doubled within the last few years. Presently, about half of Colombia's cotton production is exported. Production costs are relatively high (23 cents per pound in 1968/69), and farmers are considered to be price responsive. There are good alternative land uses, but most cotton farmers are presently satisfied with returns from cotton. Recent acreage increases have been due, in part, to Government incentives to produce "secondary exports." But production problems have multiplied recently, and acreage should stabilize near or below present levels as production problems manifest themselves. Future yield increases are not likely to be as rapid as in the past as the factors that accounted for past increases (switch to more modern inputs) become less important, and production problems (e.g., insect infestation) become worse than at present.

Production and trade policy.--Government assistance to cotton farmers is through technical advice, the development of new varieties, subsidized credit in kind and a 15-percent tax rebate on cotton exports.

#### Outlook

Policy changes.--The Government can be expected to do what is necessary to retain newly obtained cotton export markets.

Production changes.--Production is likely to increase only slightly if at all from present very high levels by 1980.

Trade changes.--Exports may increase to some of Colombia's new Andean Group partners, especially Chile.

### PERU

#### Cotton Textile Use and Trade

Status of the textile industry.--The cotton textile industry is growing and presently meets most of the country's needs. Many producers are very inefficient. Manmade fibers are capturing an increasing share of the textile market.

Production and Trade Policy.--The Peruvian cotton textile industry will continue to expand to obtain greater self-sufficiency. Textile imports face high tariff barriers.

Outlook

Policy changes.--None.

Textile trade changes.--Imports will continue to decline as the country becomes even more self-sufficient in textiles.

Cotton's share of fiber use.--Cotton's share will continue to decline.

Raw Cotton Production and Trade

Competitive status and potential production.--Cotton is produced on irrigated land and expansion potential is limited. Average total production costs are high (26 cents per pound), but the long and extralong staple varieties command high prices. In some areas alternative crops are limited, but recent trends in the Tanguis cotton area (two-thirds of Peru's cotton) indicate relatively high price responsiveness by producers and a willingness to switch to alternative crops. Total cotton acreage is unlikely to reach the high levels of the early 1960's again, but cotton is an important export commodity. Acreage should increase from present low levels as more irrigation water becomes available and insect control problems are resolved. Recently, yields have been declining because of poor weather and insect problems. Yield potentials, possibly with new varieties, improved efficiency in the use of irrigation facilities, and improved insect control are much greater than those currently being achieved.

Production and trade policy.--Government policy includes increasing agricultural land on the coast (where cotton is grown) by irrigation projects. A new canal in the North Coastal region is expected to increase the area in ELS cotton. The Government has recently liberalized both import duties on agricultural raw material and taxes on cotton production. These should help producers to meet foreign price competition.

Outlook

Policy changes.--None.

Production changes.--By 1980, production should recover somewhat from present low levels.

Trade changes.--None.

OTHER SOUTH AMERICA

Cotton Textile Use and Trade

Status of the textile industry.--Argentina and Chile are self-sufficient in cotton textiles. The remaining nations in this group produce substantial portions of their cotton textile needs. Industry efficiency varies,

but on the whole it is relatively low. Cotton textiles face heavy competition from manmade fibers, especially in the wealthier countries. In Chile, cotton consumption is increasing very slowly because most of the increase in demand for textiles is being met by manmade fibers. In Argentina, cotton consumption is declining because of the heavy competition from synthetics and declining real wages.

Production and trade policy.--Domestic markets for cotton textiles are heavily protected. Few concessions are given to LAFTA textile exporters, but some liberalization in trade among Andean Group countries is expected. Many of the smaller countries hope to enlarge their cotton textile industries in order to supply greater percentages of their domestic markets. Textile exports to countries outside the LAFTA region are not anticipated.

#### Outlook

Policy changes.--None.

Textile trade changes.--Total imports are likely to decline over the next decade. An increased proportion of total imports will be from other LAFTA countries.

Cotton's share of fiber use.--Cotton's share will continue to decline, especially in the wealthier countries like Argentina, Chile, and Venezuela.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Chile and Uruguay must import all or most of their raw cotton needs. The remaining nations in their group grow all or the greater part of their domestic raw cotton needs. Argentina accounts for about three-quarters of the cotton grown in this region. Production in Argentina and the other countries is relatively inefficient. Acreage in Argentina is not expected to decline as rapidly as it has been. Recent price increases have stabilized acreage. Gradual yield increases are expected to continue, but the relative unimportance of cotton cultivation and the stagnant demand indicate that little emphasis will be placed on the application of new yield-improving inputs. Similar conditions apply to the other cotton producers in the region.

Production and trade policy.--Argentine cotton policy has had the objective of maintaining self-sufficiency in the crop. The remaining producers, especially Ecuador and Venezuela, hope to obtain self-sufficiency. Most of these countries tax the import of raw cotton, but grant substantial preferences to other LAFTA members. Chile's principal suppliers are Mexico, Peru and Brazil.

#### Outlook

Policy changes.--None.

Production changes.--It is likely that by 1980 Ecuador and Venezuela will have achieved self-sufficiency in cotton production.

Trade changes.--None.

## EAST AND WEST AFRICA

### Cotton Textile Use and Trade

Status of the textile industry.--Cotton textile industries in East and West Africa are mainly based on import substitution in local markets. In most cases, production is high-cost and inefficient. Manmade fibers have only a small share of the textile market. This share will increase gradually. The largest cotton textile industries are in Nigeria, Congo (K), and Uganda. Nigeria accounts for almost a third of the cotton textiles produced within the region. Trade restrictions imposed during the recent civil war induced large production increases in the Nigerian cotton textile industry. Mill consumption of cotton has been increasing in the Congo (K), but efficiency is hurt by antiquated machinery and methods. The principal mills operate at less than optimum capacity. Uganda is nearly self-sufficient in cotton textiles and would like to develop export markets.

Production and trade policy.--Most cotton textile producing countries in this region are still attempting to develop industries based on import substitution. Import barriers in these countries are high, but competition from low-cost East Asian producers continues to pose difficult problems. Some raw cotton exporters have aspirations to export cotton textiles in the future.

#### Outlook

Policy changes.--Trade barriers will continue to go up as more countries begin to develop cotton textile industries.

Textile trade changes.--Cotton textile imports will decline as local industries develop. The outlook for textile exports is not good.

Cotton's share of fiber use.--Cotton's share should remain very high but will decline somewhat as the use of manmade fibers increases.

### Raw Cotton Production and Trade

Competitive status and potential production.--Cotton production is quite inefficient, but input costs (principally labor) are quite low and in many countries and regions there are few alternative crops. Acreage and yield statistics are generally unreliable for most countries, thus 1980 production projections were based on past production, not on acreages and yields. It is expected that most regions will increase production over the next several years. Changes are expected to be very gradual with some expansion in acreage, especially among the most minor producers, and some improvements in technique--leading to increased yields. The demands of local textile mills spur production in some countries.

Production and trade policy.--Most producing countries seek to expand production to gain increased foreign exchange, or to save foreign exchange by supplying their own textile mills.

#### Outlook

Policy changes.--None.

Production changes.--Production should continue to increase gradually during the next decade.

Trade changes.--Raw cotton importers should become increasingly self-sufficient. Total exports from the region will increase very gradually.

#### UNITED ARAB REPUBLIC (EGYPT)

##### Cotton Textile Use and Trade

Status of the textile industry.--Egypt is self-sufficient in cotton textiles, and is a major low-cost exporter. Most exports go to central plan countries and to other Arab countries. The industry has been expanding rapidly since the early 1950's, but currently faces many problems because of the lack of capital for machinery and spare parts imports, and inefficient labor use. Manmade fiber use is unimportant and is unlikely to increase significantly during the next decade.

Trade policy and restrictions.--The Government actively promotes cotton exports. Cotton textile imports are prohibited.

##### Outlook

Policy changes.--None.

Textile trade changes.--Exports are likely to increase gradually.

Cotton's share of fiber use.--Cotton's share is unlikely to decline significantly.

##### Raw Cotton Production and Trade

Competitive status and potential production.--The UAR is an efficient producer of cotton and the world's largest supplier of long and extra-long staple fibers. The Government sets the acreage and farm price, isolating the growers from prices on world markets. There are few alternative export crops. Future acreage is expected to stabilize near 1969 levels. It should not expand much beyond this point because of the demand for competing crops--rice, corn, and wheat. Future yield increases are expected to be moderate, slightly less than the rate of increase achieved in the recent past, because the adaptation of new inputs is not likely to be as rapid as it has been.

Production and trade policy.--The Government hopes to maintain production near the 1969/70 level, but above the lower level of recent years. Long-range goals emphasize stabilization of cotton production and expansion of food crop production. Cotton export policy takes maximum advantage of the high quality of Egyptian cotton. Cotton imports are prohibited.

##### Outlook

Policy changes.--None.

Production changes.--By 1980, production should be slightly higher than current levels.

Trade changes.--None.

## SUDAN

### Cotton Textile Use and Trade

Status of the textile industry.--The cotton textile industry has grown rapidly since 1960. Consumption has increased from 5,000 bales in 1960 to 65,000 bales in 1968. A large proportion of domestic cotton textile demand is now met by domestic production, but the industry finds it very difficult to meet foreign competition. Manmade fibers are of no importance.

Trade policies and restrictions.--The eventual elimination of the need for textile imports is foreseen. Textile imports are controlled.

#### Outlook

Policy changes.--Tighter restrictions on textile imports are probable before 1980.

Textile trade changes.--Textile imports will probably be eliminated by 1980.

Cotton's share of fiber use.--The use of manmade fibers is likely to remain very insignificant.

### Raw Cotton Production and Trade

Competitive status and potential production.--Cotton production has been increasing steadily because of increased acreage. Most production consists of long and extralong staple cotton. About 75 percent of cotton cropland is irrigated. Growers are isolated from world market trends by Government regulations regarding acreage, prices, etc. There are few alternative export crops. Acreages should continue to trend upward, but competition from other crops, like peanuts and wheat, should keep acreage from increasing as fast as in recent years. Yields have been stagnant, but there is potential for much greater yields than those currently obtained. Increases should come as farmers learn new techniques and as more modern inputs are used. A developing labor shortage should speed the use of new inputs.

Production and trade policy.--The Government is attempting to teach some farmers newer techniques. There is a growing feeling that future prospects for medium staples will be better than those for the longer staples. Government technicians are experimenting in new varieties. Efforts are being made to diversify, but no good alternative to cotton production has yet been found. About a quarter of cotton exports are under bilateral agreements.

#### Outlook

Policy changes.--None.

Production changes.--Production will continue to increase by substantial amounts.

Trade changes.--None.

## OTHER NORTH AFRICA

### Cotton Textile Use and Trade

Status of the textile industry.--Textile industries in these North African countries are growing very rapidly, but they still do not meet all of their needs for cotton textiles. Morocco has the largest cotton textile industry in the region, and Algeria's industry is the fastest growing. Algerian raw cotton imports increased more than fourfold from 1964 to 1967. Many mills are modern and are probably relatively efficient. Manmade fibers are not yet important but their use will probably grow gradually through the 1970's.

Trade policies and restrictions.--The principal policy is the development of local industries to substitute for imports. These policies are aimed at developing self-sufficiency in cotton textiles.

### Outlook

Policy changes.--None.

Textile trade changes.--Imports will continue to decline at a relatively rapid rate through the 1970's.

Cotton's share of fiber use.--Cotton's share will remain high despite some increased market penetration by manmade fibers.

### Raw Cotton Production and Trade

Competitive status and potential production.--Most of the cotton in these countries is grown in Morocco. A small amount is also grown in Algeria. Most of the production is long-staple. About half of this is exported, and medium staple cottons are imported.

Production and trade policy.--Morocco exports about half of its long-staple cotton production and imports cheaper staples for domestic use. Algeria is apparently attempting to increase cotton production to supply a larger proportion of national needs.

### Outlook

Policy changes.--None.

Production changes.--The region will probably increase its production somewhat.

Trade changes.--None.

## IRAN

### Cotton Textile Use and Trade

Status of the textile industry.--Iran is nearly self-sufficient in cotton textiles. The industry has grown rapidly since 1957 and is quite modern.

Efficiency, although poor, is improving. Manmade fibers are presently of minor importance, but their use has increased rapidly in recent years.

Trade policy and restrictions.--Only the import of specialized textiles is permitted. Tariffs are about 25 percent of value. Cotton textile exports are not promoted or foreseen.

#### Outlook

Policy changes.--None.

Textile trade changes.--Imports will continue at a very low level.

Cotton's share of fiber use.--Cotton's share will decline somewhat, but cotton will remain dominant.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Iran is a relatively low-cost cotton producer. Average total cost per pound in 1968/69 was about 21.2 cents. Cotton quality is high and about two-thirds of the crop is exported. Production technology has been advancing with improvements in wells for irrigation, land leveling, mechanical land preparation, and aerial insecticide application (Government subsidized). Very little fertilizer is used. The Ministry of Agriculture controls acreage and regions of production. However, despite Government encouragement of cotton production, acreage has changed little since 1961, and labor shortages and competition from food crops may keep acreage from expanding as much as the Government desires. Further use of modern inputs and improved management techniques are expected to contribute to a faster rate of yield increase than was achieved during the 1959-68 period.

Production and trade policy.--The 1968-73 development plan anticipates increases in acreage and yields to raise production to 1,000,000 bales by the later year. Cotton is the second most valuable export commodity (oil is number one), and the Government encourages and to some extent subsidizes its production and export.

#### Outlook

Policy changes.--None.

Production changes.--Moderate increases through the 1970's.

Trade changes.--Moderate increases in exports.

### SYRIA

#### Cotton Textile Use and Trade

Status of the textile industry.--Syria is nearly self-sufficient in cotton textile production. Some two-way trade in textiles is carried on with neighboring countries. The industry is quite inefficient and the Government lacks the resources to modernize it. Rayon consumption is high, but the use of other manmade fibers is not important.

Trade policy and restrictions.--All foreign trade is controlled by the Government and it can be assumed that it would not allow large quantities of cotton textiles to be imported. The Government would like to export textiles in the future, but high costs, low quality, and limited capacity make significant exports unlikely.

#### Outlook

Policy changes.--None.

Textile trade changes.--None.

Cotton's share of fiber use.--Cotton's share is likely to decrease only gradually.

#### Raw Cotton Production and Trade

Competitive status and potential production.--The Syrian economy is very dependent upon cotton exports. Domestic use of cotton counts for a relatively unimportant proportion of the crop. Syria is a relatively high-cost producer of cotton, but there are no important alternative export crops. Acreage has been somewhat stable since 1966. The economy's dependence upon cotton necessitates at least the maintenance of present acreage. The completion of a new dam on the Euphrates River (the first phase is to be completed in 1973) could allow substantial expansion of cotton acreage.

Yield increases are not likely to be as rapid as they were in the 1959-68 period because the principal factors that accounted for those increases (more modern inputs) are no longer as operative, and substantial production problems are now becoming apparent.

Production and trade policy.--The 1966-70 development plan proposed a one-third increase in production over the 5 years, but by 1969 the production increase was minimal. Cotton production increases were to be obtained by yield improvements, not acreage expansion. Exports, of course, are promoted. A limited quota of ELS imports is allowed.

#### Outlook

Policy changes.--None.

Production changes.--Cotton production will increase through the 1970's.

Trade changes.--None.

### TURKEY

#### Cotton Textile Use and Trade

Status of the textile industry.--Turkey is self-sufficient in cotton textiles, and exports are of minor importance. The industry is long established, growing, and appears to be relatively efficient. The private sector of the industry (two-thirds of production) actively seeks new techniques, products, and markets. Manmade fibers have captured a small but rapidly growing portion of the market.

Trade policy and restrictions.--Textile imports have been effectively excluded. Some mills are interested in exporting textiles, but the Government appears to be satisfied with fiber exports.

Outlook

Policy changes.--None.

Textile trade changes.--Cotton textile exports should increase gradually.

Cotton's share of fiber use.--Cotton's share will decline gradually.

Raw Cotton Production and Trade

Competitive status and potential production.--Turkey is an efficient producer of relatively low-quality cotton. About two-thirds of the crop is exported. There are good alternative crop opportunities, especially fruits and vegetables, which can be exported to the EC. This potential for alternative crops is expected to be the principal factor behind future cotton acreage stagnation or declines. The rate of yield increase has slowed since 1964. Future yield increase can be expected to be relatively moderate, compared with 1959-68 trend. This is mainly because the rate of improvements in practices and shifts to irrigated acreage is likely to slow down.

Production and trade policy.--The Government provides some technical aid to producers and sets minimum prices shortly before harvest time. The Government assists in export promotion. A limited import quota of long-staple cotton is allowed.

Outlook

Policy changes.--None.

Production changes.--Production may increase somewhat from present levels as yields continue to improve.

Trade changes.--None.

OTHER WEST ASIA

Cotton Textile Use and Trade

Status of the textile industry.--This is a diverse group of countries whose cotton textile industries are in various states of development. The region still must import part of its textile needs, but the capacity of local industries is expanding relatively rapidly. The use of manmade fibers is gaining rapidly in some countries of the region.

Trade policy and restrictions.--Policies vary widely from country to country. No one country dominates the area.

Outlook

Policy changes.--None.

Textile trade changes.--Imports are likely to decline, but some of these countries will continue to import a portion of their needs from their neighbors and low-cost exporters. Most exports originate in Israel, but high labor costs and a strong domestic demand should prevent these from rising very rapidly.

Cotton's share of the fiber market.--Cotton's share will decline gradually.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Cotton does not play an important role in the economies of these countries. Israel produces over two-thirds of the region's cotton with very modern techniques. Part of the crop is exported, but most is utilized domestically. The limitations on irrigated land and competition from other crops should prevent acreage in all of the region's countries from increasing faster than it has in the past. Yields have been stable since 1964. Israel has already achieved very high yields, and further large yield increases there are unlikely.

Production and trade policy.--Cotton production is promoted to supply domestic needs and, in the case of Israel, an additional small surplus for export.

#### Outlook

Policy changes.--None.

Production changes.--Production will increase gradually through the 1970's.

Trade changes.--None.

### INDIA

#### Cotton Textile Use and Trade

Status of the textile industry.--India's cotton textile industry, the second largest in the non-Communist world, is plagued by antiquated machinery, "sick mills" (inefficient, money-losing mills), and rising production costs. India has not been able to fill its U.K. textile quota in recent years, and Indians fear that the new U.K. tariff (1972) will cut exports to that country (one-third of total exports) by 65 percent. However, modernization and expansion of the industry is continuing, and 90 percent of production is still sold domestically. The synthetic fiber industry is growing rapidly, but still only accounts for about 10 percent of total cloth production.

Trade policy and restrictions.--The Government has a program to assist the textile industry to modernize and to rehabilitate the "sick mills." Exports have been subsidized as of April 1968. Cotton textiles are not imported.

## Outlook

Policy changes.--The Government will probably be forced to increase its efforts to assist the industry to modernize. India cannot afford continued losses in its important cotton textile exports because of inefficiency in the industry.

Textile trade changes.--Trade is likely to be maintained near current levels, but the new U.K. tariff may make this difficult.

Cotton's share of fiber use.--Manmade fibers will continue to make gradual inroads, but cotton will remain dominant in the market.

## Raw Cotton Production and Trade

Competitive status and potential production.--India grows about 90 percent of her raw cotton needs, and is the fourth largest producer of cotton in the world. Very low yields per acre, however, indicate that production is rather inefficient. Heavy competition from food crops for the land should prevent acreage from increasing above current levels during the next decade. Yields, however, are likely to rise above the gradual upward trend of the last decade. The reason is the economy's dependence upon a large domestic cotton crop to supply growing mill needs, and unwillingness to divert food acreage to cotton. This will necessitate increased inputs into improved techniques and the use of more modern inputs. Cotton yields are starting from a very low base and could easily increase faster than they have been.

Production and trade policy.--The Government has recently adjusted cotton policy in an attempt to increase production. The minimum support price was raised by 5 percent and regulations restricting the internal movement of cotton have been abolished. Long-range goal is to become self-sufficient by increasing yields while maintaining acreage. However, a policy to grow more long-staple needs domestically has been unsuccessful, mainly because producer prices were set too low. Tariffs on cotton imports are low but import regulations are very strict. P.L. 480 imports are important.

## Outlook

Policy changes.--Policies aimed at increasing yields will be more strongly emphasized.

Production changes.--Production, through the 1970's, will increase at a more rapid pace than it did in the 1960's.

Trade changes.--Imports are likely to decrease somewhat, but long staple imports will continue to be necessary.

## PAKISTAN

### Cotton Textile Use and Trade

Status of the textile industry.--Pakistan is a major low-cost exporter.

The textile industry grew rapidly through the 1950's, more slowly in the 1960's, and is presently suffering from underutilized capacity. Production is relatively inefficient but very low wages keep costs down. Quality control on export items is a problem. The Government has given top priority to the modernization of the industry and is encouraging the use of unutilized capacity via a capacity tax.

Trade policy and restrictions.--The Government favors textile exports over raw cotton exports. Incentives are given to cotton textile exporters in the form of bonus vouchers. The Government feels that the new U.K. tariff (1972) will adversely affect its cotton textile exports. Textile imports are tightly restricted.

#### Outlook

Policy changes.--None.

Textile trade changes.--Textile exports may gradually rise above current levels, but the new U.K. tariff (1972) will make the task difficult.

Cotton's share of fiber use.--The inroads of manmade fibers will continue to be very minimal.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Cotton is grown almost entirely on irrigated land in West Pakistan. Production costs are low (20.1 cents per pound average total cost), but returns per acre are small because of low yields. Primitive cultural practices and low-potential varieties have kept yields down, but the acceptance of new techniques and inputs in limited areas has permitted average yields to increase very gradually through the 1960's. More widespread application of modern practices may help yields to increase a little more rapidly through the 1970's. Increased competition from other crops is expected to cause a leveling off of cotton acreage after 1970.

Production and trade policy.--Government policy is based on increasing production through technical assistance to farmers while maintaining acreage near present levels. Both raw cotton and cotton textile exports are considered to be important foreign exchange earners which must be increased.

#### Outlook

Policy changes.--None.

Production changes.--Production is expected to continue increasing rapidly, although not as rapidly as it did during 1958-68. Future increases will come mostly from increased yields.

Trade changes.--Exports are expected to increase gradually.

#### OTHER SOUTH ASIA

##### Cotton Textile Use and Trade

Status of the textile industry.--This region is dependent upon imports for

more than half of its cotton textile needs. Most of the area's cotton textile manufacturing capacity is accounted for by Afghanistan's small but modern industry. Afghan textile producers have trouble competing with imported textiles. A small quantity of rayon textiles is produced in Afghanistan.

Trade policy and restrictions.--Afghanistan has no present intention of exporting cotton textiles. Textiles which compete directly with domestic products are not allowed to be imported.

#### Outlook

Policy changes.--None.

Textile trade changes.--This region will continue to be a textile importer.

Cotton's share of fiber use.--Cotton's share is not likely to decline much, if any.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Afghanistan produces almost all of this area's cotton. About half of the annual production is exported to the USSR (some for reexport) and most of the rest is used domestically. Cotton is an important foreign exchange earner. Growing conditions are not particularly favorable, and producer prices are low, so it is not likely that acreage will increase above the level it has maintained since 1963. Yields have been trending downward, but they were often over 200 pounds per acre in the late 1950's and early 1960's. It should be possible to approach similar yields on a regular basis by 1980.

Production and trade policy.--The Government of Afghanistan encourages cotton production to meet demands for the domestic textile industry and for foreign exchange.

#### Outlook

Policy changes.--None.

Production changes.--Production should increase gradually as more farmers begin to use modern yield-improving techniques.

Trade changes.--None.

#### SOUTH EAST ASIA

##### Cotton Textile Use and Trade

Status of the textile industry.--This region is expanding its cotton textile production, but remains highly dependent upon imports to satisfy its needs. About two-thirds of the area's cotton textile production is concentrated in Thailand. Thailand's cotton textile industry has grown rapidly during the past decade. Most of its equipment is quite modern and apparently is efficiently operated. Manmade fibers have gained a relatively important and growing share of the market.

Trade policies and restrictions.--The cotton textile industries of Thailand and her South East Asian neighbors are intended to produce almost exclusively for domestic consumption. The Thai Government protects the domestic industry by tariffs on items which compete with domestic produce. In 1965, the ad valorem tariff was 32 percent on these items.

Outlook

Policy changes.--None.

Production changes.--Production will continue to increase, but more gradually than it has over the past decade.

Trade changes.--Imports may decline slightly.

Raw Cotton Production and Trade

Competitive status and potential production.--In 1968/69, Thailand produced two-thirds of the region's cotton, but due to a drastic drop in acreage, its 1969/70 average is estimated to be less than half the region's total. Burma and Cambodia produce the remainder of South East Asia's cotton. Production throughout the area is primitive and inefficient, but increasing numbers of Thai farmers are adopting more modern techniques that have increased average yields there. Yields in Burma and Cambodia are much lower than in Thailand. The drastic Thai acreage decline in the 1969/70 season was reportedly due to credit agencies being reluctant to extend credit to many producers who were unable to pay their entire accounts from the previous season. South East Asian cotton acreage is not expected to rise much during the 1970's because of the strong competition from other crops and the relative inefficiency of cotton production. Yields are currently running ahead of the 1959-68 trend and can be expected to remain there. Minor changes in inputs or techniques should have appreciable impact on yields (as they have in the past).

Production and trade policy.--Thailand would like to reduce dependence upon imported cotton. The Government has encouraged cotton production through its emphasis on farm diversification.

Outlook

Policy changes.--None.

Production changes.--Production will increase gradually as yields improve.

Trade changes.--The region will continue to be partially dependent upon imported cotton.

HONG KONG

Cotton Textile Use and Trade

Status of the textile industry.--Hong Kong is a major low-cost exporter of cotton textiles. Its industry is modern and very efficient, but its growth has slowed recently because of a labor shortage and the heavy competition from manmade fibers. The textile industry is becoming more capital intensive and is shifting heavily toward the production of synthetics and cotton-synthetic blends. The import of textiles for processing and reexport is very important in Hong Kong.

Trade policy and restrictions.--In response to world demand, the industry is shifting more to cotton-synthetic blends in its textile products. Hong Kong is a free port so there are no restrictions on imports or exports of textiles.

Outlook

Policy changes.--None.

Textile trade changes.--All cotton textiles will become less important in Hong Kong's exports.

Cotton's share of fiber use.--Cotton's share will continue to decline.

Raw Cotton Production and Trade

Competitive status and potential production.--Hong Kong does not produce cotton.

Production and trade policy.--There are no restrictions on raw cotton imports.

Outlook.--No changes.

SOUTH KOREA

Cotton Textile Use and Trade

Status of the textile industry.--Although a relative newcomer, South Korea is an important low-cost exporter of cotton textiles. Exports of total textiles and clothing have increased from about \$27 million in 1964 to \$173 million in 1968. During this time, clothing exports have increased much more rapidly than other textiles, and manmade and blended textile-product exports have increased much faster than cotton textile exports. Despite the importance of exports, the cotton textile industry is principally dependent upon the domestic market. However, the domestic market is growing rather slowly, and although cotton is expected to retain its leadership in the market, the demand for manmades has been increasing much more rapidly than the demand for cottons. The cotton textile industry is plagued by old and obsolete equipment and dependent upon subsidies to maintain exports, but hopes to remedy some of the inefficiencies by a modernization program.

Trade policy and restrictions.--The Government encourages textile exports by a program of subsidies for textile exporters. These include interest rate concessions, tax exemptions, lower tariffs and other raw material import assistance, and concessional rail and electric power rates. Cotton and synthetic fabrics apparently get the highest subsidies. These subsidies are in part negated, however, by the overvaluation of Korean currency (as of November 1969). The domestic market is protected from imports, and domestic prices for cotton textiles are apparently higher than export prices.

Outlook

Policy changes.--None.

Textile trade changes.--Manmades will account for an increasing percentage of textile exports.

Cotton's share of fiber use.--Cotton will maintain its top rank in the market, but its share of the market will decrease rapidly.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Only small amounts of cotton are presently grown in South Korea, but the country has cotton-growing potential. In 1945, undivided Korea produced 289,000 bales of cotton, compared with 25,000 bales in the two Koreas in 1969. Cotton is presently not grown because grain production is considered more profitable, and imports from the United States under P.L. 480 and CCC concessional terms make local production uneconomic.

Production and trade policy.--Agricultural policy favors the import of cotton. There is a low tariff on cotton imports, but this is waived if the importer exports cotton textiles.

Outlook.--No changes.

### TAIWAN

#### Cotton Textile Use and Trade

Status of the textile industry.--Taiwan's cotton textile industry, an important low-cost exporter, has been rapidly expanding production and exports in recent years. Apparently the industry is relatively efficient, but is burdened by numerous small-scale mills with insufficient capital. However, a continuous effort to modernize has increased efficiency and improved product quality. Japanese textile interests are active in the expansion and modernization of Taiwan's industry, especially in manmade fibers. Manmade fiber production is low but is expanding much more rapidly than cotton.

Trade policy and restrictions.--Government policy encourages the export of textiles, the diversification of export markets, and the modernization of the industry. Cotton textiles are not imported.

#### Outlook

Policy changes.--None.

Textile trade changes.--Exports should continue to increase, but a growing share of exports will consist of manmade fiber products.

Cotton's share of fiber use.--Cotton's presently large share will decline rapidly.

#### Raw Cotton Production and Trade

Competitive status and potential production.--Taiwanese cotton production is insignificant, accounting for less than 1 percent of total cotton use. It is unlikely that production will increase before 1980.

Production and trade policy.--There is a low tariff and licensing requirement on raw cotton imports.

Outlook.--No changes.

## OTHER EAST ASIA AND PACIFIC

### Cotton Textile Use and Trade

Status of the textile industry.--This is a textile-importing region. The principal cotton textile producers and consumers are the Philippines and Indonesia. The industries in both countries are based on import substitution. The Philippine industry grew rapidly through the 1950's and slower in the 1960's, while the Indonesian industry began a period of rapid growth in 1965. Cotton is the dominant textile fiber in both countries, but the use of manmade fibers is increasing in the Philippines. The Philippines also has a growing embroidery and apparel industry which processes imported fabrics for reexport.

Trade policies and restrictions.--The domestic markets of both Indonesia and the Philippines are protected. The Philippines has severe restrictions on textile imports and offers various incentives for investment in the textile industry.

### Outlook

Policy changes.--None.

Textile trade changes.--Imports will probably decline to very low levels by 1980.

Cotton's share of fiber use.--Cotton is likely to remain dominant, but its market share will decline more so in the Philippines than in Indonesia.

### Raw Cotton Production and Trade

Competitive status and potential production.--No country or territory in the region grows significant amounts of cotton. In 1969, Indonesia grew about 3,000 bales, or 2 percent of its raw cotton consumption. It is not likely that cotton production will be increased in the region.

Production and trade policy.--Domestic raw cotton needs are supplied by imports. Indonesia buys large quantities of P.L. 480 cotton.

Outlook.--No changes.

Table C-1.--Projections by others of per capita total fiber and cotton use; cotton's share, 1975 and 1980

Region	Per capita total fiber		Cotton's share <sup>1/</sup>		Per capita cotton

## APPENDIX D

### TEXTILE CONSUMPTION AND TRADE STATISTICS, 1964-67

The analysis in this study was based on statistics of textile consumption and trade which were complete for all world regions only through 1964. Data through 1966 or 1967 from FAO or GATT were available only for a limited number of regions. However, since the completion of the study, a new FAO publication, Per Caput Fibre Consumption, 1964-1967 (25), has become available. In addition to supplying more updated statistics on world consumption and trade, this publication has more complete coverage of trade in clothing than previous publications, and includes estimates of the raw fiber equivalent of textile trade.

Although it was not possible to include these new statistical data in the analysis of this study, it was possible to insert them in the historical discussions--which was done. The more inclusive coverage of trade in clothing in the new statistics limits to some extent the comparison between these data and the older data. The lack of comparable pre-1964 data prohibited the use of statistics expressing textile trade in terms of raw fiber equivalent.

Other problems are certain instances where new data do not compare at all with what was previously available, and apparent changes in trends since 1964. These types of problems are apparent in only a few regions, however, and do not seriously affect the conclusions of the study. However, in light of the newly available statistics, the following criticisms of the 1980 projections could be made. The 1980 projections of fiber use and cotton use in Canada, Australia-New Zealand, Republic of South Africa, and East and West Africa may be too low. The regional shares of exports, and thus the amounts of and earnings from exports of cotton textiles projected for 1980 may be too low for Communist Asia and Mexico, and too high for Turkey, India, South Korea, and Hong Kong.

The following tables are a summary of the consumption and trade statistics in Per Caput Fibre Consumption, 1964-1967. Annual figures for 1964-1967 allow some examination of the most recent trends. Trade expressed on a raw fiber equivalent basis is also shown in comparison with trade on an actual weight basis.
