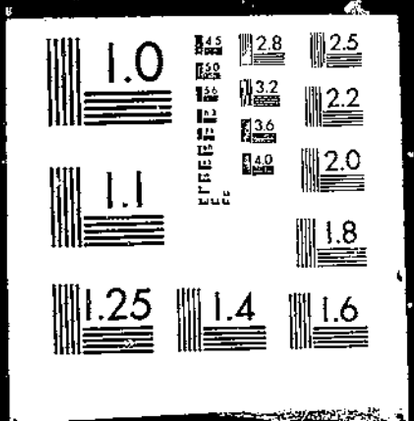
WORLD SUPPLY AND DEMAND PROSPECTS FOR OILSEEDS AND OILSEED PRODUCTS IN 1980 WITH EMPHASIS ON TRADE BY THE LESS DEVELOPED COUNTRIES. (Foreign Agricultural Economic Report). / Lyle E. Moe (and others). Washington, DC: Economic Research Service. Mar. 1971. (NAL Call No. A281.9/Ag8F)



WORLD SUPPLY AND DEMAND PROSPECTS FOR OILSEEDS AND OILSEED PRODUCTS IN 1980

WITH EMPHASIS ON TRADE BY THE LESS DEVELOPED COUNTRIES

FOREIGN AGRICULTURAL ECONOMIC REPORT NO. 71
U.S. DEPARTMENT OF AGRICULTURE • ECONOMIC RESEARCH SERVICE

ABSTRACT

World supply, demand, and trade of oilseeds and oilseed products are projected to 1980 under three alternative projection sets regarding economic development and production growth rates in the less developed countries (LDC's). Focus is centered on world demand prospects for exports of the LDC's. The projections suggest that world trade in oilseed products will continue to be highly competitive. With a continuation of recent supply and demand trends and policies, world prices for vegetable oils would decline and prices for oilcakes would remain stable. If LDC's increased their exportable supplies, world prices of both vegetable oil and oilcakes would decline, net earnings of LDC's from oilcakes would greatly increase, but combined net trade earnings from oilseed products would decrease.

World import markets for oilcakes will continue to be found almost exclusively in developed countries. Increased production in many LDC's would be absorbed by internal demand. Import demand for vegetable oils will become much greater in the LDC's. Per capita nutritional levels will improve in LDC's. There is an implied need for continued concessional sales of vegetable oil to importing LDC's. LDC's include both importing and exporting countries, making it difficult for them to achieve among themselves a consensus on policy objectives. Lower world prices for oilseed products would benefit importing countries but would adversely affect earnings of exporting countries.

Key words: Oilseeds, vegetable oil, oilcake, world supply and demand, projections, foreign trade.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C., 20402

FOREWORD

Oilseeds and their products are some of the primary agricultural commodities traded on the world market. Not only is the volume of trade large, but also it grew substantially in the decade of the sixties. Further growth is expected due to rising levels of income and population growth.

This analysis focuses upon the expected long-term demand for oilseeds and their derivatives, especially from the perspective of potential exports of less developed countries (LDC's). Due to the independence of vegetable oil and oilseed meal markets, separate demand estimates are made under three sets of assumptions. Under these, the net trade earnings of LDC's are projected to be at lower levels in 1980 than they were in the 1963-65 base period.

Attention is called to several of the conclusions of the analysis. World trade is expected to continue to be highly competitive. Prices of vegetable oils will most likely decline and those of oilmeal remain relatively stable. The import demand for vegetable oils in LDC's and for oilmeal in developed countries will experience the greatest expansion. Increases in production will meet increased internal demand in many LDC's, several of which are importers of these commodities.

This study was part of a research project on "Demand Prospects for Agricultural Products of Less Developed Countries" conducted by the Economic Research Service under a participating agency service agreement for the Agency for International Development.

The research on demand prospects for agricultural products of less developed countries was conducted under the direction of an ERS Technical Advisory Committee, with Louis F. Herrmann as Chairman. Arthur B. Mackie and Anthony S. Rojko served as advisors and research leaders.

ACKNOWLEDGMENTS

The oilcake demand projections for the developed countries, contained in chapter 10, were developed by Donn A. Reimund, Marketing Economics Division (MED), Economic Research Service (ERS). Arthur Coffing, Foreign Regional Analysis Division (FRAD), ERS, contributed to the preparation of chapters 7, 8, and 9. Pauline Price and Lillian Loeb (both of FRAD) and Barbara Johnson and Nina Swann (both of MED) assisted in compiling statistical data for this report.

SUMMARY

With rising levels of population and income, world production and trade of oilseeds and oilseed products are expected to continue to grow. World supply and demand projections show that by 1980, the level of vegetable oil demand will increase substantially over the 1963-65 level, with over half the expansion among the less developed countries (LDC's). Oilcake demand will also increase over 1963-65 levels, with developed countries making the greatest use of the commodity. World trade in oilseed products will continue to be highly competitive.

Projections of production, consumption, trade, and prices in this report vary according to alternative assumptions about trade policies, agricultural productivity, and economic growth.

With constant 1963-65 prices, a continuation of present trends and policies, and moderate gains in productivity in the LDC's (projection set I), 1980 world supply and demand for oilcakes would be in balance. However, under set I, the vegetable oil price would need to drop by about 20 percent to bring world demand in line with supply. Because oilcakes are principally used as a protein supplement to livestock feed, an increase in import demand would occur primarily in developed countries, where there is a high effective demand for animal products.

Projected earnings from vegetable oil by exporting LDC's would increase moderately over the 1963-65 level, while costs to importing LDC's would increase substantially because of rapid projected increases of vegetable oil imports by these countries. Net earnings of the LDC's from vegetable oil exports would be substantially below the level of net earnings during the mid-1960's. On the other hand, total LDC earnings from oilcakes would increase by 1980. Combined net trade earnings of the LDC's from vegetable oil and oilcakes, however, would be lower in 1980 than they were in 1963-65.

Projection set II assumes a higher level of economic growth and agricultural productivity in the LDC's. Their annual growth rate in oilseed production is assumed to be 40 percent higher than under set I. To bring world demand in line with the increased production, a 31-percent decline in vegetable oil prices and a 13-percent decline in oilcake prices are projected from the 1963-65 price levels. With higher income levels in the LDC's, their demand for vegetable oil would increase considerably. As a result, vegetable oil import costs would rise above and export earnings would drop below those of set I. LDC export earnings from oilcakes, however, would greatly increase. Consequently, LDC net export earnings from oilseed products would be greater under set II than under set I, but still lower than the 1963-65 level.

Projection set III assumes a lower level of economic growth and agricultural productivity in the LDC's. Their oilseed production is assumed to drop 30 percent below that projected under set I. With a decline in production and income, vegetable oil prices would drop 13 percent below the 1963-65 level, and oilcake prices would increase 8 percent. Net LDC export earnings would be less under set III than under the two other alternatives--mainly because of the lower level of trade--and such earnings would also be below the 1963-65 level.

Given the projected world supply and demand conditions for vegetable oils and oilcakes, the following conclusions are evident:

.... Per capita nutritional levels will improve.

.... There is an implied need for continued concessional sales of vegetable oil to less developed importing countries.

.... LDC's include both importing and exporting countries, making it difficult for them to achieve among themselves a consensus on policy objectives. Lower world prices for oilseed products would benefit importers but would adversely affect earnings of exporting countries.

.... With a continuation of present supply and demand trends and policies, world prices for vegetable oils would decline and prices for oilcakes would remain stable.

.... With higher production levels in the LDC's, their efforts to increase exportable supplies would result in reducing world prices of both vegetable oil and oilcakes, but net export earnings by the LDC's would increase as a result of increased earnings from oilcakes.

.... Increased domestic production in many LDC's would be absorbed by internal demand.

.... World import demand for vegetable oils will become much greater in the LDC's.

.... World import markets for oilcakes will continue to be found almost exclusively in the developed countries.

WORLD SUPPLY AND DEMAND PROSPECTS FOR OILSEEDS AND OILSEED PRODUCTS IN 1980
With Emphasis on Trade by the Less Developed Countries

Foreign Regional Analysis Division, Economic Research Service

PART I.--INTRODUCTION AND REVIEW OF PRICES

1.--INTRODUCTION

The specific objective of this study is to estimate long-term prospects for world trade in oilseeds and oilseed products.

Analysis is primarily directed to demand and, to a lesser degree, supply. For the less developed countries (LDC's), this report indicates the probable magnitude of foreign exchange expenditures for and earnings from oilseeds and oilseed products.

Most oilseeds yield both vegetable oil and oilseed meal in relatively fixed proportions. Markets for the two products are largely independent and the growth rates of demand for oil and for meal can vary sharply. The complexity of the demand for oilseeds is indicated in figure 1, a flow chart of the French fats and oils economy during 1958-60.

Part II of this report concentrates on demand for vegetable oil and part III primarily concerns demand for oilseed meals. Part IV "marries" the two analyses, develops production projections, and presents the resulting trade implications.

The projections in this study are neither targets to be aimed at nor forecasts of what will actually take place. Rather, they are estimates, based on specific assumptions, of probable future demand for and supply of oilseeds and oilseed products. The assumptions used are meant, of course, to be as realistic as possible, and recent past experience is their point of departure. Therefore, the projections supply the basis for their own amendment in the future, should the underlying assumptions be changed as a result of new information or new policies. In some instances, enough statistical data have not been available to permit analysis of various economic relationships. Also, the reliability of the available data is not always as high as may be preferred. Finding enough reliable data is especially difficult for oilseeds because of the large number of crops involved.

Basic Definitions 1/

Key terms used in this report are defined as follows:

Oilseeds

Unless otherwise indicated, "oilseeds" include soybeans, peanuts, cottonseed, sunflowerseed, rapeseed, copra, and palm kernels. Since linseed oil is classified as an industrial oil, flaxseed is not included in this study's analysis of vegetable oil demand. However, in the analysis of oilcake demand, flaxseed is included.

Vegetable Oils

Unless otherwise indicated, "vegetable oils" include soybean oil, peanut oil, cottonseed oil, sunflowerseed oil, rapeseed oil, coconut oil, palm kernel oil, palm oil, and olive oil.

Oilcakes

The term "oilcakes" is applicable to both expeller cake (obtained from pressing seeds and generally containing 3-7 percent oil by weight) and extracted meals (obtained from solvent extraction of seeds and generally containing less than 1 percent oil by weight). The terms "oilcakes" and "meal" are therefore synonymous in this report.

Unless otherwise indicated, "oilcakes" include the meal and cake from soybeans, peanuts, cottonseed, sunflowerseed, rapeseed, copra, palm kernels, and linseed.

Oil-Equivalent Basis

The quantity of oil contained in oilseeds produced and in oilseeds traded is converted to an oil-equivalent basis. For example, to obtain a total oil trade figure for a region, the quantity of vegetable oil shipped in the form of oilseeds, or oil-equivalent, is added to the quantity of vegetable oil traded as such.

Meal-Equivalent Basis

The quantity of meal contained in oilseeds produced and in oilseeds traded is converted to a meal-equivalent basis. For example, to obtain a total meal trade figure for a region, the quantity of meal shipped in the form of oilseeds, or meal-equivalent, is added to the quantity of meal traded as meal.

Units of Measurement

Metric tons are used unless otherwise noted.

Time Reference

Trade, production, and consumption are on a calendar year basis.

1/ A more detailed discussion of oilseeds and oilseed products and their uses appears in app. C, pp. 191-200.

Regional Grouping

For vegetable oils, the world is divided into 18 regions, based on economic, political, and geographic criteria.

Developed

1. United States
2. Canada
3. European Community ..... Belgium-Luxembourg, France, Federal Republic of Germany, Italy, and the Netherlands.
4. United Kingdom
5. Other Western Europe ..... Austria, Denmark, Finland, Greece, Iceland, Ireland, Malta, Norway, Portugal, Spain, Sweden, and Switzerland.
6. Japan
7. Australia and New Zealand
8. Republic of South Africa

Central Plan

9. Eastern Europe ..... Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Romania, and Yugoslavia.
10. USSR
11. Communist Asia ..... Mainland China, Mongolia, North Korea, and North Vietnam.

Less Developed

12. Central America and Mexico ..... British Honduras; Carribbean including Cuba, Costa Rica, El Salvador, Guatemala, Honduras, Mexico, Nicaragua, and Panama.
13. South America ..... Argentina, Bolivia, Brazil, French Guiana, Paraguay, Surinam, Uruguay, Venezuela, Chile, Colombia, Ecuador, Peru, and Guyana.
14. East and West Africa ..... Botswana, Burundi, Ethiopia, Kenya, Lesotho, Malagasy Republic, Malawi, Mauritius, Mozambique, Rhodesia, Rwanda, Somalia, Swaziland, Tanzania, Uganda, and Zambia.

    Angola, Cameroon, Central African Republic, Chad, Congo (Kinshasa), Congo (Braz.), Dahomey, Gabon, Gambia, Ghana, Guinea, Ivory Coast, Liberia, Mali, Mauritania, Niger, Nigeria, Portuguese Guinea, Senegal, Sierra Leone, Togo, Upper Volta and Other Portuguese West Africa.
15. North Africa and West Asia ..... Algeria, U.A.R. (Egypt), Libya, Morocco, Sudan, Tunisia, Bahrein, Cyprus, Iran, Iraq, Israel, Jordan, Kuwait, Lebanon, Muscat and

		Oman, Qatar, Saudi Arabia, South Yemen, Syria, Trucial States, Turkey, and Yemen.
16.	South Asia	Afghanistan, Bhutan, Ceylon, India, Nepal, and Pakistan.
17.	Southeast Asia	Burma, Cambodia, Laos, South Vietnam, and Thailand.
18.	East Asia and Pacific Islands	Brunei, China (Taiwan), Hong Kong, Indonesia, South Korea, Macao, Malaysia, New Guinea, Pacific Islands, Papua, Philippines, and Singapore.

For oilcakes, the world is divided into 13 rather than 18 regions--nine regions used in the vegetable oil analysis were combined into four regions for the oilcake analysis:

Republic of South Africa
Australia and New Zealand

South America
Central America and Mexico

East and West Africa
North Africa and West Asia

South Asia
Southeast Asia
East Asia and Pacific Islands

2.--EXPORT EARNINGS, IMPORT COSTS, AND PRICES OF OILSEEDS AND OILSEED PRODUCTS

Export Earnings or Import Costs

World export earnings from the oilseeds and oilseed products of primary concern to this report averaged some $2,901 million during 1963-66. Trade in oilseeds was valued at $1,458 million; trade in vegetable oil amounted to $898 million and trade in oilseed meals, to $545 million (table 1).

The less developed countries earned an average of $1,344 million in foreign exchange from oilseeds and their products during 1963-66. Imports for the LDC's averaged $421 million. Thus, net exports were $923 million. LDC's exported $268 million worth of oilseed meals, while imports averaged only $7 million. Their vegetable oil exports were $440 million, while imports were $269 million to bring about net exports of $171 million. LDC's exports of oilseeds, as such, averaged $636 million; imports amounted to $145 million.

Developed countries provide the bulk of the market for oilseed exports of the LDC's. During 1963-66, the developed countries' imports of oilseeds and oilseed products averaged $2,405 million a year. This is approximately 80 percent of total world imports.

By region, average annual net export earnings from oilseeds and oilseed products during 1963-66 were greatest for the United States--$864 million. Such net exports provided the East and West Africa region with $473 million a year, while the East Asia and Pacific Islands region earned $341 million. Trading pattern differences within regions are, naturally, reflected in export earnings. For instance, South America was a net importer of oilseeds and vegetable oils but a net exporter of meals, so on balance the region was a net exporter.

For the European Community (EC), net imports of oilseeds and oilseed products during 1963-66 averaged some $993 million. The United Kingdom's net imports averaged $292 million, while Japan's averaged $283 million. Net imports of the Other Western Europe (O.W.E.) region amounted to $327 million. Individual regional trade in oilseeds and oilseed products for 1963-66 is presented in appendix A.

On a commodity basis, the largest export earner among the oilseeds in 1966 was soybeans, $859 million, followed by peanuts, $295 million, and copra, $245 million (table 2). The major vegetable oils traded in 1966 were sunflowerseed oil, $175 million, and soybean oil, $160 million, followed by peanut oil, coconut oil, and palm oil, which were all around $143 million. Palm kernel oil was the least important--$28 million.

By value, soybean meal was the most important meal exported in 1966. Soybean meal exports, which totaled $297 million, were followed by peanut meal, $129 million, and cottonseed meal, $71 million.

Prices

The profitability of trade is primarily determined by the level of prices received. The price of copra, palm kernels, and peanuts has consistently been well above the price of soybeans, while rapeseed, sunflowerseed, and cottonseed prices have been relatively close to the soybean price, especially in recent years (table 3).

The price levels of oilseeds are determined by the price of their oil and meal components. The combined value of the meal and the oil is greater than the price per ton of the parent product since oil and meal values include, among other things, crushing costs and margins. Among the oilseed products, the value of soybean meal is greater than the value of soybean oil per ton of the product. The price for copra, palm kernels, rapeseed, and flaxseed is determined mainly by the value of the oil contained in each. The value of peanut oil has been two to three times as great as the value of peanut meal. The oil value in sunflowerseeds has been about twice as large as the meal value, while for cottonseed, the meal and oil values have been relatively equal.

During 1955-68, the value of soybeans, copra, and palm kernels generally increased, while the value of peanuts, sunflowerseed, cottonseed, rapeseed, and flaxseed declined. During the same period, the oil component value declined for all of the oilseeds except copra and palm kernels. Conversely, the value of the meal has been increasing for all commodities except sunflowerseed.

The main component determining the price of the parent product strongly influences the future price prospects of an oilseed product. For example, soybean meal constitutes the bulk of soybean value and while soybean oil prices have been declining, meal prices have been increasing. As a consequence, the price for soybeans has been relatively firm. For peanuts, the price of meal has also been increasing, while the price of peanut oil has been trending down. Since the major portion of the value of peanuts is in the oil, peanut prices have been declining.

Vegetable Oil Prices

The price levels that bring supply and demand into equilibrium on the world market represent the total effect of decisions taken by a large number of individuals, companies, and organizations that make up the fats and oils market. International market prices of fats and oils move freely in response to changes in supply and demand within this highly complex market. To date, they have operated satisfactorily in providing a flexible process for bringing supply and demand into equilibrium, although at declining prices.

Price developments of individual oilseeds and vegetable oils cannot be explained primarily by changes in supply and demand on the markets of the individual commodities. Short-term fluctuations in prices result largely from changes in the supply of each individual oilseed commodity and in the prices of substitutable oils and fats. Prices are also determined by changes in supplies from domestic production in the main importing countries as well as price changes on the world market. Also, price changes for oilseeds may differ significantly from price changes for vegetable oils--for reasons that have to do with the policies of crushers, the policies of the governments of importing and exporting countries, and the demand for byproducts (cakes and meals) (26, p. 55). 2/

Technical and economic factors influence the substitutability of fats and oils. From the technical point of view, most individual fats and oils are interchangeable

2/ Underscored numbers in parentheses refer to references listed at the end of this report.

since the various characteristics of the oils can be altered by processing. As indicated in appendix C, soft oils can be hardened and flavors can be added, moderated, or entirely removed, for example. All of the soft oils used for cooking or for salad oils are substantially interchangeable and additionally, butter, lard, and the palm oils are used as cooking fats. For the manufacture of margarine and shortening, all the soft oils, palm oils, and lard are substitutable to a large degree.

The chief economic factors influencing interchangeability, apart from consumer preferences, are the availability of different kinds of fats and oils and, where substitution is not too difficult, their relative prices. The possibility of storing oilseeds, oils and fats, and their products enhances the scope for interchangeability (15, p. 7).

The utilization of any individual oil cannot be considered without reference to the end use in which it is incorporated because the margin on different products can vary widely. For some products, a small increase in price in any individual oil might mean its elimination from usage because of the close degree of substitutability of a cheaper oil. On the other hand, to obtain a premium product, the continued use of the specific oil might be considered worthwhile despite the price increase. Thus, it is difficult to indicate with any degree of accuracy how wide the margin must be between the various oils and fats to encourage a greater use of one over another.

Advances in technology have made it possible to use a wider variety of oils and fats as substitutes. Changes in the composition of margarine in recent years are an example. A study of the changing composition of margarine in a group of Western European countries during 1958-63 indicated substantial increases in use of marine oils, animal fats, and soybean oil (20). By contrast, there were decreases in use of lauric oils (coconut and palm kernel), palm oil, and peanut oil. Once technology comes into play, prices are more significant in determining the use of various vegetable oils.

Increasing interchangeability among fats and oils has had two discernible effects on their prices over time: (a) The scatter or spread of prices of the various kinds has become narrower over a long period because the increasing scope for substituting cheaper for more expensive kinds tends to raise the long-term price level of the former and lower the price level of the latter, in relative terms; and (b) over a long period, short-term divergences in prices of one kind of fat or oil from their own trend or from the general average of many kinds become smaller and briefer since users of an oil that temporarily becomes unusually expensive can more easily and quickly substitute an oil whose price has not risen or has not risen as much.

The degree to which the prices of different vegetable oils have moved together is a good indication of their substitutability. Such movements can conveniently be expressed in terms of correlation coefficients. In a recent report (13), a matrix of price correlation coefficients was calculated for four soft oils and the two lauric oils (coconut and palm kernel), covering data for 1950-66. To complete the matrix for the vegetable oils under consideration in the present report, correlation coefficients were computed for the remaining oils for the same time period. A summary of the results is given in table 4.

These calculations clearly show that while the prices of the two lauric oils are very closely related, they bear no significant relationship to the prices of any of the other seven oils. This is not surprising in view of the distinct qualitites of the lauric oils (see app. C).

Olive oil prices also displayed a low correlation with other vegetable oil prices. This was probably due in part to the sharp variations in annual production of olive oil and in part to the distinct demand for the oil, especially in the Mediterranean countries, despite its high price level.

Among the soft oils and palm oil, there is a network of close price relationships. This close linkage is as expected in view of the high degree of substitutability of these oils.

Price Flexibilities

This section measures the factors affecting the level of international prices for selected vegetable oils. To permit comparisons of the price responsiveness of these oils, price flexibilities were computed. Price flexibility is defined as the percentage change in the price of a commodity associated with a 1-percent change in the quantity produced of that commodity or a related variable, all else remaining constant. 3/

In the development of price flexibilities, the two lauric oils are considered by themselves because of their low price correlation with the prices of the other oils. For similar reasons, olive oil is considered by itself. The remaining six oils are grouped together and are called "other oils" for the purposes of this section.

Multiple regression analysis is used with the international market price as the dependent variable. Quantities produced in the current year, quantities produced in the previous year, and income are the independent variables. A lagged production variable was introduced because of the absence of stock data. When the data are expressed in logarithms, the regression coefficients can be viewed as price flexibility estimates.

Several regressions were developed with 1955-68 data, for the lauric oils, olive oil, and the other oils. The following regressions were selected on the basis of confirmation of the estimated coefficients to a priori knowledge derived from economic theory and on the basis of their "t," "F," and "R^2" values:

(a) Lauric oils:

$$\underset{}{\text{Log } P^l_t} = 5.46 - \underset{(1.99)}{2.357}\ \text{Log } Q^l_t + \underset{(0.91)}{1,145}\ \text{Log } Q^l_{t-i} + \underset{(1.20)}{0.616}\ \text{Log } I_t$$

$F = 4.0$ $\qquad R^2 = .43$

(b) Olive oil:

$$\underset{}{\text{Log } P^o_t} = 5.477 - \underset{(4.60)}{0.821}\ \text{Log } Q^o_t - \underset{(1.74)}{0.314}\ \text{Log } Q^o_{t-1} + \underset{(1.75)}{0.395}\ \text{Log } I_t$$

$F = 7.4$ $\qquad R^2 = .71$

(c) Other oils:

$$\underset{}{\text{Log } P^{oo}_t} = 4.607 - \underset{(2.51)}{0.511}\ \text{Log } Q^{oo}_t$$

$F = 6.3$ $\qquad R^2 = .36$

3/ Price flexibilities are discussed in (30, pp. 53-55).

where:

P_t^l = weighted[4] international price of coconut oil and palm kernel oil

Q_t^l = current quantity of world lauric oils production

Q_{t-1}^l = lagged quantity of world lauric oils production

I_t = national product index of developed countries

P_t^o = international price of olive oil

Q_t^o = current quantity of world olive oil production

Q_{t-1}^o = lagged quantity of world olive oil production

P_t^{oo} = weighted[4] international price of the six other vegetable oils

Q_t^{oo} = current quantity of other vegetable oils produced, world basis

The estimated "t" values appear in parentheses below the estimated coefficients.

The estimated price flexibility of lauric oils indicates that a 1.0-percent change in the quantity produced would be associated with about a 2.4-percent change in the price in the opposite direction, other things remaining equal. This means that opposite price movements more than offset the effect of quantity changes. In sharp contrast, the estimated price flexibility for olive oil indicates about a 0.8-percent price decline with a 1.0-percent production increase. 5/ For the other oils, the estimated price flexibility indicates that during 1955-68, the price declined about 0.5 percent with each 1.0-percent quantity increase.

The reciprocal of the price flexibility estimate may be considered as an approximation of the price elasticity of demand (30). Based on the price flexibilities, the implied price elasticities of demand were computed to be -0.4 for lauric oils, -1.2 for olive oil, and -2.0 for the other oils. In view of the inelastic price elasticity for lauric oils, one would, of course, expect a change in price greater than the rate of change in production. The converse would be true for olive oil and the other oils.

Effects of U.S. Public Law 480 on World Prices

The effect on world prices of large-scale P.L. 480 concessional shipments of vegetable oil is important in view of the high degree of substitutability among vegetable oils.

Soybean and cottonseed oils are the major oils under the provisions of P.L. 480. Soybean oil shipments are the most important; in 1965, they totaled some 350,000 tons.

A recent study of the world soybean market included an analysis of the impact on the market of P.L. 480 exports of soybean oil (31). The study concluded that "concessional exports of soybean oil under P.L. 480 have done much to sustain prices and incomes of growers in the soybean sector since the mid-fifties and the abandonment of these shipments in 1965 would have depressed oil prices an estimated 2 or 3 cents per pound, and bean prices by as much as 28 cents per bushel." Reworded, P.L. 480 shipments of soybean oil in 1965 increased the price of soybean oil on the normal U.S. commercial market by about 20 percent above what it would have been in the absence of such shipments. The United Nations Food and Agriculture Organization (FAO) has stated that since

4/ Weighted by the volume of world trade of each oil (table 2) and the international price of each oil (table 3).

5/ Dr. Al-Zand, using 1950-66 data, obtained a price flexibility of -0.835 for olive oil (2, p. 126).

soybean oil is the major vegetable oil traded in the world, it seems reasonable to assume that the market prices of other oils, particularly those most interchangeable with soybean oil, were higher than they would have been had the P.L. 480 vegetable oil shipments been placed on the commercial market (19, p. 5).

Oilcake Prices

International prices for oilcakes have trended upward in the past decade as a result of a sustained increase in demand. The increase in demand has been primarily due to an increase in livestock production and the feeding of more concentrate rations per unit of livestock output. The increased production of animal products has occurred mainly because of increases in per capita income and population and changes in dietary habits in many economically advanced countries of the world.

With respect to demand for different types of oilcakes, substitutability does exist in varying degrees even though chemical and biological characteristics of the oilcakes differ (see app. C). A study of the structure of the soybean export market states:

> Individual high-protein feeds, for example soybean meal and linseed meal, are substitutable in varying degrees in mixed feeds with other high-protein feeds such as the meals of peanut, cottonseed, copra, fishmeal, alfalfa, meat scraps, and tankage.
>
> The practicality of such substitution depends on a number of factors, including relative prices, growth rate for the consuming animal, and ability of the meals to meet their amino-acid requirements. As a consequence of such substitution, the elasticity of demand for any given high-protein feed may be expected to be greater than the elasticity of demand for high-protein feeds in the aggregate (4, pp. 19-20).

The degree to which prices of the different oilcakes have moved together, as expressed in terms of correlation coefficients, was used to measure the substitutability of different oilcakes (table 5). Data for prices of six oilseed meals and fishmeal for 1955-66 are given in table 3.

As expected, the calculations indicate that prices of the various oilcakes are closely related. The varying degrees of price correlation among the various oilcakes, apart from supply constraints, are partly due to differences in the crude protein content and to differences in the essential amino-acid composition of such protein. For example, sunflowerseed meal contains about 28 percent protein, while soybean meal is nearly 46 percent crude protein. Soybean meal and peanut meal are nearly identical with respect to crude protein content, but soybean meal is preferable--mainly because its lysine content, one of the more restricting essential amino-acids, is about 65 percent greater than that of peanut meal. The essential amino-acid pattern of protein in various meals is contained in appendix table C-1.

Price Flexibilities

As with vegetable oils, price flexibilities for oilcakes were computed to estimate price responsiveness to changes in supply. Because there were no sharp disparities in the price correlation coefficients of the different oilcakes, price flexibility estimates were developed with 1955-66 data for all meals combined. The following three regressions were developed:

$$\text{(a)}\quad \text{Log } P = 1.354 - \underset{(0.64)}{0.391}\ \text{Log } Q_{mt} - \underset{(1.21)}{0.578}\ \text{Log } Q_{mt-1}$$

$$+ 1.465 \underset{(2.58)}{\text{ Log I}}$$

$F = 13.4 \qquad R^2 = .83$

(b) $\text{Log P} = .702 - \underset{(0.96)}{0.579 \text{ Log } Q_{mt}} + \underset{(2.23)}{1.120 \text{ Log I}}$

$F = 18.4 \qquad R^2 = .80$

(c) $\text{Log P} = 1.062 - \underset{(0.23)}{0.142 \text{ Log } Q_{mt}} - \underset{(1.60)}{0.522 \text{ Log } Q_{gr}}$

$$+ \underset{(2.25)}{1.051 \text{ Log I}}$$

$F = 15.2 \qquad R^2 = .85$

where:

P = international prices of peanut, coconut, palm kernel, soybean, cottonseed, linseed, sunflower, and rapeseed meals. The prices are weighted by the volume of world trade of each meal

Q_{mt} = current quantity of world oilcake production

Q_{mt-1} = lagged quantity of world oilcake production

I = national product index of developed countries 6/

Q_{gr} = current quantity of world corn, barley, and oats production

The estimated "t" values appear in parentheses below the estimated coefficients.

In equation (a), world production and lagged world production of oilcakes were not good explanatory variables, but the income variable was significant. This is not surprising because sharp increases in demand absorbed production increases during 1955-66. The estimated price flexibility indicates that a 1.0-percent change in production would be associated with an approximate .4-percent change in the price of oilcakes in the opposite direction, other things remaining equal.

Equation (b) is the same as equation (a) with the exception of lagged production. The lag variable was deleted to see if the production variable would show any statistical significance. The "t" value for the production coefficient increased but it still was not a good explanatory variable.

In equation (c), world grain production was added as an independent variable to measure its significance on meal prices. World production of grain was significant at the 10-percent level. The equation indicates that a 1-percent increase in world grain production would reduce world meal prices by 0.5 percent, other things remaining equal. The equation also indicates that on the world level, oilcakes and grain are substitutes. However, within certain price limits, the two tend to be complementary rather than substitutes in the compound feed industry. As technological advances are continued in the mixed-feed industry, the tendency to substitute is likely to increase.

6/ Index constructed from Moe's population study (44).

Oilseeds

Peanuts: Nigerian, shelled.
Cottonseed: Sudanese, bulk.
Soybeans: U.S. No. 2 yellow.
Sunflowerseed: East African, pure.
Rapeseed: Canadian, 40 percent bulk.
Copra: Straits.
Palm kernels: Nigerian.
Flaxseed: Canadian, No. 1, 2 1/2 percent bulk, c.i.f. U.K.

Oils and Fats

Peanut oil: Nigerian 3-6 percent bulk.
Cottonseed oil: American, crude, bulk.
Soybeans: Any origin, crude.
Sunflower oil: Argentine, semi-refined, bulk.
Rapeseed oil: Any origin, ex-tank Rotterdam.
Coconut oil: White Ceylon, 1 percent bulk.
Palm kernel oil: Net, naked, ex-mill London.
Olive oil: Spanish, edible, 1 percent drums, f.o.b.
Palm oil: Nigerian, 5 percent c.i.f., U.K.
Butter: New Zealand finest, ex-store, London.
Lard: U.K., American, bulk.

Oils and Fats con't.

Fish oil: Peruvian, semi-refined.
Whale oil: Crude
Linseed oil: Argentine-Uruguayan, c.i.f. U.K.

Oilseed Meals:

Peanut meal: Nigerian, 56 percent.
Cottonseed meal: Argentine, 44/45 percent.
Soybean meal: Canadian, 45 percent.
Sunflowerseed meal: Argentine. 37/38 percent.
Copra meal: Indian, 30 percent.
Linseed meal: Argentine, 37/38 percent.
Fish meal: Peruvian, 65 percent

2/ Nigerian.
3/ Estimated.
4/ Malayan, 5-percent bulk.

PART II.--WORLD DEMAND FOR VEGETABLE OILS

Since this report concentrates on oils of primary importance to the less developed countries from an export-earning point of view, demand projections are not developed for the animal fats and the marine oils. The animal fats--such as butter, lard, and tallow--are the byproducts of milk and meat production. The marine oils--fish and whale oils--are the byproducts of the fishing industry. Thus, besides being of limited importance from a trade point of view to the LDC's, production of animal fats and marine oils is not closely related to demand for fats and oils, but to supply and demand for the main products from which they are derived.

Vegetable oils are often subdivided into three broad groups according to their consistency in temperate climates: (1) "Soft" oils consist principally of soybean, peanut, cottonseed, rapeseed, sunflowerseed, and olive oils, which are used mainly for human consumption, largely in direct liquid form, but also in the manufacture of margarine and shortening; (2) "hard" oils consist of products of palm trees--coconut, palm kernel, and palm oil--which are used both for food, mainly in margarine manufacturing and baking, and for industrial purposes, mainly in soap; and (3) "industrial" or "technical" oils consist mainly of linseed, tung, and castor oils, which are principally used as lubricants and as drying agents in products such as paints and varnishes.

The vegetable oils to which this report gives primary consideration are: soybean, peanut, cottonseed, sunflowerseed, rapeseed, olive, coconut, palm kernel, and palm oil. Excluded are edible vegetable oils of minor importance from a trade point of view, such as corn, safflower, sesame, and babassu kernel oil. Also excluded are the industrial oils, which are of minor importance from a trade point of view to the LDC's and which have a demand schedule that is sharply different from the demand schedule for the edible vegetable oils.

3.--INTERNATIONAL TRADE IN VEGETABLE OIL

Level of Trade

World exports of vegetable oils increased 4.5 percent annually from 1955-57 through 1963-65 (table 6). 1/ A striking feature in the development of vegetable oil exports during the period was the difference in the rate of increase of the developed countries' exports compared with that of the other countries. The developed countries increased their exports 7.3 percent a year, while the central plan countries increased exports at 3.7 percent and the LDC's at 3.1 percent.

During 1955-57 through 1963-65, there were also marked differences in the composition of the exports among the regions. The annual rate of increase in exports of oil in the form of oilseeds was 13.3 percent for the developed countries, but only 2.9 percent for the LDC's. In the central plan countries, such oil-equivalent exports declined at an annual rate of 6.5 percent. Conversely, exports of vegetable oil as such increased more than 24 percent a year in the central plan countries, but only 3.9 percent in the LDC's and 2.9 percent in the developed countries.

On a world basis, the developed countries' share of world exports increased from 20 to 36 percent from 1955-57 through 1963-65. The central plan countries' share declined from 13 to 5 percent of the total, while the less developed countries' share dropped from 67 to 59 percent.

The developed countries took some 74 percent of the world's total vegetable oil imports in 1963-65--a decline from 80 percent during 1955-57. This was due to a relative decline in the imports of vegetable oil as such--from 81 to 65 percent of the world's total. The central plan countries' share of total vegetable oil imports increased from 5.6 to 6.5 percent. The LDC's, however, increased their share from 14 to 19 percent.

The total import and export trade of each of the 18 regions was developed from 1955 to as far forward as data permitted. For all of the developed regions, trade data were available through 1967. For most of the LDC's and central plan countries, trade data were available only through 1965. Thus, the time span for considering the trade of all regions is 1955-65.

Relative Importance of Trading Regions

Exporting Regions

The position of the exporting regions changed considerably from the 1950's to the 1960's. During 1955-57, the East Asia and Pacific Islands region was the leading exporter; the East and West Africa region, second; the United States, third; and Communist Asia and South Asia, fourth and fifth, respectively. In 1963-65, the United States was the largest exporting region, followed by East Asia and the Pacific Islands, East and West Africa, the EC, and the USSR, respectively. On a net export basis, the East and West Africa region was the largest, while East Asia and the Pacific Islands ranked second and the United States, third. These three regions dominated the world market in the same order of importance in both periods. Communist Asia shifted from the fourth-ranked net exporter in 1955-57 to the fifth-ranked in the 1960's. The

1/ World exports are the total of oil traded in the form of oil plus the oil equivalent of oil traded in the form of oilseeds.

USSR, which was a net importer during 1955-57, was the fourth leading net exporter by 1963-65. Conversely, South Asia, the fifth leading net exporter in 1955-57, was a net importer during 1963-65.

Importing Regions

The most significant importing region in 1955-57 was the EC, followed by the United Kingdom, Other Western Europe, the United States, and Japan. In 1963-65, the EC was still the leading importer, but O.W.E. was the next most important market, followed by the United Kingdom, North Africa and West Asia, and Japan. On a net importer basis, the regions rank somewhat differently. In 1955-57, the EC was the world's leading market, followed by the United Kingdom, O.W.E., and Japan. The same order of importance was maintained in 1963-65. The North Africa and West Asia region, which was a net exporter in 1955-57, replaced the USSR in the 1960's as the fifth largest net import market.

Changes in Trade Levels

Net Exporting Regions

The United States accounts for approximately three-fourths of the vegetable oil exports originating from the developed countries. During 1955-57 through 1963-65, total U. S. vegetable oil exports increased 8.1 percent a year. U. S. oilseed exports on an oil-equivalent basis increased at 13.2 percent a year, while exports of oil as such increased only 2.8 percent a year. This disparity, of course, is a reflection of the rapid expansion of soybean exports from the United States.

Among the central plan countries, the USSR phenomenally changed its position from a net importer during the mid-1950's to a net exporter in the mid-1960's. The shift in the USSR's trade position has had very widespread effects on the world vegetable oil market in recent years. Although the average volume of exports in 1963-65--243,600 tons--was not relatively significant in the world total, exports by 1967 had risen to 707,000 tons. The bulk of these exports has been sunflowerseed oil. Traditionally, the East European countries have absorbed most USSR sunflowerseed oil exports. In recent years, however, Russia has had to look increasingly elsewhere to market its large volume of oil.

Communist Asia was a relatively large exporter of vegetable oil during 1955-57. However, through 1963-65, exports declined at an average annual rate of 12.2 percent. The decline was primarily due to reduced production, mainly of soybeans, in Mainland China.

With respect to exporters in the less developed regions, the East and West Africa region continued to maintain its position as a major exporter. During 1955-57 through 1963-65, exports expanded at an average annual rate of 3.4 percent. This increase was primarily due to increases in peanut production. Exports of the other major oil from the region, palm oil, declined slightly.

In the East Asia and Pacific Islands region, exports increased at an annual rate of 2.3 percent between 1955-57 and 1963-65. Oil palm production in this region has increased markedly since 1965 and, consequently, the region currently has a much larger role in the world vegetable oil market than it did in 1963-65.

Net Importing Regions

The EC is easily the world's leading market for vegetable oils. While its net imports of vegetable oil as such increased only 1.3 percent annually from the mid-1950's to the mid-1960's, imports on an oil-equivalent basis increased nearly 3.0 percent. The EC's demand for high-protein oilseed meals has risen sharply since the mid-1950's, and one of the side consequences has been the rise in vegetable oil imports on an oil-equivalent basis.

The United Kingdom relies almost wholly on imports to meet its vegetable oil needs. Its net imports of vegetable oils declined in excess of 2.0 percent a year from the 1950's through the mid-1960's. Offsetting this decline were large increases in imports of butter, which, in general, enjoyed a relative price advantage over vegetable oils in the United Kingdom.

Imports by the Other Western Europe region have been increasing slowly--only 1.4 percent a year. Moderate increases in rapeseed oil and olive oil production have partially offset the need for imports.

Japan's vegetable oil imports have been rising very rapidly, averaging some 10.2 percent a year from 1955-57 through 1963-65. This rise can be attributed to many factors, the main ones being a decline in domestic production, a rapidly expanding economy, and a low level of per capita oil consumption.

Among the LDC's, the most dramatic changes during 1955-57 through 1963-65 were the changes of the South Asia region and the North Africa and West Asia region from net exporters to net importers. Substantial population increases, moderate increases in oilseed production, and large levels of imports on a concessional basis characterized both these regions during the review period.

Trade Patterns

Table 8 presents the average 1963-65 data on trade flows of vegetable oils for 16 regions and shows region of origin and destination of exports. Tables 9 and 10 break down total trade flows into component parts of trade in oil as such and trade in oil, oil-equivalent basis. These tables are presented in tabular matrix form so that imports and exports among the 16 regions, and for the three divisions of the world, can be readily discerned. For example, the matrix shows that during 1963-65, the LDC's exported a total of some 3.3 million tons of vegetable oil (including oil-equivalent) with 2.8 million tons going to developed countries (84 percent), .2 million tons going to central plan countries, and the remaining .3 million tons being traded within the LDC region.

The matrix also shows that the EC imported an average of 2.3 million tons of vegetable oils during 1963-65, with 1.4 million tons coming from the LDC's, 0.1 million from central plan countries, and .8 million from developed countries. Of the 2.3 million tons of vegetable oil imports, 1.4 million were imported in the form of oilseeds. Of this, .53 million tons originated from developed regions, .05 million from central plan regions, and .83 million from LDC regions.

The above are but a few of the comparisons tables 8-10 permit. By assuming a trade flow among the exporters and importers based on these tables, a future flow of trade can be projected.

Trade in Animal Fats and Marine Oils

In analyzing trade patterns of vegetable oils, and subsequent demand, it is necessary and logical to examine exports and imports of the relevant vegetable oil substitutes--lard, butter, and marine oils (table 11). Because of problems in disaggregating data, the LDC's and Communist Asia were grouped together in the review of trade of these substitutes. Developed countries dominate trade in lard, butter, and marine oils. In 1963-65, they accounted for 87 percent of the total net exports and 93 percent of the total net imports.

The four leading export regions and their share of the net world exports for the mid-1950's and mid-1960's, respectively, were: (1) the United States, 40 and 35 percent; (2) Australia and New Zealand, 29 and 25 percent; (3) Other Western Europe, 21 and 19 percent; and (4) Japan, 7 and 8 percent.

The three leading importers in the mid-1950's and mid-1960's, respectively, were: (1) the United Kingdom, 67 and 78 percent; (2) the EC, 20 and 15 percent; and (3) Eastern Europe, 11 and 7 percent.

From 1955-57 to 1963-65, Russia and Canada changed from net importers to net exporters. As a group, the LDC's plus Communist Asia changed from a net exporter to a net importer.

4.--PRODUCTION OF VEGETABLE OILS

World vegetable oil production data are prepared by various organizations including the Foreign Agricultural Service (FAS) of the U. S. Department of Agriculture and the United Nations Food and Agriculture Organization (FAO). The data, however, are presented on a commodity rather than a regional basis. To obtain regional estimates, a world production series, by country, for each of the oilseeds of primary interest to this report was first prepared. For these data, estimates of regional vegetable oil production on an oil-equivalent basis were developed.

Production of Parent Materials

Annual increases in world production 8/ of vegetable oil-bearing materials during 1954-56 through 1965-67 were greatest for sunflowerseed and soybeans and lowest for palm oil, palm kernels, copra, and cottonseed (table 12). The last four products are grown primarily in the less developed countries.

Procedure for Computing Vegetable Oil Production

Deriving estimates of world vegetable oil production presents many problems inasmuch as the United States is practically the only country that reports national production systematically. For other countries, estimates of vegetable oil production were derived from the oilseed production figures compiled for each region. Estimates of the percentage of the crop crushed and a percentage oil-yield factor were applied to the quantity of oilseed to complete the estimate of vegetable oil production. The percentage of oilseed crops crushed varies widely among commodities and among countries. The crushing levels adopted for this report are those used by FAS. These levels, in turn, are based on world crushing levels developed by FAO (22).

A production crushing level of 100 percent was assumed for palm kernels because palm kernels are saved only when they are to be sold for eventual crushing and the unsalvaged kernels are not counted as produced. All copra produced was also considered available for crushing because copra represents the first stage in preparing coconuts for oil processing. In the absence of specific information, it is assumed that some 10 percent of each year's production of rapeseed, sunflowerseed, cottonseed, peanuts, and soybeans is retained for seed or is lost during marketing. Since very little of the rapeseed or sunflowerseed production is used directly for human or animal consumption, some 90 percent of the production of these crops was considered available for crushing. The crushing levels used for cottonseed, soybeans, and peanuts were generally below 90 percent, the differences being the amounts estimated as consumed directly by humans and/or livestock. Olive oil and palm oil production are reported on an oil basis and thus no crushing percentage level is required for them. Olive oil production is reported regularly by the major producing countries. Since palm oil output is especially difficult to determine, estimates of domestic consumption were added to commercial output.

Variations in the oil yields of oilseeds are not as divergent from country to country as are the variations in percentages of the crop crushed. The conversion rates for oilseeds to oil equivalent used in this study were adopted from an ERS

8/ The level of production of each oil-bearing product for 1954-56, 1960-62, and 1965-67, plus the rates of change for each region and for the world, are presented in the tables in app. B. Each oilseed is discussed in app. C.

report published in 1968 (42, table 94). These rates are a marriage of the rates used by FAS and FAO. Because the rates used in this report are not the rates used across the board by either FAS or FAO, the oil-equivalent levels of production vary somewhat from the levels of production contained in the reports of these two organizations.

Time Reference

Calendar year production of vegetable oils from domestic materials is officially reported in the United States and such data were used in this report. For all other countries, the net oil equivalent of an entire crop was allocated to the calendar year during which the crop's processing chiefly occurred. The oil equivalents of peanuts, soybeans, cottonseed, and sunflowerseed from oilseeds harvested in, say 1959, were included in the oil production of 1960. The oil equivalents of palm kernels, copra, and rapeseed were assigned to the calendar years in which the crops were harvested. Palm oil was also assigned to the year in which the palms were harvested. Olive oil production was assigned to the calendar year following the harvest season. Exceptions to the above were Canada, where the rapeseed oil equivalent was assigned to the year following rapeseed harvest, and South America, where the oil-equivalent production of the annual crops, except for rapeseed, was assigned to the year of harvest.

Assigning production to calendar years, of course, allows one to measure annual production with trade and consumption in the same time period. There is no easy division of supplies into one year or the next, inasmuch as oilseeds are grown throughout the world and harvest months vary from continent to continent. But trade is generally reported on a calendar year basis and by having production estimated on a calendar year basis, it is possible to arrive at apparent availability.

The net oil equivalent is assigned to the country where the oilseed is harvested. Often this is not the country where the oilseed is processed since many countries export a large portion of their oilseeds.

Regional Production of Vegetable Oils, Oil-Equivalent Basis

The less developed countries' share of total world vegetable oil production fell from 51 percent during 1955-57 to 45 percent by 1966-68 (table 13). This downward shift occurred primarily because of the slow growth of oil palms in the LDC's and the rapid increases in soybean production in the United States and sunflowerseed in Russia. During 1966-68, the United States accounted for 24 percent of the world's total vegetable oil production, while Russia accounted for an estimated 14 percent.

Data for 1955-68 production of oilseeds and their oil equivalent, by region, are presented in appendix B. A brief discussion of oilseed and oil-equivalent production in the major producing regions, and countries within the regions, follows herewith. Production data on cottonseed are presented in a separate report (43) and are not included here.

United States

Vegetable oils in the United States are derived almost exclusively from cottonseed, peanuts, and soybeans (app. table B-10).

Cottonseed production is controlled by acreage allotments on cotton production. Peanuts are also controlled by acreage allotments. Soybean production is not controlled, except soybeans may not be grown on land diverted from other crops under governmental control programs. Since 1956, the annual peanut acreage allotment has

been 2.4 million hectares. Because of increasing yields, however, production has been steadily increasing. The average yield per hectare harvested increased from 462 kilograms during 1955-57 to 775 kilograms during 1965-67--an annual rate of increase of 4.5 percent. The increase resulted primarily from improved varieties, better cultural practices, and more use of fertilizer. Based on present peanut technology, increases in peanut yields are expected to continue.

Peanuts in the United States are grown primarily for direct human consumption. The Government support price is for edible grade peanuts and is well above world prices for peanuts. The United States has a small role in the world trade of peanuts for crushing into oil and meal. Domestic crushings consist of low-quality peanuts and Government surplus peanuts. In the other major producing countries, peanuts are grown mainly for their oil and meal.

The phenomenal increase in U. S. soybean production since the early 1950's is well known. Production averaged 25 million tons during 1965-67, an average annual increase of 7.6 percent over the 1955-57 level (app. table B-3). The sharp increase in production has come about primarily through increased area planted. During 1955-57 through 1965-67, area planted increased at an average annual rate of 6.2 percent, compared with a 1.5 average annual increase for yields per hectare.

The level of soybean production is greatly influenced by the Government price support program. The key feature in the price support for soybeans is that the USDA's Commodity Credit Corporation (CCC) stands ready to make loans to farmers at rates corresponding to the support price and accepts the commodity as collateral. A farmer then has the option of redeeming the loan at any time up to maturity date, or of delivering the commodity at maturity in full satisfaction of the loan, regardless of the market price.

In general, market prices for soybeans have been above the support price; consequently, Government-held supplies are small. At the end of 1968, however, the quantity of soybeans placed under the CCC loan program reached an alltime high. To make U. S. soybeans more competitive, USDA in March 1969 lowered the soybean support price from $2.50 a bushel (No. 2 beans) to $2.25 (No. 2 beans). Presently, the United States is using more beans for domestic use and exporting more than in 1969.

Canada

Rapeseed production in Canada has continued to increase since 1955, with the exception of several years when plantings were reduced following low prices. Production, which is largely exported, reached a record level of 586,000 tons in 1966. Inasmuch as no support program operates in Canada, production is most sensitive to the world price of rapeseed oil to that of wheat, an alternative crop. In recent years, the rapeseed/wheat price ratio appears to have been generally favorable to rapeseed. Extensive cultivation with fairly low yields, but also low production costs, has meant that Canadian rapeseed production has been profitable at world market prices. Canada is the only major producing country where there are no support price measures in favor of rapeseed production.

European Community

EC production of vegetable oils--primarily olive oil and rapeseed oil--has increased steadily since 1955. France and Germany are the major producers of rapeseed oil. Under the EC's fats and oils regulations, which came into effect on July 1, 1967, there is a fixed "norm price" intended to represent a fair return to producers for their products, and an "intervention price" at which intervention agencies will buy all seed offered. The price at which EC crushers can buy domestic rapeseed is

free to vary between these two prices. For internal sales, deficiency payments equal to the difference between the norm price and the most favorable world price for rapeseed of the same quality are made to community buyers. For exports to third countries, a refund equal to the difference between actual community price and the world market prices is made. Beginning July 1, 1967, the EC "norm price" was $202.50 a ton and the "basic intervention price" was $176.50 a ton.

Prior to July 1, 1967, the German and French support prices were 15 percent below the present basic intervention price. The world price for rapeseed in 1967 averaged $122 a ton (Canadian 40 percent, c.i.f. European ports). Because of the increased producer price and recent improvements in rapeseed processing, EC rapeseed production has increased sharply in recent years--46 percent from 1966 to 1968.

Olive oil is produced primarily in Italy, where the number of specialized olive groves has been steadily increasing. The EC's fats and oils regulations also establish a norm price and a basic intervention price for olive oil. As with rapeseed, this policy isolates the producer price from the market price through guaranteed deficiency payments to producers. The guaranteed high price for the olive oil producer will most likely increase supply in the longrun. There are also support prices to EC producers for sunflowerseed, butter, butterfat, and pork.

Other Western Europe

The major vegetable oils produced in the O.W.E. countries are rapeseed oil and olive oil. The major producer of rapeseed is Sweden, where production and exports have continued to increase moderately.

The olive oil producers in this region, in order of importance, are Spain, Greece, and Portugal. The number of olive trees in these countries has increased only slightly since the early 1950's. Linear least squares trend analysis shows that olive oil production has been declining slightly in Spain and Portugal. There have been slight production increases in Greece, primarily because of improvements in yields per tree cultivated and some improvement in the oil yield of olives pressed.

Japan

Soybeans and peanuts produced in Japan are consumed directly as food. Rapeseed oil is the only domestically produced oil of significance. Yields per hectare of rapeseed have been relatively stagnant. The area planted to rapeseed during 1954-56 through 1966-68 declined--especially the irrigated area, where there has been a substitution to rice. Rapeseed production, oil-equivalent basis, declined 10.1 percent a year from 1954-56 through 1966-68.

Other Developed Countries

The remaining regions of the developed world include the United Kingdom, Australia-New Zealand, and the Republic of South Africa.

The United Kingdom produces practically none of the vegetable oils of primary concern in this report. Vegetable oil production in Australia-New Zealand consists of very small quantities of peanut oil and cottonseed oil. South Africa produces sunflowerseed oil and peanut oil. The South African Government encourages the production of both commodities through the use of price incentives. The goal is first to meet domestic needs and then to export what small quantities may be remaining.

Central Plan Countries

Vegetable oil in Russia and Eastern Europe is derived primarily from cottonseed and sunflowerseed. Production of sunflowerseed oil in the region from 1955 to 1968 increased nearly fourfold. The bulk of the expansion occurred in the USSR, but Bulgaria, Romania, and Yugoslavia also increased output markedly.

By area sown, sunflowerseed is now the most important crop of Soviet agriculture after grain and potatoes. The Russian Government has encouraged sunflowerseed production through economic incentives to producers. The increased production of sunflowerseed oil has come about as the result of four factors: (1) the area planted has increased notably; (2) of more significance, yields of seed per hectare have increased, largely following improved cultural practices; (3) new varieties with a much higher oil content have evolved; (4) the crushing industry has been modernized. More efficient extraction methods have led to higher oil yields at mills. In 1966, 72 percent of the sunflowerseed processed was solvent extracted, compared with 28 percent in 1958. The increase in sunflowerseed oil production in the East European countries has not been as great as that in Russia, although the new high-oil-yielding varieties are now extensively used in the East European countries.

Production of vegetable oils in Communist Asia declined an estimated 1.1 percent a year from 1955 to 1968. With respect to policies regarding agricultural production in Mainland China, first priority is given to grains, second priority to cotton, and third to oilseeds. Attempts to increase grain and cotton production have been primarily through area expansion. It is believed that this expansion may have come about at the expense of some of the oilseed crops (app. table B-19).

Latin America

Countries in Latin America produce all nine of the vegetable oils of primary interest in this report. The oil production of these crops increased at an average annual rate of 6.7 percent from 1955 to 1968. The great bulk of the oil produced is consumed within the region. From a trade point of view, the most important oils are sunflowerseed, soybeans, and peanuts.

The largest producer of sunflowerseed is Argentina. Production has not shown any distinct long-term expansion. There have been large year-to-year fluctuations, partly because of weather variations and changes in area planted often following changes in Government price support policies for sunflowerseed and alternative crops. Sunflowerseeds produced in Argentina are low in oil content compared with Russian sunflowerseed varieties.

Brazil is the region's major producer of soybeans and peanuts. Soybean production has expanded greatly since 1960. Production has been encouraged by favorable price supports. The increased production has come about primarily through expansion of area planted. Soybeans have become a good foreign exchange earner for Brazil, and the Government is expected to encourage further production. Brazil currently produces about four times as many peanuts as it did in the early 1950's. Increased area accounts for about three-fourths of the increase, while increased yields account for the remaining fourth. Price support for peanuts has been increased in recent years.

East and West Africa

The East and West Africa region is the world's largest exporter of peanuts and oil-palm products. The region's production of other oilseed products is considerably smaller and, in general, does not enter world markets.

The African oil palm is thought to be indigenous to West Africa, where it is found mainly in a belt 200-300 miles wide along the coast from Gambia to Angola. Most of the total area under oil palm consists of natural palm groves with very low yields. Modern plantations have been prominent in the Congo (Kinshasa) and West Cameroon. In recent years, plantation plantings have increased sharply--from 17,807 hectares in 1960 to 88,629 in 1968--in the Cameroon, Dahomey, Ivory Coast, and Sierra Leone.

Newly planted palms will begin producing at 4-5 years of age, but 9-10 years are required for maximum yields. The key factor in the replacement of natural groves by a "managed" system of new planting or rehabilitation has been the genetic breakthrough making available improved varieties. The new varieties have a yield potential exceeding that of unimproved strains by seven to ten times. In Africa, selection and breeding has concentrated on the Tenera type of palm, a hybrid from a cross of genetically different strains, namely Dura and Pisifera. The increased yields result from an earlier bearing age and from increases in the number of bunches, the percentage of fruit on the bunch, and the percentage of pulp in the fruit.

The change from traditional to modern methods of processing could result in a doubling of palm oil production without increasing the input of fruit. Thus, the economic importance of efficiency in processing is perhaps as great as that of the improvement in productivity of newly planted areas. At present, the bulk of the palm oil from the natural groves is processed by traditional methods. The old method of boiling and squeezing results in an extraction rate of approximately 30 percent, compared with 60 percent from the hand-screw press. Pioneer mills (digester-centrifuge-type processing units) have increased the oil yields up to 80 percent, but investment and labor requirements for the mills are high. With efficient processing, a modern plantation at full bearing level should produce about 15 tons of fresh fruit bunches per hectare, which in turn would yield 3.0 tons of palm oil and 0.75 tons of palm kernels. It is logical to assume that in future years an increasing portion of the produce from natural groves will be processed by modern methods.

Nigeria is one of the world's major sources of palm oil. Prior to the civil unrest in Nigeria, the Eastern region produced approximately 65 percent of the country's total palm oil. 9/ Practically all the palm oil is from wild or semiwild trees. In the former Eastern region, there are an estimated 1.1 million hectares of natural palm groves that vary widely in density. Yields of palm oil are very low, estimated at 109 kilograms a hectare. In the former Western and Mid-Western regions, there are an estimated 700,000 hectares with an average yield per hectare of 88 kilograms. Ownership of most of Nigeria's land resides with the tribes, and tribal chiefs assign to individuals the right to harvest the fruit from the natural palm trees. Thus, small holders harvest most of the palm fruit. Because of these practices, the trees in general are not well cared for, and there is little incentive for individual farmers to plant additional trees. In a study by Johnson (37), it has been argued that the low level of producer prices also retards the incentive for increased production. At past levels of producer prices, there have been unharvested areas of oil-bearing palms. The level of future production will depend heavily on new planting and rehabilitation schemes.

9/ The four regions of Nigeria were divided into 12 states in 1967. However, since historical data are available only in reference to the four regions, the discussion herein refers to the former Eastern, Mid-Western, Western, and Northern regions.

Oil palms in the Congo (Kinshasa) are primarily in plantations. In 1958, there were 235,000 hectares in plantations. After independence in 1960, new plantation plantings were sharply curtailed. Because of the rebellions of 1964 and 1965, many planters were forced to leave their plantations and as a consequence production fell sharply--from 245,000 tons in 1959 to 130,000 tons in 1965. Without a major replanting program, the Congo will not attain preindependence levels of palm oil and palm kernel production. There are various reasons for this. World prices for palm oil were so low in 1968-69 that young people in various areas of the Congo have not considered it worthwhile to gather the wild palm fruit. Also, plantations are experiencing difficulties in keeping a labor force--partly because of low wages and low palm fruit prices and partly because young men prefer not to do field work. The plantations that were abandoned will probably never attain previous levels of output because the trees are now older and they receive less management and care. Also, crop research and selection of high-yielding varieties adapted to the Congo have advanced little since 1960, while progress has been made in other countries. Only a small percentage of the present plantations are planted to the high-yielding Tenera cross variety.

In Africa, palm kernels from natural groves constitute about 7 percent of the total weight of the palm bunch. In the case of the Dura Pisifera cross, the palm kernel accounts for only 5 percent of the total weight of the bunch. However, because of increased per hectare yields of bunches, under favorable conditions the hybrid yields around 181 kilograms of kernels per hectare, compared with generally less than 136 kilograms for natural palm groves.

West Africa is one of the world's largest producing areas of peanuts. Nigeria and Senegal rank third and fourth, after India and Mainland China, among the world's largest producers. Other large producers of peanuts in West Africa include Niger, Cameroon, and Gambia. Nigeria and Senegal together account for about [illegible] of the world exports.

Nigeria's peanut industry is centered in the former Northern Region. Although the region comprises 79 percent of Nigeria's total land area, only about 12 percent of the region is in farm crops. The amount of additional land that could be brought under cultivation is unknown, but it is several times that currently cultivated. Land use is largely based on shifting cultivation. Near large urban areas, permanent cultivation is practiced. Around Kano, for example, about 405,000 hectares are cultivated without periods of fallow. The use of the land in the Northern Region is generally alloted to family groups, and a given family usually retains its rights to again cultivate a specific plot after it has lain fallow.

Accurate figures on peanut area and yield are not available. The Nigerian Government has estimated the increase in area to be at 2 percent per annum. The acreage planted to peanuts varies from year to year depending on planting and growing conditions early in the season. If the rainy season arrives early, and if the farmer can plant his food crops early and get the crops off to a good start, he will probably plant an increased hectarage to peanuts. If the rains come late and the crop outlook is poor, he will first plant his food crops and devote more hectarage to them. The result is that the peanuts will be planted later and the area will be reduced. High yields depended greatly on getting the crop planted early.

The Marketing Board establishes the producer price and controls the marketing process of peanuts in Nigeria. Through 1968, prices were announced after the planting season.

The Senegalese economy relies fundamentally on the production and export of peanuts. Of the total cultivated area in Senegal, approximately 50 percent is devoted to peanuts. Peanuts provide nearly 75 percent of the country's exportable resources;

and some 85 percent of the labor force is employed in production and marketing of the crop. The implements used for cultivation are largely hand tools. Individual titles to agricultural land are almost nonexistent. Most farms are farmed by individual families. Senegal's association with the EC led to the abolition of the privileged tariff (20 percent above the world price) that was enjoyed by countries exporting peanuts on the French market.10/ Alignment of the price of exported peanuts with the world price has required a reduction in producer prices. However, peanuts are one of the rare exportable items of the savannah regions of Africa and it is likely that their production will continue to increase in face of declining producer and export prices.

North Africa and West Asia

Vegetable oil production in North Africa and West Asia has been increasing steadily since 1955. Cottonseed, olive oil, peanuts, and sunflowerseed have all contributed to this increase.

The major producers of cottonseed are the United Arab Republic, Sudan, and Turkey. The only sunflowerseed producer of significance in the area is Turkey. Turkey's sunflowerseed production was relatively low in the early 1960's because of pest infestation. Production reached a record high in 1967 because of the use of more resistant Russian varieties with a significantly higher oil yield. Very little of the cottonseed oil or sunflowerseed oil produced in the region enters into world markets.

Production of peanuts is centered in Sudan, where they are grown almost exclusively for export. In 1963, peanuts became the second most important earner of foreign exchange. The principal production areas have been the sandy provinces of Kordofan and Darfur, where there are large variations in rainfall and yields. A recent development, the production of peanuts on the irrigated soils of the Gezira, was a result of attempts to increase the output of the Gezira by replacing with alternative crops some of the fallows in the original cotton-orientated rotations. Peanuts were found to be suitable and profitable. Peanut acreage in the Gezira increased from 14,286 hectares in 1962/63 to 50,426 hectares in 1965/66. In the absence of unfavorable changes in the world market situation, expansion of production in the future will be large, especially in the Gezira and in the large areas expected to come under irrigation during the 1970's. The level of producer prices in the country has been largely determined by the level of world prices.

Production of olive oil in the North Africa and West Asia region is centered primarily in Turkey, Tunisia, and Morocco. In Turkey, the total number of olive trees has been doubled since the end of World War II. Since the early 1960's olive tree plantings in Turkey have been increasing at the rate of about one and a half million trees a year. In Tunisia, the total number of olive trees has been increasing around 2.8 percent annually since 1950. The number of productive trees in Morocco has increased only slightly since 1950.

Pacific Islands and Asia, excluding West Asia

Four of the 18 regions in this study are in Asia. South Asia's oilseed production from 1955 to 1968 increased 2.2 percent annually, or approximately at the same rate as population. Practically all of the vegetable oil produced in this region is for domestic consumption. India is the largest producer of peanuts in the world.

10/ The loss of this privileged tariff applies to all of the African countries that were former French colonies and that are now associated with the EC.

In Southeast Asia and the Other Asia and Pacific Islands regions, oilseed production from 1955 to 1968 increased an average of 2.0 percent annually. The major crops produced for export are coconuts and oil palms.

Production of coconuts is concentrated in the Philippines, where they are the country's leading commercial crop. There are some 440,000 coconut farms in the country with a total area of some 1.9 million hectares. The average farm size is 4.4 hectares. During 1955-66, production increased 3.9 percent annually. Production dropped sharply in 1967 because of typhoon damage. The area planted to coconut trees has increased substantially since 1960. Approximately 66 percent of the trees were in various stages of bearing in 1968. Productivity per hectare continues to be rather low; contributing factors have been the slow rate of replanting of old trees in the smaller sized farms and the dreaded "cadang-cadang" disease of coconut.

Malaysia and Indonesia are the major producers of oil palms in the region.

Malaysian oil palm plantings began increasing sharply in 1961. The area under oil palm nearly tripled from 57,000 hectares in 1961 to 160,000 hectares by 1967. In 1966, Malaysia became the world's largest exporter of palm oil. Production is mainly on large estates that have adjacent processing facilities. Oil palm production has been encouraged by the Government, primarily because of declining rubber prices. The rate of future expansion in area will most likely be governed by the relative profitability of oil palm to rubber since there is a potential large area having suitable soils and climate for both. Oil palm plantings since 1960 have been of the higher yielding Tenera cross variety (Deli dura x Pisifera), which has a much higher proportion of pulp to kernel. Palm oil production has been increasing much more rapidly than palm kernel production.

Indonesia has been the world's second largest exporter of palm oil since 1965. As in Malaysia, the bulk of the palm oil is produced on estates. There were only limited increases in production during 1955-66 because of inadequate replanting and lack of financial resources to purchase fertilizer and other necessary inputs to maintain established estates. In recent years, however, more attention has been given to replanting. In 1963, 34 percent of about 105,000 hectares under oil palms were over 20 years of age, while by 1967 the proportion had been reduced to 24 percent.

World Production of Edible Fats and Oils

World production of fats and oils that are used primarily for edible purposes increased at an estimated average annual rate of 2.9 percent from 1955-57 through 1966-68. Inasmuch as the world population was increasing 2.0 percent a year during this period, there was an apparent increase on a global basis in the per capita availability of fats and oils. During the period, production of the soft edible vegetable oil group increased at the fastest rate, 4.3 percent a year. Butter, lard, and marine oils each increased at an average rate of 1.9 percent, while production of palm oil was practically constant.

During 1955-57 through 1966-68, the soft edible vegetable oils' share of world production increased from 45 to 53 percent. The increase is primarily attributable to increases in soybean and sunflowerseed production. The other fats and oils' share of total production declined. Palm oil's share of the total declined from 20 to 16 percent, butter and lard's share from 31 to 28 percent, and marine oils' from 4.4 to 4.0 percent.

World Production of Animal Fats and Marine Oils

Data on production of butter, lard, and marine oils were obtained on a regional basis for the same periods as data on regional trade, 1955-57 and 1963-65 (table 15).

Developed countries supplied some 61 percent of the world's production of animal fats and marine oils during 1955-57, compared with 54 percent in 1963-65. Overall production in developed countries increased only 0.4 percent annually, primarily because production declined in the United States and the United Kingdom.

Production in the USSR increased an estimated 6.9 percent a year. In the LDC's and Communist Asia, production increased an estimated 1.7 percent annually--well below the rate of population increase.

5.--CONSUMPTION OF FATS AND OILS

In general, regional patterns of consumption of fats and oils reflect regional patterns of production. For example, the United States uses mostly soybean and cottonseed oils in margarine, cooking, and salad oils; in Russia, cottonseed and sunflowerseed oils are major edible oils. Coconut and palm oils are prominent in the diet in East Asia, while in West Africa, palm oil is a major source of edible oils. Scandinavians consume primarily rapeseed oil and marine oils and in Australia and New Zealand, animal fats predominate. The locally produced fats and oils are generally in a favored position because of a combination of protective economic policies, lower transportation costs, and consumer habits and preferences that favor the local products (28, p. 7).

In the major importing regions, such as Western Europe and Japan, the number of edible fats and oils of importance is quite large. As would be expected, consumption in the high-income countries is generally spread over a wider range of fats and oils than in the countries with low and medium incomes.

The level of consumption of all fats and oils is largely determined by the level of incomes (26, pp. 41-42). As illustrated in figure 2, per capita consumption of fats and oils in countries with a per capita GDP in excess of $1,000 is generally more than 20 kilograms. In countries with a per capita GDP below $500, consumption is generally below 10 kilograms. 11/ In these low- and medium-income countries that have had a substantial increase in income since the middle 1950's, there has been a significant increase in fats and oils consumption. This, of course, indicates that the income elasticity of demand is high in countries where the per capita consumption is low. In the high-income countries, where consumption of fats and oils is approaching saturation levels, there is little increase in total consumption with increased income. However, while total consumption has not been increasing markedly in these countries, there have been some important variations in the patterns of consumption. These variations have been caused by a number of factors, including relative prices, consumer habits, health considerations, protection granted to domestic producers and manufacturers, regulations affecting margarine production, technical and financial characteristics of the highly integrated fats and oils processing industries, and traditional links with suppliers.

Consumption of Vegetable Oils

For this study, figures on total and per capita consumption, or availability, of vegetable oils were developed for each region from 1955 to as far forward as data permitted. For the United States, the consumption series is based on actual human consumption. For all other regions, consumption is based on domestic production plus or minus the region's net trade. The latter definition excludes consideration of stock changes and includes production for both edible and industrial purposes. A consistent time series on vegetable oil inventories was available for only the United States. However, the effects of annual oil stock variations on consumption have probably been relatively small for most regions. While it was recognized that a portion of the nine oils of prime concern to this report were used for industrial purposes, data were not available that would permit a division of oils in each region into industrial and edible categories. In the United States, for which such data were available, less than 2 percent of the total utilization of the nine vegetable oils was for industrial purposes; coconut oil formed the bulk of this use. Utilization data for other countries also showed a very small proportion of the oil being used for industrial purposes. The share used for industrial purposes was much higher for the animal and marine fats and oils. While some of the nine vegetable oils are used more for industrial purposes

11/ This is "visible" consumption because it excludes consumption of fats and oils obtained through the eating of meat and fish and through the direct consumption of oilseeds as such.

than others are (for example, coconut oil and palm kernel oil), overall demand for the nine oils as a group is primarily for edible purposes.

Total world availability of vegetable oils during 1955-57 through 1963-65 grew at a rate of some 3.1 percent a year (table 16). For the developed regions as a whole, the annual growth rate was 3.2 percent, compared with 3.0 percent for the central plan countries and 3.2 percent for the less developed countries. On an actual consumption basis, per capita availability of vegetable oils during 1963-65 averaged 11.8 kilograms for the developed regions, 3.3 kilos for the central plan countries, and 4.5 kilos for the LDC's.

As a percentage of total world vegetable oil consumption, some 43 percent is consumed in the developed countries, 20 percent in the central plan countries, and 37 percent in the LDC's. The world's major consuming region is the United States, followed by the EC, South Asia, the USSR, and Latin America, respectively.

Consumption of Animal Fats and Marine Oils

The less developed countries lag considerably behind the more economically advanced countries in consumption of animal fats and marine oils. In the LDC's plus Communist Asia, estimated per capita availability of these products during 1963-65 was only 0.76 kilos. For the developed regions, average per capita consumption was 8.2 kilos. This was about the same level as that in Eastern Europe and Russia--8.0 kilos.

Among the developed regions, per capita consumption declined in the United States, Canada, Other Western Europe, Australia-New Zealand, and South Africa during 1955-57 through 1963-65. The annual rate of decline was greatest in the United States, 4.3 percent, and least in Other Western Europe, 1.0 percent. In contrast, increases in per capita consumption occurred in the EC, the United Kingdom, and Japan. Although per capita availability in Japan increased 6.4 percent a year, apparent consumption was still only 1.9 kilos during 1963-65. In the United Kingdom, consumption has been increasing 2.7 percent annually, but per capita availability was 17 kilos during 1963-65.

In Russia, per capita consumption of lard, butter, and marine oils was an estimated 7.3 kilos in 1963-65, compared with 5.1 kilos in 1955-57. Per capita consumption in Eastern Europe increased by 1.6 percent annually during 1955-57 through 1963-65, reaching 9.4 kilos by 1963-65.

6.--DEMAND ANALYSIS AND PROJECTIONS FOR VEGETABLE OILS

Analysis

Theoretically, per capita demand for a commodity depends on its own price, price of its substitutes, level of income of the consumer, and factors that affect demand over time, such as tastes and preferences. Thus, $Q^d = f(P, P_{sb}, I, T)$, where:

Q^d = quantity demanded

P = price of commodity

P_{sb} = price of substitutes

I = income

T = trend

To measure the effects of the above economic factors on demand for vegetable oil, least squares estimates of a single equation were used. Arguments for this procedure in estimating the demand for agricultural products are given by Fox and Ezekiel (25, ch. 24). A demand analysis was made for each of the 18 regions. To provide a sound basis for projecting demand, several functions were developed for each region.

The dependent variable was per capita consumption of vegetable oil and, except for the United States, represented the sum of a region's production and net trade divided by the region's population. For the United States, actual per capita consumption data were used.

The independent variables taken into consideration were:

(1) Price of the commodity. A representative retail or wholesale price series was found for only the United States; the series began with 1955. For the other regions the available partial retail or wholesale price series of individual oils was compared with the international price series shown in table 3. In general, these two price series were found to move in the same direction. This finding supported our contention that developments in the production of a particular vegetable oil in one part of the world affect the price, and thus the demand, for other vegetable oils there and elsewhere. Thus, regional average price series, weighted by the volume and international price of each oil imported, or exported if a net exporting region, were constructed. For some regions, the international price series of the most significantly exported, or imported, oil provided a better statistical fit. These price series were deflated by a representative regional consumer price index where available. For regions for which such a price index was not available, the import or export price index (as published by the International Monetary Fund (36)) of a major country within the region was used.

(2) Price of substitutes. For each region, the price of a competing product--generally either lard, butter, or fish oil--was also introduced as an explanatory variable. To the extent possible, retail or wholesale prices for the major competing commodity within the region were used. Where data on such prices were not available, data on international prices were used. International prices of the substitute commodity were deflated in the same manner vegetable oil prices were deflated.

(3) Income. The following measures of national income growth were taken largely from Moe (44) and used as the income variable: For developed regions, per capita consumer expenditure in constant prices; for Eastern Europe, a deflated index of the "dis-

tributed national income" of Poland; for the USSR, deflated "net material product"; and for Communist Asia, an income series developed by the Committee on the Economy of China (6).

(4) Trend. Changes in tastes, in the composition of the population, and in the distribution of employment between the urban and rural sectors may alter the composition of consumption. Since most of these changes are gradual, they might be explained as trend. However, the income and trend variables are so strongly intercorrelated that it is not possible to introduce both. When trend is excluded from the analysis, the income coefficient represents not only income but also the trend effect. (54, pp. 41-45).

The following functions were used in the demand analysis for vegetable oil: 12/

(a) $Q_o^d = a + b\,P_o + c\,P_{sb} + d\,I + e$

(b) $\log Q_o^d = a + b \log P_o + c \log P_{sb} + d \log I + e$

(c) $Q_o^d = a + b \log P_o + c \log P_{sb} + d \log I + e$

(d) $\log Q_o^d = a + \frac{b}{P_o} + \frac{c}{P_{sb}} + \frac{d}{I} + e$

where:

Q_o^d = per capita consumption of vegetable oil measured in kilograms

P_o = price of vegetable oil

P_{sb} = price of substitute product

I = per capita income

e = unobservable random term

a, b, c, and d = parameters

log denotes common logarithms (base 10)

No lagged relationships were considered in any of the functions. As with most food product studies that use annual data, it is assumed that the adjustment in consumption following a change in price or income takes place in the same year, and that price or income changes in previous years or expected in future years have no effect on current consumption.

Table 18, which shows the various demand regressions that were developed for each region, contains for each function (1) the value of the "F" statistic and a notation on whether the statistic is statistically significant at the 5-percent confidence limit, (2) the value of the Durbin-Watson statistic, (3) the value of the standard error of the estimate, and (4) "t" values for each of the independent variables. The price, cross, and income elasticities, as obtained from the various regressions, appear in table 19. The elasticities that are significant at the 1-, 5-, and 10-percent levels are noted. Further discussions of these regressions are incorporated in the following section on projections.

12/ For a description and interpretation of these functions, see Goreux (29).

Projections

The vegetable oil demand projections, which are based on the statistical equations developed earlier in this chapter, are presented in table 20. Vegetable oil prices and the price of vegetable oil substitutes were assumed constant at average 1963-65 prices. (The assumption of constant prices, however, is relaxed in the projections of supply and demand made in part IV of this report.)

Income and population data used in the projections appear in appendix D. In the selection of a regional equation for projection purposes, consideration was first given to the reasonableness of the signs of the coefficients. In accordance with economic theory, one would expect a negative sign for price and a positive sign for both price of substitutes and income. The statistical significance of the "F" and "t" values were important guides in selecting a function. Further guides included the values of the Durbin-Watson statistic and the coefficient of determination, and measures to evaluate heteroscedasticity. Multicollinearity was taken into account only when the standard error seemed unreasonably large relative to the coefficients.

As indicated in chapter 5, while there have been important variations in the consumption patterns of fats and oils in the developed regions, total consumption there is approaching saturation levels. For these regions, a slowing down in the percentage rate of increase is likely as more people move into the higher income groups where per capita consumption levels off. For this reason, the log-inverse or semi-log function is most applicable for projections for these regions. For regions where per capita consumption of fats and oils is quite low and is not expected to level off before 1980, the linear or double-log function is the more appropriate for projecting consumption.

The final selection of a function for projection purposes should also, of course, include reasonableness, and here judgment must be introduced. For instance, data on the United Kingdom indicate per capita consumption of vegetable oil has been declining. Is it reasonable to assume that such consumption will continue to decline through 1980? No objective procedure was found for making the decision, but it was decided on a judgment basis that consumption would not continue to decline, considering indications from other studies (see below, p. 53).

A number of separate studies provided demand projections for vegetable oil in many countries. These are noted in the Literature Cited (p. 134). The findings of these studies were taken into consideration in arriving at projected regional estimates of vegetable oil consumption.

Regional Demand

United States.--The U.S. price variables consist of the wholesale index price of vegetable oil and the wholesale index price of lard.

All three of the functions developed for the United States were statistically significant with high R^2s. The income elasticity for all functions was around 1.0, which seems much too high for a developed country. Therefore, a regression was made on the consumption of animal fats and marine oils and per capita expenditures during 1955-67. The regression indicates that while total per capita consumption of fats and oils was relatively constant, there was a steady increase in vegetable oil consumption at the expense of animal fats and marine oils.

For the period of fit, any of the three functions seems reasonable. The log-inverse function, which provides for a saturation level, was selected primarily because it gave what seems the most reasonable projection--a slightly lower consumption level than projected under the other two functions. The projected per capita consumption

level of 18.2 kilos of vegetable oil by 1980 assumes a continual substitution of such oils for animal fats and marine oils plus a moderate increase in total per capita consumption of fats and oils.

Canada.--Several vegetable oil price series were tried in the mathematical functions for Canada. The best price series, from a statistical point of view, were obtained by weighting the quantity of vegetable oil imports by the value of such imports. For the price of substitutes, butter prices were used. The statistical significance of the explanatory variables was greatly improved when rapeseed oil was deleted (around 1 kilo per capita annually) from the consumption level. The initial result may have been due to rapeseed stock variations and special factors affecting industrial use.

The semi-log function was selected for projection purposes. Per capita consumption is projected to reach 10.2 kilograms by 1980 (excluding per capita consumption of rapeseed oil). Income was the most statistically significant variable, while the coefficient of determination (R^2) was 0.73.

European Community.--The EC price variable was the price of soybean oil, c.i.f. Hamburg, and the price of substitutes was lard prices. Income was significant at the 1-percent level. The price coefficients were not significant.

The semi-log function was selected for projection purposes. The "F" value was 16.5 and the R^2 was 0.85. Per capita consumption for the EC for 1980 is estimated at 16.7 kilos, which is in line with the estimates of other studies projecting vegetable oil consumption for the EC.

United Kingdom.--The U.K. vegetable oil price variable was a weighted average price of annual vegetable oil imports. As a price for substitutes, lard prices were a much better explanatory variable than butter prices were.

For all three functions developed for the United Kingdom, the sign of the income coefficient was negative. This was as expected, however, since per capita vegetable oil consumption has been declining while income has been increasing. With a negative income sign and the assumption of constant prices, the projected level of vegetable oil consumption becomes lower than it was during the historical period.

U.K. consumption of animal fats (lard and butter) has increased, primarily because their prices have been favorable relative to those of most vegetable oils. The price relationship has existed, in large part, because of the surplus supply of animal fats and oils in the EC and the surplus of butter in New Zealand, a country which enjoys Commonwealth trade preferences.

A continuation of declining vegetable oil consumption and increasing animal fat consumption through 1980 seems questionable. Supporting this opinion is an FAO study that projects constant per capita consumption of vegetable oils and moderate increases in butter consumption in the United Kingdom through 1985 (14). An OECD study projects constant per capita consumption of butter in the United Kingdom (47). The FAO study assumes constant prices, while the OECD study assumes continuation of past trends in prices.

One assumption of the present report is that a large surplus supply of animal fats in the EC and New Zealand will not continue through 1980. Therefore, per capita consumption of vegetable oil in the United Kingdom will probably increase in the future because the price relationships between vegetable oils and substitutes will change. By 1980, the price of substitutes will increase by an estimated 10 percent relative to that of vegetable oil. Based on this assumption and the semi-log function, per capita vegetable oil consumption is estimated to increase from some 9.2 kilos in 1963-65 to 9.8 kilos by 1980.

Other Western Europe.--A large number of functions were developed for the O.W.E. region, most of them yielding statistically unsatisfactory results and/or wrong signs. Consequently, the olive oil consuming countries (Spain, Greece, and Portugal) were treated as a separate area because their oil consumption habits and levels are quite different from the other O.W.E. countries. The resulting equations for the two areas had correct signs and provided better statistical fits. Olive oil prices were used for Spain, Greece, and Portugal, while soybean oil and lard prices were used for the other countries.

For the three olive oil consuming countries, the log-log function was selected for projection purposes. Consumption is estimated to increase from 17 kilos in 1963-65 to 19.4 kilos by 1980. For the other countries, a semi-log function best met the criteria of statistical fit and reasonableness. The equation indicates that per capita consumption for these countries will approach 8.8 kilos by 1980.

With the two demand projections, combined per capita consumption for the region is estimated to reach 14.3 kilos by 1980, compared with 13.0 kilos during 1963-65.

Japan.--The most meaningful price series for Japan was a weighted average price of vegetable oil imports. Fish oil, lard, and butter prices were all tried as price of substitutes but none yielded the correct sign in accordance with economic theory. The demand functions developed for Japan therefore excluded the price of substitutes.

The semi-log function was selected for projection purposes. The income variable, as expected, was highly significant. Per capita consumption is projected to reach 7.0 kilos by 1980.

Australia and New Zealand.--The international price of coconut oil--the main imported oil--was the price of oil. Butter prices were used as the price of substitutes.

The linear function was used for projecting because consumption is expected to increase in line with past linear trends. The "F" value was significant at the 5-percent level. The income variable was also significant at this level, while the price variables were not. Per capita availability is projected to increase from 4.0 kilos during 1963-65 to 7.0 kilos by 1980.

Butter consumption in these two countries is very high, but appears to be declining on a per capita basis. Australia places quotas on table margarine production. However, since there are no restrictions on margarine use in baking, its use for this purpose has been steadily increasing. The above projection assumes a loosening of table margarine production quotas and a continued increase in the use of vegetable oils, except in table margarine.

South Africa.--Peanut oil prices were chosen to represent the price of oil, and butter prices were used as the price for substitutes.

The linear function, which gave the best statistical fit for this region, was selected for the projections. By 1980, per capita vegetable oil consumption will reach 4.5 kilos.

Eastern Europe.--Consumption levels in the central plan countries are largely determined by policy and administrative measures. Thus, estimating future consumption by a trend analysis is hazardous. On the assumption that income is an indication of consumer demand and has some influence on actual consumption, a linear function was developed using sunflowerseed oil prices and income as independent variables. The variables had the correct signs according to economic theory and yielded a significant "F" statistic. Based on this function, per capita consumption is projected to reach 8.8 kilos by 1980.

As an alternative, an equation with consumption as a function of production was developed. The equation was highly significant, yielded an R^2 value of .89, and projects per capita consumption to increase sharply, reaching 12.2 kilos per capita by 1980. The rapid increase would probably occur because (1) vegetable oil production is projected to increase faster than population; and (2) historically, the region has been an importing region--thus, domestic production has been consumed almost entirely within the region.

A review of agricultural studies and the stated goals of these countries suggests that the function using vegetable oil prices and income yielded a reasonable projected level of consumption (8.8 kilos per capita).

USSR.--In Russia, the retail price of vegetable oil has not changed since 1956. Since the price of vegetable oil is determined by the Government, price variables were not considered in equations developed for the USSR. Functions that were developed to see if a crude relationship existed between income and consumption were not statistically significant. A regression was made to ascertain the relationship between domestic production and consumption. Production is a reasonable variable to use for projecting consumption in an exporting region, provided the level of exports has not fluctuated sharply. The regression equation, which was significant at the 5-percent level and yielded an R^2 value of 0.79, was selected for projection purposes. It indicates that per capita consumption will reach 13.0 kilos by 1980, compared with 8.6 kilos in 1963-65. Upon considerations similar to those for Eastern Europe, it was concluded that this projection was reasonable.

In Russia, there undoubtedly are people who would like to improve domestic consumption levels and others who want to hold domestic consumption down and earn foreign exchange through the sale of oil. By projecting consumption as a function of production, the assumption is implicitly made that future Soviet policy will not change significantly with respect to the share of production the consumer was allowed to have during 1955-65.

Communist Asia.--As expected, income was not a good explanatory variable of vegetable oil consumption in Communist Asia. Communist Asia apparently gives first priority to meeting its export commitments of oilseeds and oilseed products, and the remaining production is consumed domestically. Therefore, a linear function was developed with production as the independent variable. The function had a highly significant "F" value of 40.1. Based on this function, a 1980 per capita consumption level of 1.4 kilos is projected.

Central America and Mexico.--Peanut, soybean, sunflower, and cottonseed prices were all used as a price for vegetable oil but none yielded a correct sign. Lard prices were used as the price of substitutes. Equations 12 and 12b in table 18 are for cottonseed oil prices.

A function with production and income as the independent variables gave the best statistical fit and was selected for projection purposes. Per capita consumption by 1980 is projected to increase by 1 kilo over the average of 5.0 kilos during 1963-65.

South America.--Of the three functions developed for South America, the linear form provided the most reasonable projection. The "F" value was 17.5 and the R^2 value was 0.88. The price variables were more significant in this region than they were in most other regions. Based on the linear function, the projected level of per capita consumption for 1980 is 6.2 kilos.

The price variables used were soybean oil and lard prices.

East and West Africa.--Available data indicate that vegetable oil production and consumption have been increasing at a rate lower than the rate of population increase. Thus, regression analysis, with per capita consumption as the dependent variable, results

in a negative coefficient for both income and production. If used for predictive purposes, therefore, the regression equations would indicate a continued decline in consumption. The authors do not believe such a decline is possible, nor is it considered possible in available studies that have projected vegetable oil consumption for East and West Africa, or parts of the region.

FAO's 1966 report on commodity projections uses an income elasticity of around 0.7 in projecting vegetable oil demand for East and West Africa (14). Based on this elasticity and the income projections for this region (44), per capita consumption would reach 7.8 kilos by 1980, compared with 5.0 kilos in 1963-65. The projected level, however, may be considered potential demand, not actual consumption. These two measures are the same only if supplies are available to meet the projected demand.

Berg estimated total vegetable oil consumption and production in the three main vegetable oil producing countries of West Africa to increase by some 2.9 percent a year from the early 1960's through 1975 (3). FAO's Indicative World Plan, Regional Study on Africa, South of the Sahara (16) makes an intensive analysis of 24 countries. The study establishes production targets by countries. If a series of recommended practices is followed, vegetable oil production is estimated to increase by some 3.3 percent a year, and total consumption by an equivalent rate. Based on FAO's total consumption figure, per capita consumption would reach 5.7 kilos by 1980.

It is our estimate that from 1963-65 to 1980, vegetable oil consumption in East and West Africa will increase by an average of 2.8 percent a year, while production will increase by 2.6 percent.

To assume that total consumption will increase in line with production, or at 2.6 percent, would mean that there would be relatively no increase in consumption per capita because population is projected to increase by 2.5 percent per year. An implied income elasticity of practically 0 seems unreasonable during the next decade because (1) a portion of the population is expected to cross over from the subsistence to the market economy, and (2) the population in urban areas is expected to increase at a rate twice as fast as the total population. Vegetable oil consumption among the rural and urban populations will probably increase rather substantially by 1980. Therefore, total consumption is placed slightly above total production.

The difference between the growth rates of vegetable oil production and consumption is expected to be increasingly met by exporting countries within the region. Increased intraregional trade does not mean reduced export levels for the exporting countries, but it does mean the net export level of the region will decline.

North Africa and West Asia.--A weighted average price of cottonseed, soybean, and peanut oil imports was used as the price variable. No price substitute was introduced since there is little commercial trade in products competing with the region's vegetable oil.

Price and income variables were very good explanatory variables. Based on the linear equation, which had an R^2 value of 0.94 and a "F" value of 62.3, per capita consumption is projected to increase from 4.7 kilos in 1963-65 to 6.4 kilos in 1980.

South Asia.--The price variables were peanut oil and lard.

Linear and double-log functions were developed, both yielding an R^2 value of around 0.30. Income was a better explanatory variable than were the price variables. Based on the log-log function, a per capita consumption level of 4.8 kilos is projected for 1980. Per capita consumption during 1963-65 averaged 3.5 kilos. The 4.8 kilos projection appears reasonable in comparison with FAO and various country study projections.

Southeast Asia.--Coconut oil is the major oil consumed in Southeast Asia and consequently its prices were used as the price for vegetable oil. Lard prices represented the changes that have been occurring in prices of substitutes.

Prices and income were both weak explanatory variables. Production of vegetable oil has been increasing slowly, while the region has switched, on a net basis, from an exporter, to an importer, to an exporter. Primarily because of such trade variations, there have been rather sharp changes in the annual per capita availability figures. The variation in availability is most likely a major reason for the rather poor statistical fit of the different functions. However, based on the linear function, the projected level was considered to be reasonable and was therefore accepted. During 1963-65, Southeast Asia had the lowest per capita consumption level of vegetable oils among the less developed countries--2.0 kilos. For 1980, per capita consumption is projected to reach 2.3 kilos.

East Asia and Pacific Islands.--This region, like the East and West Africa region, was characterized by declining per capita consumption during 1955-65. Production used as an explanatory variable for consumption was statistically unsatisfactory. Income, of course, had a negative sign when used as an explanatory variable. The possibility of a continued decline in consumption was based on the following considerations.

In the FAO commodity projections study (14), the income elasticity coefficients used for projection of vegetable oil consumption were: Philippines, 1.2; Taiwan, 1.0; South Korea, 1.5; Indonesia, 1.0; and Malaysia, 0.7. The elasticity coefficient FAO used for Malaysia was most likely based on a Malaysian agricultural economy study (8) that develops an income elasticity of .66 for vegetable oils. FAO's Indicative Plan, Regional Study on Asia and the Far East, makes a detailed analysis of various countries including Taiwan, Korea, Malaysia, and the Philippines. That report proposes targets for increases in vegetable oil consumption of some 1.9 percent per capita for 1962-75. In the present report, the proposed FAO target is considered as the upper limit for possible future increases in vegetable oil consumption. Based on the 1.9-percent annual increase, consumption would reach 8.8 kilos per capita by 1980.

Upon consideration of the supply and demand factors of vegetable oil in the major countries in East Asia and the Pacific Islands, it was concluded that the rate of increase in per capita consumption will be about 1.0 percent a year, or reaching 7.3 kilos by 1980. Based on the expected rate of population increase, 2.4 percent a year, total consumption for the region is therefore projected to increase by 3.4 percent annually.

Inasmuch as the growth in total availability during 1955-65 was less than 2 percent, an estimated growth rate of 3.4 percent appears high at first glance. However, vegetable oil production in the region is expected to increase sharply in the years ahead, which will result in increased availability. Also, the increase in per capita consumption of 7.3 kilos implies an income elasticity coefficient of only 0.2. The implicit use of such a low elasticity would indicate that the subjective judgment made herein is not overly optimistic.

World Demand

Total world demand for vegetable oil is projected to reach 29.7 million tons by 1980, an average annual increase of 3.1 percent from the 1963-65 consumption level. Total consumption is projected to increase by 4.0 percent a year in the less developed countries, 3.3 percent in the central plan countries, and 2.1 percent in the developed countries.

During 1955-57 through 1963-65, world demand also increased at 3.1 percent a year. But in the developed countries, demand grew 3.2 percent annually, compared with 3.0 percent in the central plan countries and 3.2 percent in the LDC's. Thus, while the rate of increase in world demand is the same for the historical and projected periods, a lessening in the rate of increase is projected for the developed countries and a higher rate of increase is expected in the LDC's and the central plan countries.

Table 16.--Summary of regression analysis of regional per capita consumption of vegetable oils

Region	Time period	Durbin-Watson statistic	R^2	F-value	$\bar{S}$	Function	Multiple regression 1/

PART III.--WORLD DEMAND FOR OILCAKES

The oilcakes to which this report gives primary attention are soybean, peanut, cottonseed, rapeseed, linseed, sunflowerseed, copra, and palm kernel.

For purposes of analyzing the world market for such oilcakes, nine of the 18 regions used in the vegetable oil demand analysis were aggregated into four regions. This was done because individually the nine regions were relatively unimportant markets for oilcakes. Of the developed countries, Australia and New Zealand were combined with South Africa to form one region. Of the less developed countries, Central America was combined with South America to form a Latin American region; the North Africa and West Asia region was combined with the East and West Africa region to form an Africa and West Asia region; and the South Asia, Southeast Asia, and East Asia and Pacific Islands regions were combined to form "Other Asia." No changes were made in the regional classifications of the central plan countries.

Oilcakes are principally used as protein supplements to livestock feed, and are consumed primarily in the industrially advanced regions of the world, where there is a high effective demand for meat, milk, and eggs. In the less developed countries, where a substantial proportion of the world's supply of oilcakes is produced, most of the meal is exported rather than used as livestock feed within the country.

In addition to their use in feed, some oilcakes are used directly as human food and others used as fertilizer. Direct human consumption is restricted to relatively small quantities of peanuts and soybeans. Research is being done to increase the direct utilization of oilcakes in human consumption, but little has been accomplished so far. Significant successes in the research could drastically alter the pattern of world trade. Use of oilcakes for fertilizer is very limited and is restricted to certain areas and to certain meals, principally rapeseed meal because of its low palatability.

With respect to the use of oilcakes in livestock feeding, animal feeds may be considered as consisting of roughages and concentrates. Roughages, such as hay and silage, are consumed primarily by ruminants. Concentrates consist of low- and high-protein concentrates. The low-protein concentrates provide a concentrated source of energy and consist primarily of feedgrains. Oilcakes are the major component of high-protein concentrates. Products competing with oilcakes include fishmeal, tankage, skim milk powder, brewer grains, dried blood, and synthetics such as urea. Urea is suitable for ruminant feed only; in contrast, the other products are fed primarily to nonruminants. The main oilcake-competing product traded is fishmeal and in the 1956-65 review of trade, production, and consumption, attention is given only to this product. In the demand analysis of the major consuming regions, consideration is also given to other competing products.

Oilcake utilization is directly related to the growth of the compound feed industry. Only in the past few decades have farmers come to realize that feeding a balanced compound feed can raise a beef cow to 1,000 pounds in 18 months and a broiler to 3 pounds in 7 weeks. Thus, to meet a strong demand for meat products, the compound feed industry in most developed countries has expanded sharply and oilcakes have served as the principal protein concentrate. Appendix C discusses the uses of the various oilcakes.

For the analysis of oilcake demand, trade and production statistics were obtained by commodity and region from 1955 to 1966 for trade and to 1968 for production. For presentation purposes, changes are made in averages for 1955-57 and 1963-65. The period 1963-65 was selected because it coincides with the 3-year average used in the tables presenting changes in vegetable oil trade, supply, and demand. As indicated in the section on vegetable oil, complete 1966 trade data on vegetable oil were not available for some of the less developed countries. Thus, for the sake of consistency, changes in all regions were presented on a 1963-65 basis.

7.--INTERNATIONAL TRADE IN OILCAKES

Level of Trade

World imports of oilcakes, meal-equivalent basis, averaged 15.6 million tons during 1963-65 (table 21). This was an annual increase of 7.5 percent over the 1955-57 level of 8.8 million tons. Of the 6.88 million-ton net increase in total oilcake imports, the developed regions accounted for 78 percent and the less developed regions, for some 17 percent. The central plan countries showed only a very moderate increase over the period.

In terms of oilcake exports, those from the central plan regions declined during 1955-57 through 1963-65 by 5.4 percent annually, while exports from the developed countries increased by 12.1 percent a year. LDC exports increased by 8.6 percent a year.

Soybean meal comprised 54 percent of total 1966 trade in oilcakes (table 22). Peanut meal and cottonseed meal were next in importance, accounting for 12 and 9 percent of the total, respectively. Compared with 1960-64 average levels, 1966 soybean meal exports increased 8 percent, but peanut meal decreased 5 percent and cottonseed meal, 1 percent. Soybean meal has increased its market share. Soybeans, relative to other oilseeds, have a high meal-to-oil ratio, and since the market for meal has been growing much faster than the market for oil, developed importing countries prefer soybeans to other oilseeds. Large quantities and consistent quality of soybeans and soybean meal have always been available, so large cargo vessels can be used and the products can be bulk loaded. The quality of the oilcake makes it particularly well suited for feed for poultry.

Meal, as such, comprised 45 percent of total world oilcake trade in 1966, compared with 42 percent during 1960-64. Conversely, meal trade in the form of oilseeds was 55 percent of the 1966 total oilcake trade and 58 percent of the 1960-64 trade.

Importance of Trading Regions

Exporting Regions

During 1955-57, the less developed countries accounted for approximately 51 percent of world oilcake exports. The developed countries accounted for approximately 36 percent, and the central plan countries made up the remaining 13 percent. By 1963-65, the developed countries had increased their share of the export market to 52 percent, with most of the increase coming at the expense of the central plan countries. Annual percentage growth rates during 1955-57 through 1963-65 were 12.1 for the developed countries and 4.9 for the LDC's. A negative rate of change for the central plan countries was due to a large drop in exports from the Communist Asia region.

Rankings among the individual regions were altered only slightly during the review period. During 1955-57, the top four exporters of oilcakes were, in descending order, the United States, Other Asia, Africa and West Asia, and Communist Asia. During 1963-65, the only change was that Latin America replaced Communist Asia in fourth place.

Importing Regions

During 1955-57 through 1963-65, considerable change occurred in the relative importance of regions that imported meal. The top five regions in order of importance during 1955-57 were the EC, the United Kingdom, the Other Western European countries, Japan, and Canada. By 1963-65, the O.W.E. region had replaced the United Kingdom in second place. Japan had moved to third place, the United Kingdom had dropped to fourth place, and Eastern Europe had replaced Canada in fifth place.

On a percentage basis, the developed countries accounted for 77 percent of total world imports during 1963-65, while the central plan countries accounted for 7 percent and the LDC's for 16 percent. The annual growth rate in imports for the developed regions during 1955-57 through 1963-65 was 7.6 percent, compared with 4.0 percent for the central plan countries and 8.6 percent for the LDC's.

Changes in Trade Levels

Net Exporting Regions

On a net exporting basis, rather than a gross exporting basis, the United States ranked first in 1955-57 in oilcake exports, with net exports of over 2.0 million tons. The Africa and West Asia region ranked second with 1.5 million tons, Other Asia third with 1.0 million tons, Communist Asia fourth with 0.7 million tons, and Latin America fifth with 0.7 million tons.

In 1963-65, the United States, with net exports of 6.9 million tons, was still the largest net exporter, while Africa and West Asia, with average net exports of 2.0 million tons, retained second place. Latin America, with net exports of 1.4 million tons, climbed to third place. Fourth and fifth place were occupied by Other Asia and the USSR, respectively.

Total net oilcake exports for 1955-57 were 6 million tons. Of this, the United States accounted for 33 percent, Africa and West Asia for 25 percent, Other Asia for 16 percent, and Communist Asia for 15 percent. By 1963-65, total net exports had grown to 11.1 million tons. The United States accounted for 62 percent of the total, Africa and West Asia accounted for 18 percent, and Latin America for 13 percent. The remaining four exporting regions accounted for 7 percent of the total.

Net Importing Regions

Changes in the rankings of the net importing regions followed the same general pattern as changes in the ranking of the net exporting regions; that is, there was no change in the top position but considerable change thereafter. Thus, the EC, with 2.1 million tons of net imports in 1955-57 and 5.0 million tons in 1963-65, was the largest net importer at both the start and end of the period. In 1955-57, the United Kingdom, with 1.4 million tons, held second place; the O.W.E. region was in third place; Japan in fourth; and the USSR, with imports of just over 0.4 million tons, was in fifth place. In 1963-65, the O.W.E. region ranked second and Japan ranked third. The United Kingdom, with 1.6 million tons of imports, had slipped to fourth place and Eastern Europe had moved to fifth place. The former fifth place country, the USSR, changed from a net importer to a net exporter during 1963-65.

Annual growth rates for the net importers varied from a high of 18 percent for the Eastern Europe region to a low of 1.1 percent for the United Kingdom. Net imports for the EC increased 11.7 percent annually. For Japan, the rate was 11.8 percent and for the O.W.E. region, 8.9 percent.

Total net oilcake imports for 1955-57 were 6.1 million tons, of which the EC accounted for 34 percent; the United Kingdom, 23 percent; the Other Western Europe region, 18 percent; Japan, 12 percent; and the USSR, 7 percent. In 1963-65, net oilcake imports totaled 11.4 million tons. The EC accounted for nearly 44 percent of that total. Second place was occupied by Other Western Europe, with 19 percent of the total, and third place was held by Japan, with 16 percent of the total. Thus 79 percent of total net oilcake imports was taken by the three top regions.

Trade in Substitutes

Although a variety of products compete with oilcakes as a protein supplement, fishmeal is the main competitive product exchanged through international trade. Fishmeal imports increased from an average of 0.5 million tons in 1955-57 to an average of 2.1 million tons in 1963-65--an average annual increase of 17.1 percent (table 23). The developed regions accounted for 85 percent of 1963-65 imports, while the central plan regions accounted for 10 percent. The largest importers by region in 1963-65 were the EC, the United Kingdom, and the United States. The EC alone accounted for over a third of all fishmeal imports.

Six countries--Peru, Norway, South Africa, Iceland, Chile, and Denmark-- provide approximately 93 percent of the world's exports of fishmeal. Peru is easily the world's leading exporter (table 24).

Table 21.--World trade in oilcakes, including meal equivalent of oilseeds traded, by region, averages for 1955-57 and 1963-65, and annual rates of change

8.--PRODUCTION OF OILCAKES

Production of Parent Materials

World oilseed production was discussed on pages 31-39 in chapter IV of this report. Regional production levels are shown in appendix tables B-1 - B-26. These tables show that 1955-68 production increases were greatest for soybeans and sunflowseed. The lowest rates of increase were for palm kernels, copra, and cottonseed, all of which are grown primarily in the less developed countries.

Procedure for Computing Oilcake Production

Oilcake production estimates were obtained by first applying the crushing levels contained in appendix B to the estimates of oilseed production in each country. The levels used varied between crops and between countries.

Once estimates of the quantity of each oilseed crushed were obtained, that quantity was converted to a meal-equivalent basis by application of the meal yield factors shown in appendix B. The meal equivalent of each oilseed in each region was allocated to the calendar year during which the crop's processing chiefly occurred. The meal equivalent was credited to the country where the seed was grown rather than to the country where the crushing actually took place.

World Production

World oilcake production increased from an average of 28.2 million tons in 1955-57 to an average of over 41.5 million tons in 1965-67 (table 25). The difference, over 13 million tons, represents nearly a 50-percent increase over the period, or a 4.0 percent annual growth rate.

During 1960-62 through 1965-67, world production increased nearly 8 million tons--a 24-percent increase, or an annual increase of 4.4 percent. The central plan region had a sharp increase in its annual growth rate, while the developed and less developed areas showed moderate declines.

Regional Production

On a regional basis during 1955-57 through 1965-67, oilcake production increased 5.9 percent annually in the developed regions, 1.2 percent in the central plan regions, and 3.2 percent in the less developed regions. The developed countries, whose rate of increase was more than double that of the rest of the world, increased their share of world production from 43 to 52 percent. Seven of those nine percentage points came from the central plan countries, while the remaining two points came from the LDC's.

The United States accounted for 48 percent of 1965-67 world oilcake production. Other Asia and the USSR ranked second and third, respectively, with 12 and 11 percent of the total. During 1955-57, the top three producing regions were the United States, Communist Asia, and Other Asia.

During 1955-57 through 1965-67, only Japan and South Africa among the developed countries had annual growth rates below the 4.0-percent world average. In the central plan region, Communist Asia and the USSR had growth rates smaller than the world average. Among the less developed countries, Latin America was the only region whose growth rate surpassed the world average. Japan and Communist Asia were the only regions to have lower production at the end of the period. The United Kingdom was the only region producing no significant quantities of meal.

Production of Fishmeal

Fishmeal production increased 12 percent annually during 1955-57 through 1963-65 (table 26), compared with a 4-percent rate of increase for all oilcakes. World fishmeal production averaged approximately 3.4 million tons in 1963-65, while total oilseed meal production averaged some 42 million tons. Thus, fishmeal production during 1963-65 was approaching 8 percent of total oilcake production.

During 1955-57 through 1963-65, production ranking changed considerably. In 1955-57, the United States was the leading fishmeal producer, Norway was second, and Japan was third. In 1963-65, Peru had moved into first place and was producing more than four times as much as the United States, which had moved to second place. Japan and South Africa maintained their relative positions, ranking third and fourth, respectively, while Norway dropped to fifth place.

Table 25.--Oilcake production, by region, averages for 1955-57, 1960-62, and 1965-67, and annual rates of change

Region	1955-57 average	1960-62 average	1965-67 average	Share of total		Annual rates of change

9.--CONSUMPTION OF OILCAKES

Regional estimates of oilcake consumption were developed from 1955 to as far as data permitted. Except for the United States, such estimates were the sum of a region's production and net trade. The United States was the only region for which a usable series of actual oilcake consumption data was available.

During 1955-57 through 1963-65, world oilcake consumption expanded at an average annual rate of 4.3 percent, or from an average of 28.2 to 39.5 million tons. The developed countries maintained the largest annual growth rate, 5.7 percent, with the result that they accounted for 62 percent of total consumption by 1963-65. As a group, the less developed countries had an annual growth rate of 3.5 percent; and in 1963-65, their annual level of oilseed meal consumption was 6.2 million tons. For the central plan region, the annual growth rate was 1.4 percent and annual consumption was 8.7 million tons.

During 1963-65, the United States, using 12.3 million tons of oilcakes, accounted for 32 percent of total world consumption. The EC was the second largest consuming region, 5.2 million tons, followed by Other Asia, 4.3 million tons, and the USSR, 3.8 million tons.

The EC, with an annual increase of 11.5 percent, had the highest consumption growth rate of any region. Japan was second, at 9.5 percent. The Other Western Europe region at 8.8 percent, was third; the Eastern Europe region, at 7.3 percent, was fourth; and Other Asia, at 4.9 percent, was fifth.

The major consuming region, the United States, had a growth rate lower than that of a number of other regions--primarily because the U. S. level of concentrate feeding per animal unit is quite high. Since the early 1960's, the increase in demand for oilcakes in the United States has moved in line with the increase in total livestock numbers. In the regions of the world where demand has been increasing the fastest, there has been an increase in the number of livestock fed plus a heavier feeding of concentrates per animal unit.

Regional Use of Individual Oilcakes

The type of oilcake consumed within an exporting region is largely determined by the type of oilcake produced within that region. The types of meal consumed within an importing region are, as one would expect, more varied. Some countries have preferences for particular types of cakes; for example, in the Netherlands, linseed meal is preferred in most compound feeds. But in general, the cake utilized is the one that can meet the required nutritional levels at the lowest price. A wide variety of cakes can be used for cattle feed because of the ability of ruminants to convert nitrogenous matter to amino acids. For poultry and swine feeds, the fiber content, the amino acid pattern, the toxicity, and the vitamin and mineral content all have a strong bearing on the type of cake selected. The variables to be considered to arrive at the most economical and nutritive feed formula are so many that more and more compound feed manufacturers are utilizing a computer.

Shifts in the kinds of cakes being consumed in the major markets are most important to regions that export, in quantity, only one or two types of cakes. For this reason, a short discussion follows regarding the types of cakes plus fishmeal consumed in the six major developed regions of the world during 1955-57 and 1963-65.

United States

In both 1963-65 and 1955-57, soybean meal accounted for over three-fourths of total U. S. meal consumption (table 28). Cottonseed meal was the second most important meal consumed. In 1963-65, fishmeal ranked third. Linseed meal ranked third in 1955-57.

During the review period, peanut meal had the largest annual rate of increase--13.3 percent. Fishmeal increased 6.9 percent annually and soybean meal, 4.7 percent. The comparable rate for cottonseed meal was 2 percent, while fourth-ranked linseed meal exhibited a negative trend.

Canada

Oilcake consumption in Canada was comprised principally of linseed meal and soybean meal during 1955-57. By 1963-65, soybean meal was in first place and linseed meal in second. The largest annual rate of increase, however, was in the consumption of rapeseed--12.8 percent. This rate was more than two times the overall meal consumption rate of increase and was approximately double the rate of increase for both soybean meal and fishmeal.

EC

Soybean meal is the dominant meal consumed in the EC, where nearly 2.4 million tons were consumed annually during 1963-65. Soybean meal consumption increased 20 percent annually from 1955-57 to 1963-65. Fishmeal consumption, with an annual rate of increase only slightly below 30 percent, ranked second in terms of quantity. Third place was held by linseed meal--annual consumption averaged three-quarters of a million tons during 1963-65. Peanut meal consumption, which ranked fourth, was only slightly less than linseed meal consumption, and had a faster rate of growth than linseed meal during the review period.

O.W.E.

Soybean meal was also the major meal consumed in this region during 1963-65. Cottonseed meal, ranked second in terms of quantity, did not rank among the top five meals in annual growth rates. Fishmeal ranked third in both annual growth rate and quantity of consumption. Peanut meal, though it ranked fourth in quantity consumed, ranked second behind soybean meal in annual growth rate.

United Kingdom

Consumption of peanut meal, the principal meal utilized in the United Kingdom, averaged 600,000 tons during 1963-65. Soybean meal consumption, nearly one-half million tons, ranked second and fishmeal consumption ranked a close third. Fishmeal had the highest annual growth rate during 1955-57 through 1963-65--13 percent. Soybean meal, at 6.5 percent, and peanut meal, at 5.8 percent, were second and third, respectively. Most of the other meals had negative rates of change; consequently, growth of the U. K. meal industry was just over 3 percent a year during 1955-57 through 1963-65 period.

Japan

In Japan, meal consumption centers on soybean meal, which accounts for three-fourths of all oilcake consumption. Soybean meal consumption averaged 1.4 million tons in 1963-65. Fishmeal was in second place, with consumption at less than 0.4 million tons. Consumption of all other oilcakes averaged 0.3 million tons in 1963-65. From 1955-57 through 1963-65, consumption of fishmeal and soybean meal had annual growth rates of 14.6 and 9.0 percent, respectively.

Consumption of Fishmeal

As shown in table 28, world consumption of fishmeal has been increasing at a rate more than three times that for oilcakes. Nearly all of the increase occurred in the developed regions. The main reason for the rapid growth of fishmeal consumption has been its low cost relative to that of oilcakes as a source of protein. Fishmeal is consumed primarily in poultry rations, where it can constitute up to 10 percent of the mixed feed ration.

10.--DEMAND ANALYSIS AND PROJECTIONS FOR OILCAKES 13/

Analysis

The establishment and development of commercial livestock feeding enterprises is highly correlated with the level of overall economic development in a region. In the most less developed regions, livestock enterprises tend to be of a subsistence nature. Frequently, the livestock depend on what feed they can forage for themselves.

In those developed regions where livestock feeding has developed into a highly complex industry, livestock are fed scientifically formulated balanced rations that contain the necessary quantities and proportions of amino acids, vitamins, minerals, heat and energy, and bulk. Because different animal species, and even the same animals at different stages of growth, require different feed formulations, mixed feed industries have developed for the purpose of producing concentrate feed rations to meet the exacting nutrient requirements of the various types and ages of livestock. In the economically advanced regions that have highly developed commercial livestock feeding industries, the major portion of world consumption of oilseed meals occurs.

Livestock feeding enterprises based on formula feeding of premixed concentrate feeds are largely limited to Western Europe, North America, and Japan. In 1965, nearly 95 percent of world production of mixed feeds was produced in these regions. The United States alone produced 52 percent of the world total in 1965 and 68 percent in 1957. Western Europe produced 37 percent of the total in 1965, while Japan produced 7 percent; these two figures compare with 28 percent and 2 percent, respectively, for 1957 (10, vol. IV, ch. VI). Although mixed feed output increased significantly in all the developed regions from 1957 to 1965, the very rapid increase in Western Europe and Japan caused the U.S. percentage of world output to decline.

World trade in mixed livestock feed is negligible--partly because feed specifications vary in different countries and regions. In addition, each consuming region will have some feed components available from domestic production, and will import additional ingredients to complement domestic production. It is advantageous for feed deficit regions to purchase feed ingredients on the world market and then formulate concentrate feeds to meet domestic requirements. Thus, the major trade in feedstuffs is in such ingredient commodities as oilseed meals, coarse grains, and protein supplements from such sources as fishmeal and milling byproducts.

Because of the interrelationship between oilseed meals and feed grains in the advanced livestock feeding regions, an analytical model that jointly considered the demand relationships for both of these major mixed feed ingredients was developed. The model was designed to estimate regional demand relationships that could be used as the basis for projecting the regional demand for oilseed meals. Because of the dominance of the developed countries in oilseed meal consumption, the following analysis is limited to the major consumers--Western Europe, North America, and Japan. The demand for oilseed meals in the remaining regions is analyzed separately under a different model.

The Model, Major Developed Regions

A two-stage least squares regression model was used to analyze the demand for oilseed meal in the major consuming regions of Western Europe (the EC, the United

13/ The analysis and projections of demand for oilcakes in the major developed regions was prepared by Donn R. Reimund, Marketing Economics Division, Econ. Res. Serv., U.S. Dept. of Agr.

Kingdom, and O.W.E.), North America (the United States and Canada), and Japan. The model consists of two behavioral equations for oilseed meal demand and for feed grain demand: One, an identity equation that specifies concentrate feed consumption as the sum of feed grain, oilseed meal, and other high-protein meal consumption; and the other, an identity establishing supply-demand equilibrium. The model is given in equations a through d.

(a) Oilseed meal demand $Q_m = f(p_m, p_g, Q_{os}, L^p_{t-1})$

(b) Feed grain demand $Q_g = f(p_m, p_g, L^p_{t-1})$

(c) Total mixed feed consumption $q^d_t = Q_m + Q_g + Q_{os}$

(d) Supply-demand equilibrium $Q^d_t = Q^s_t$

Where:

Q_m = consumption of oilseed meal (endogenous)

p_m = import price of soybean meal (endogenous)

p_g = domestic price of feed grain (endogenous)

Q_{os} = consumption of other high-protein supplements (exogenous)

Q_g = consumption of feed grain (endogenous)

L^p_{t-1} = meat production in previous year (exogenous)

Q^d_t = consumption of total concentrate feed (exogenous)

Q^s_t = supply of concentrate feed (exogenous)

All quantity variables are in metric tons per 1,000 population and price variables are expressed in U.S. dollars per metric ton.

The model contains no provision for stock variation in either oilseed meals or feed grains. It is implicitly assumed that stocks in net importing regions consist primarily of working inventories and consequently are relatively stable and quite small in comparison with consumption.

The demand equation for oilseed meal expresses consumption as a function of oilseed meal price, feed grain price, the quantity of other high-protein concentrates consumed, and the production of meat lagged 1 year. The feed grain demand equation expresses consumption as a function of the prices of oilseed meal and feed grain and the lagged production of meat.

The exogenous variable Q_{os}, which represents the consumption of nonoilseed protein feed supplements, requires some clarification. The variable is a heterogeneous composite that includes fishmeal, meat meal and tankage, milling byproducts, and urea. Its composition varies considerably from region to region and, to some extent, over time within each region. The variable was treated as exogenous primarily because its components, with the exception of urea, are produced either entirely or in part as byproducts of other industries. Its availability, therefore, is largely determined by the level of output of the primary products of the meat slaughtering, milling, and edible fish industries. Only a small part of the fishmeal consumed as livestock feed, however, is produced as a byproduct from edible fish.

Meat production, which includes poultry meat, was considered to be a better explanatory variable than either animal units or total production of livestock products. It appears logical to assume that consumption of feed concentrates is more closely associated with output of livestock products than with the total animal population in a region. Meat production was favored over the total production of livestock products because the per capita output of eggs and dairy products is quite stable. Thus, the growth in output of livestock products is primarily attributable to the growth in meat production. Consequently, the variability of oilseed meal consumed by livestock is considered to be a direct response to per capita variations in meat production. The meat production variable used in the model was lagged 1 year because preliminary analysis showed a better correlation between lagged meat production and meal consumption than between current meat production and meal consumption. This is probably because the requirements for oilseed meal are determined in advance of consumption, and are based on per capita production of livestock products of the previous year.

The consumption series for oilseed meals in all regions except the United States was constructed by adding net meal imports and the meal equivalent of net seed imports to the meal equivalent of domestic seed production. For the United States, actual consumption figures were used. Trade data were compiled from various issues of the FAO Trade Yearbook. Production data are from the FAS and the FAO. For the analysis of oilseed meal demand, all meal consumption data were converted to metric tons per 1,000 population.

For all regions other than the United States, the consumption series for feed grains was compiled from OECD food balance statistics. Actual consumption was used for the United States. The consumption series for other high-protein feed supplements was constructed from FAO and FAS data, and the meat production series was compiled from the OECD data. Like the oilseed meal consumption data, consumption data for feed grains and other high-protein supplements and production data for meat were converted to metric tons per 1,000 population.

Soybean meal price was used to represent the price of oilseed meals in the demand analysis. The primary reason for using soybean meal price rather than a weighted average meal price was the dominance of soybean meal as a high-protein feed supplement. In addition, there is a high correlation between the price of soybean meal and the prices of other oilseed meals. Consequently, a weighted average oilseed meal price would closely approximate the price of soybean meal.

London prices, as quoted in the Daily Ledger, were used to represent the price of soybean meal in the three European regions and Japan. U. S. prices were used for the United States and Canada. The prices were deflated by an appropriate price index; and in the case of the EC and O.W.E. regions, by the price index of a major importing country within the region. These indexes are as follows:

EC	-	cost of living index (France)
United Kingdom	-	cost of living index
Japan	-	cost of living index
O.W.E.	-	cost of living index (Denmark)
United States	-	cost of feedstuffs index
Canada	-	wholesale price index

Feed grain prices were represented by the internal price of a major domestically produced feed grain. The price of barley was used for all regions except the United States, for which corn prices were used. Wholesale prices were used in most cases. However, when adequate wholesale price series were not available, producer prices were used. Feed grain prices were deflated by the same deflators as were soybean meal prices.

The parameters of the structural demand equations for oilseed meal were estimated using a two-stage least squares procedure.[14] In this procedure, the endogenous explanatory variables in any structural equation are adjusted for correlation with the disturbance term by regressing each endogenous variable on all exogenous variables in the system. The adjusted endogenous explanatory variables are then substituted into the structural equation in place of the original variables and least squares is applied to the adjusted equation. This procedure makes use of all the predetermined exogenous variables in the model to estimate the parameters of a single structural relation, but does not require a detailed specification of the other relations in the model. The demand equations derived from the above model for each region are:

EC: $Q_m = -151.5578 - .6603\ p_m + 2.0731\ p_g + .2164\ Q_{os} + 1.7570\ L^p_{t-1}$

U.K.: $Q_m = 325.4974 - 1.2980\ p_m - 1.5072\ p_g + .4926\ Q_{os} - 1.7246\ L^p_{t-1}$

O.W.E.: $Q_m = 345.2654 + 4.6625\ p_m - 9.7326\ p_g + 1.6066\ Q_{os} - 3.8104\ L^p_{t-1}$

Japan: $Q_m = 19.1063 - .0844\ p_m - .0684\ p_g + .3832\ Q_{os} + 1.4984\ L^p_{t-1}$

U.S. [15]: $Q_m = 140.2853 + .4671\ p_m - 1.0823\ p_g - 1.0710\ Q_{os}$

Canada [15]: $Q_m = 111.5534 + 1215\ p_m - 1.073\ p_g + .1293\ Q_{os}$

In the six regions analyzed, the demand for oilcake is related to the demand for feed grains since both are inputs to the same enterprise--the livestock industry. In some areas, the relationship between feed grains and oilseed meal is predominantly complementary, while in others it might be competitive. Results from the analysis of the EC indicated that the relationships between feed grains and oilseed meal were competitive because of the high price of grains relative to meal prices. But in the other five regions, the results indicated that a complementary relationship existed. The direct price coefficients for Other Western Europe, the United States, and Canada were positive rather than negative.[16] This result is apparently caused by the interrelationship between oilseed meals and feed grains in the manufacture of mixed feeds in these regions. These ingredients are combined in rather stable proportions, with no significant competitive relationship existing between them. The price of feed grains, the major ingredient in mixed feeds, thus appears to have more influence than

---

[14] A description of the two-stage least squares estimating procedure is given in (38, pp. 258-260).

[15] L^p_{t-1} was taken out of these equations because of intercorrelation problems

[16] The results obtained in this analysis differ from those obtained by other analysts. For example, Houck (32) in a model taking into account the complex interrelationships of the U.S. oilseeds economy, estimated a demand price elasticity of -0.33 for soybean meal, compared with -0.28 estimated by Vandenborne (68) in another study. These studies, however, did not consider the cross price relationships between feed grains and oilseed meals.

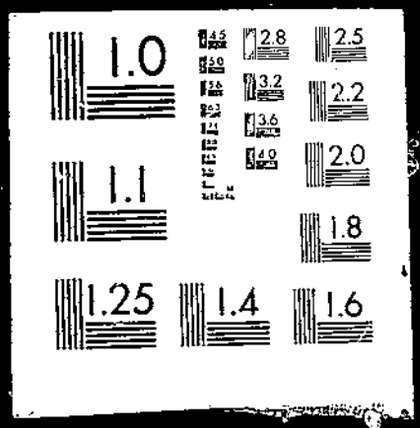
WORLD SUPPLY AND DEMAND PROSPECTS FOR OILSEEDS AND OILSEED PRODUCTS IN 1980 WITH EMPHASIS ON TRADE BY THE LESS DEVELOPED COUNTRIES. (Foreign Agricultural Economic Report). /_Lyle E. Moe (and others). Washington, DC: Economic Research Service, Mar. 1971. (NAL Call No. A281.9/Ag8F)



the price of meal in determining the level of oilseed meal use. For the United Kingdom and Japan, the oilseed meal price coefficient carried the expected negative sign.

The United States was the only region in which nonoilseed protein supplements appeared to substitute for oilseed meals. In the remaining five regions, a competitive relationship between protein feed supplements from oilseed and nonoilseed sources was not statistically apparent during 1955-66. The coefficients obtained for the nonoilseed protein supplement, in fact, indicate a complementary relationship between protein supplements from oilseed and nonoilseed sources. This phenomenon can largely be accounted for by the fact that pork and poultry products made up about 40 percent of the increase in output of livestock products in importing regions during 1955-66 (21, par. 615). Formula rations for these livestock call for the use of both oilseed meal and protein supplements of animal origin.

Lagged meat production was included as an explanatory variable in the oilseed meal demand equations for the United Kingdom, O.W.E., the EC, and Japan. The variable was excluded from the meal demand equations for the United States and Canada because it resulted in poor estimating equations. The meat production coefficients obtained were positive, as expected, for the EC and Japan, but were negative for the United Kingdom and O.W.E. This negative relationship is probably due to the fact that throughout the analytical period, oilseed meals became more expensive relative to livestock products in the United Kingdom and in Denmark, a major O.W.E. producer of livestock products (22, pars. 620-622). It is unlikely that this situation will hold in the future. Therefore, the estimated demand equations for the United Kingdom and O.W.E. were not used for projection purposes.

Estimated versus actual consumption of oilseed meals in each of the six regions during 1955-66 is shown in figure 3.

The Model, Other Regions

It is widely recognized that there is not an intensive use of oilcakes as an animal protein supplement in the less developed countries and Communist Asia. Also, use of oilcakes in Australia-New Zealand and South Africa is quite low, on an animal unit basis, compared with levels of utilization in the other developed regions. Use of oilcakes in Russia and Eastern Europe has been increasing but the levels of utilization, on an animal unit basis, are also considerably below those of the major developed regions. For regions other than the major developed regions, there is little or no interrelationship between oilseed meals and feed grains; thus, least squares estimates of a single equation, rather than two-stage least squares, were used for estimating future demand for oilcakes.

The aggregate demand for oilcakes depends on various factors including oilcake prices, total number of animal consuming units, availability of other protein products, level of income, and factors that affect demand over time, such as changes in feeding practices. Thus:

Figure 3

$$Q^{d}_{m} = f(A^{u}, p_{m}, Q^{gr}_{prod}, I, T)$$

Where:

Q^{d}_{m} = quantity of oilcakes demanded

A^{u} = animal units

p_{m} = price of commodity

Q^{gr}_{prod} = quantity of grain produced

I = income

T = trend

Several regression equations incorporating the above variables were developed for each of the seven regions considered in the "other regions" demand analysis. The regions are: (1) South Africa and Australia-New Zealand; (2) Eastern Europe; (3) the USSR; (4) Communist Asia; (5) Latin America; (6) Africa and West Asia; and (7) Other Asia. The dependent variable in the analysis, total consumption of oilcake, was the sum of a region's production and its net trade. For the independent variables, the animal numbers as contained in (37) and the FAO Production Yearbooks were converted into animal units. 17/ The amount of oats, barley, and corn produced in a region was used for the quantity of substitutes. The international price of the major oilcake traded by the region was used for the price of the commodity. In some regions, the production of meal ($Q^{m}prod$) was used in place of the price variable. With respect to income, the historical series used were those contained in (44). While a trend factor was considered in some of the equations, it was not used in any equation containing income because of the intercorrelation problem posed.

The various demand equations developed for each region appear in table 29. The linear function was used in all regression equations, and the time period was 1955-66. Evaluation regarding the appropriateness of each equation with respect to statistical considerations was the same as that stated in the demand analysis section for vegetable oil.

The functions developed and selected for the respective regions are discussed briefly in the following section on regional projections.

Projections

Major Developed Regions

The preceding regional demand analyses were used as the basis for projecting consumption of oilseed meals for 1980. In the projections, oilseed meal and feed grain prices are held constant at their 1963-65 average. Meat production was estimated as the mean of OECD meat production projections for 1975 and 1985 (47).

17/ Factors used for converting livestock numbers to animal units appear in (10, vol. 5, p.2).

The 1980 consumption of other high-protein supplements, the other exogenous variable in the oilseed meal demand equations, was estimated by a linear trend extrapolation for all major developed regions except the United States. For the United States, a semi-log projection of trend was used to estimate 1980 consumption.

Several factors influence the underlying structure of the other high-protein supplement variable. First, the rapid growth in fishmeal, which contributed significantly to the growth in other high-protein supplements during 1955-66, is expected to taper off. Secondly, a major growth in synthetic protein supplements that may be produced from either petroleum or natural gas is anticipated in Western Europe and Japan. Also, utilization of urea, which in the past has been limited primarily to the United States, will probably increase in cattle feeding in other regions. The growth of the synthetic protein industry in the United States is expected to be considerably slower than in the importing regions of Europe and Japan, since the United States is a major producer and exporter of oilseed meals. Consequently, the growth in nonoilseed protein supplements is projected at a lower rate in the United States than in the other five developed regions.

Projections of oilseed meal demand for the six major developed areas are given in table 30. Because of the livestock products/oilseed meal price relationship that existed in the United Kingdom and other Western Europe region during 1955-66, the demand relationships developed for these two regions were not believed valid for projection purposes. Consequently, the EC demand relationship, which was felt to be a better reflection of expected future conditions in Western Europe, was used to project for the United Kingdom and the O.W.E. region.

In the United Kingdom, where the techniques of livestock and poultry feeding have reached a high level of sophistication, demand for oilcakes during 1960-67 was quite weak, mainly because oilcakes became more expensive relative to livestock products. This price relationship reversed itself in 1968 and, consequently, oilcake imports increased rather substantially. Price relationships of 1968 rather than 1963 were used for projections.

Other Regions

The projections developed for the seven regions in this group were based on the demand equations in table 29.

South Africa and Australia-New Zealand.--Of the three equations developed for this region, the one containing grain production and income was statistically significant at the 5-percent level and was considered the most reasonable for projection purposes. The equation with trend yielded an R^2 value of only .23, compared with .52 for the one selected, while the remaining equation had a wrong sign for the meal price coefficient. Relatively little feeding of oilcakes to livestock occurs in South Africa and Australia-New Zealand. Demand, which averaged 119,000 tons during 1963-65, is projected to increase 3.8 percent annually, reaching 215,000 tons by 1980.

Eastern Europe.--Four equations were developed for the Eastern Europe region; all yielded relatively good statistical fits. The equation using animal units, grain production, and oilcake production as independent variables yielded an R^2 value of .97 (table 29). This equation, however, would be better for making shortrun rather than longrun demand estimates because of the difficulty in estimating the future quantity or levels of the independent variables. For this reason, the equation using trend, which was statistically significant at the 5-percent level, and which had an R^2 value of .84, was used for estimating the 1980 demand. Projected demand for oilcakes in Eastern Europe by 1980 is 3.0 million tons, an annual increase of 4.0 percent from the 1963-65 average consumption level (table 30).

Eastern Europe is approximately in the same position that Western Europe was a decade ago with respect to consumption of animal products. Meat production has been steadily increasing and improved feeding techniques in the form of compound feeds are being increasingly adopted. If economic policies are not changed to restrict the production of animal products in the years ahead, the level of demand projected for the Eastern Europe region appears quite reasonable.

USSR.--For the USSR, five equations were developed. The three equations containing animal units as an independent variable provided good statistical fits, one with an R^2 value of 0.98; but in all cases, a negative sign resulted for the animal unit coefficient. This, of course, negated the use of these three equations for predictive purposes.

An equation using time and an equation using meal production as the independent variable were also developed. The equation using the trend factor had an R^2 value of only 0.19. The equation with meal production had an R^2 value of 0.71 and was statistically significant at the 5-percent level; the value of its Durbin-Watson statistic, however, was only 0.9, indicating an autocorrelation problem. The latter equation indicates that Russia's meal consumption will approach 5.7 million tons by 1980. This estimate was considered to be too low.

Although Russia is a net meat importer, average per capita meat consumption levels in the country are still quite low compared with Western levels. Meat production in Russia is expected to increase steadily through 1980, as is the intensity of feeding. Production of mixed feeds has been growing rather sharply in recent years but is still probably less than 20 million tons. Also, in recent years oilcakes have comprised only around 9 percent of the mixed feed rations, compared with 20 percent in advanced Western countries. Such potentials for increased oilcake consumption are not, of course, reflected in demand equations based on historical data. In consideration of the above factors, 1980 oilcake demand was placed at 6.4 million tons, or 700,000 tons over the level obtained by using the meal production equation. This is an annual rate of increase of 3.8 percent over the 1963-65 average.

Communist Asia.--Meal production and trend were used as independent variables in the demand equations for Communist Asia. From a statistical point of view, meal production was the better explanatory variable. The equation with this variable indicates that demand by 1980 will approach 3.9 million tons. Since 1980, oilcake production for this region is estimated at 5.3 million tons, 1.4 million tons would be available for the export market. This is not a reasonable level of exports since meal exports during 1963-65 averaged 82,000 tons. It is estimated that in 1980 meal exports will be about 450,000 tons, which in turn, implies that domestic demand within the region would approach 4.8 million tons.

Latin America.--By 1980, oilcake consumption in Latin America is projected to approach 1.9 million tons, compared with a 1.1 million-ton average during 1963-65. The estimate was obtained by using an equation with income and the world price of soybean meal as explanatory variables. The income and price variables were statistically significant at the 5- and 10-percent levels, respectively. The equation resulted in a more reasonable estimate than the two alternative equations developed for this region.

As in other LDC's, the livestock population in Latin America is maintained primarily on pasture lands. If various Latin American countries move, as anticipated, toward the development of poultry and swine industries with more sophisticated techniques of animal feeding, the 1980 estimate of 1.9 should be reasonable.

Africa and West Asia.--Four equations were developed for the Africa and West Asia regions; the equation with price and income as independent variables was selected. The equation, which was statistically significant at the 5-percent level, indicates demand will approach 1.4 million tons by 1980. This represents an annual increase of 3.0 percent over the 1963-65 level and is approximately the same rate of increase maintained during 1955-57 through 1963-65.

Presently, Israel is the only country in this region that has an advanced feed compounding industry. But the demand for animal products in the region, as in the other less developed regions, is expected to increase substantially. The feeding of oilcakes, mainly to chickens, is expected to increase. The bulk of the increase is expected to occur in West Asia and North Africa.

Asia.--For Asia, an equation using world copra meal prices and trend as explanatory variables yielded an R^2 value of .90 and an "F" value of 39.8. The equation indicates that demand for oilcakes will reach 8.8 million tons by 1980, an annual increase of 4.6 percent over the 1963-65 level.

The large cattle population in Asia consumes primarily roughages. Poultry and swine production have been relatively small. Demand for meat and dairy products is expected to increase sharply in the region's growing urban centers, where future per capita income increases will be concentrated. To meet the demand, a number of countries have included in their economic development plans provisions for expanding meat and dairy production. Most of the expanded increase in oilcake consumption in the region is expected to go to poultry and swine. The countries with the greatest rate of increase will probably be Taiwan and South Korea. Substantial increased feeding of poultry is expected to occur in West Pakistan and Ceylon. A study by the Institute for Research in Agricultural Economics at the University of Tokyo goes into great detail regarding the oilcake situation in India (34). The study projects demand for oilcakes in India to increase 4.0 percent a year, or 740,000 tons, from 1969 to 1976.

World Demand

Total world oilseed meal demand projections for 1980 are summarized in table 30. The projections indicate that at constant 1963-65 price levels, the developed areas will account for about the same percentage of the world's oilseed meal consumption as in the 1963-65 base period. The LDC's are projected to increase their share from just under 16 percent of the world total in 1963-65 to 18 percent in 1980. The central plan countries' share is projected to drop from 22 to 21 percent.

Consumption in the developed regions is projected to increase 64 percent from 1963-65 through 1980, an average annual increase of 3.2 percent. This compares with a projected increase of 59 percent, or an annual growth rate of 3.0 percent, for the central plan countries; and with an increase of 92 percent, or an annual growth rate of 4.1 percent, for the LDC's. Total world consumption is projected to increase from 39.5 million tons in 1963-65 to 55.1 million tons in 1980. This represents an increase of 67 percent and an annual growth rate of 3.3 percent.

Within the developed regions, the largest percentage increase is projected for Japan. Japanese meal consumption, 1.9 million tons in 1963-65, is projected to reach 4.9 million tons by 1980, an increase of 157 percent, or an annual increase of 6 percent. Consumption in each of the three European regions will approximately double during 1963-65 through 1980. The lowest growth rate is projected for the United States, where meal consumption is projected to increase from 11.8 million tons in 1963-65 to 15.2 million tons in 1980, an increase of 24 percent. This is an annual growth rate of 1.6 percent. The U.S. share of total world consumption will decrease from 31 percent in 1963-65 to 23 percent in 1980.

Among the central plan countries, the annual growth rate for meal consumption in the USSR is projected to about equal the annual world growth rate of 3.3 percent. Consumption in the Eastern Europe region is projected to increase 86 percent during 1963-65 through 1980, from 1.6 million to 3.0 million tons, an annual growth rate of 4.0 percent. The projection for Communist Asia shows an increase from 3.3 million to 4.5 million tons. This represents an annual rate of increase of 1.9 percent, the lowest growth rate for any region except the United States.

For the less developed countries, the greatest growth in oilseed meal consumption is projected for the region comprised of South, Southeast, and East Asia, and the Pacific Islands. During 1963-65 through 1980, annual consumption is projected to increase 105 percent, from 4.3 million to 8.7 million tons. This annual growth rate of 4.6 percent is comparable to the growth rate projected for the three regions of Western Europe. Meal consumption in the following two less developed regions is projected to increase at about the same rate as total world consumption. Latin America's consumption is expected to increase from 1.1 million to 1.9 million tons, an annual growth rate of 3.2 percent. Consumption in Africa (excluding South Africa) and West Asia is projected to increase 3.0 percent annually, from 0.8 million to 1.3 million tons in 1980.

PART IV.--PROJECTED SUPPLY AND TRADE FOR OILSEEDS AND OILSEED PRODUCTS

11.--PRODUCTION PROJECTIONS

The degree of land, labor, capital, and management invested in increasing the production of a given commodity is determined primarily by the price producers expect to receive. Thus, one of the main procedures for influencing the production of agricultural products is through price support arrangements. Such supports also help stabilize producer incomes. The support prices of some of the major oils and oilseeds in certain countries are well above world prices, while in other countries, they are well below. To attempt to quantify the effects of these varying support prices would be a formidable task, especially since support prices, in some cases, are linked with production controls and in other cases, are financed by higher consumer prices. Also, changes in output are influenced by factors other than price; for example, by weather conditions, price changes in alternative crops, increased use of resources, and improvement in production techniques. Further compounding the difficulty of developing reasonable estimates of price elasticities of supply for oilseeds is the fact that oilseeds have joint product values that vary from commodity to commodity.

Even if price supply elasticities were available, their use for projecting oilseed production would be limited. Empirical data indicate that it is highly inaccurate to use the same elasticities for both increases and decreases in price (37, p. 42). This is especially true for tree crops such as olives and palms. For these crops, little disinvestment can be expected in response to declining prices. For annual crops, it is not unusual to find that a fall in price results in expanded production.

Because of these difficulties, this report makes no attempt to estimate the relationship between the price and supply of oilseeds. The oilseed production projections developed in this report were, in general, based on a trend analysis for the 14-year period 1955-68 for each oilseed in each region. For major commodities in regional production, a trend analysis for the 7-year period 1962-68 was also made.

The assumption underlining the projection of production by past trends is that the forces that influenced past movements in area and yield will continue to influence in the same direction and magnitude in the future. Therefore, the commodity trend extrapolations were modified for some regions and took into account expected changes in institutional and economic factors that affect the level of production. Also, oilseed production projections in FAO reports and individual country projection studies were carefully reviewed before a final regional production estimate was made.

Future production of the tree crops (oil palms and olive) depends primarily on the current number and age of trees and the replanting and rehabilitation levels that are expected to occur through 1977. While a trend analysis was made of the tree crops, the resulting projected production levels depended heavily on an analysis of the national targets and policies of the major producing countries.

The cottonseed production projections were based on the estimated levels of cotton production contained in a recent ERS report on world demand for cotton (43). For soybean production in the United States, a trend analysis of area and yield was made. Resulting projected soybean area was considered to be too high, especially in view of the 1968 reduction in the support price. Two reports by Houck and others of the University of Minnesota provided the framework for the U.S. soybean production level used in this report (31 and 32).

The equations regressing time on production for each oilseed produced in each region are contained in table 32. After the oilseed production estimates (table 33) were made, they were converted into oil and meal equivalents; that is, the percentage of the crop

crushed plus the percentage of oil yield and meal yield in each oilseed. Conversion factors were the same as those used for the historical demand and production analyses. The use of historical conversion factors for the 1980 production estimates may be questionable since these factors are almost certain to change to some degree by 1980. But, no basis could be found for projecting 1980 factors with confidence. Thus, the conversion factors represent some of the underlying assumptions that may be changed as a result of technological developments, new information, or new policies, and that may require the projections to be amended accordingly.

Vegetable Oils

World vegetable oil production is projected to increase from an average of 18.4 million tons in 1963-65 to 31.7 million tons by 1980, an annual increase of 3.5 percent (table 34). Production is projected to increase by 3.8 percent a year in the developed countries, 3.4 percent in the central plan countries, and 3.3 percent in the less developed countries. The regions with the fastest annual rates of increase on a percentage basis are projected to be Australia-New Zealand, 19.0 percent; Canada, 8.2 percent; South America, 5.1 percent; Eastern Europe, 5.1 percent; and North Africa and West Asia, 4.3 percent. The regions with the largest projected annual quantity increases are the United States, 3.8 million tons; East Asia and Pacific Islands, 1.7 million tons; USSR, 1.6 million tons; South Asia, 1.3 million tons; and South America, 1.0 million tons.

On a commodity basis, the greatest annual rates of increase are expected to be for rapeseed oil, 4.7 percent; soybean oil, 4.5 percent; palm oil, 4.3 percent; and sunflowerseed oil, 4.1 percent. Olive oil production is projected to increase 1.4 percent annually; palm kernel oil, 1.8 percent; cottonseed oil, 2.8 percent; and peanut oil, 3.4 percent. The vegetable oils with the greatest projected annual quantity increases are soybean, 3.8 million tons; sunflower, 2.2 million tons; peanut, 1.9 million tons; and cottonseed, 1.4 million tons. Rapeseed, palm, and coconut are all projected to increase by around 1.2 million tons.

Oilcakes

World oilcake production is projected to increase by an average annual rate of 3.4 percent during 1963-65 through 1980. For the developed countries, production is projected to increase by 3.6 percent annually, compared with 3.1 percent for the central plan countries and 3.3 percent for the LDC's (table 35). The regions with the fastest annual growth rates are projected to be the EC, 6.7 percent; Eastern Europe, 5.0 percent; Canada, 4.1 percent; South Africa and Australia-New Zealand, 3.6 percent; and the United States, 3.6 percent. On a quantity basis, the regions with the largest annual increases are projected to be the United States, 14.0 million tons; Other Asia, 3.7 million tons; the USSR, 2.5 million tons; Africa and West Asia, 2.0 million tons; and Latin America, 1.8 million tons.

The oilcakes ranked in order of rate of increase are: rapeseed, sunflowerseed, soybean, peanut, cottonseed, copra, palm kernel, and linseed. The four oilcakes with the greatest projected increase in quantity are soybean, 15.3 million tons; sunflowerseed, 3.2 million tons; cottonseed, 3.1 million tons; and peanut, 2.7 million tons. These four oilcakes accounted for 88 percent of the total projected increase, leaving 12 percent of the increase for the remaining four oilcakes. Soybean meal alone accounted for 56 percent of the total projected increase in oilcake production.

Competing Products

Although projections of animal fat and marine oil production are not developed in this report, an appraisal of the probable trends is necessary to evaluate the price pressures they may bring to bear on vegetable oils.

From 1955-57 through 1966-68, world butter production increased by 1.8 percent a year. FAO's report on commodity projections (14) projects butter production to increase 2.2 percent a year during 1961-63 through 1975. An OECD report (47) that makes a rather detailed analysis of the livestock economies of member countries projects butter fat production to increase by only 1.2 percent per year from 1961-63 through 1985. The OECD countries presently produce around 60 percent of the world's butter. The central plan region's major butter-producing country, Russia, presently has a butter surplus and is not expected to increase production above past trends. In view of this and the findings of the OECD report, it would appear that the rate of increase for world production through 1980 will not exceed the past rate of 1.8 percent a year.

World lard production from the mid-1950's through 1966-68 also increased at a rate of 1.8 percent a year. The above cited FAO study (14) projects lard production to increase by some 2 percent through 1975. The report on the OECD countries projects pork production in member countries to increase 2 percent a year through 1985. In view of the trend toward meat-type hogs, however, lard production would be expected to increase at a rate lower than this. It is noted that the FAS 1970 estimate of world lard production is below the production level of 1968 and above 1969's (66). As with butter, it appears that the rate of increase in lard production through 1980 will probably not exceed the past growth rate of 1.8 percent.

Total world whale oil production trended steadily downward during the period of review, 1955-57 through 1966-68. Fish oil, however, trended sharply upward. As a result, marine oils increased at an annual rate of 2.5 percent.

The decline in whale oil production is expected to continue through 1980, but at a lower rate than in the past. In 1969, because of declining whale numbers, the International Whaling Commission reduced the 1969-70 Antarctica season quota on blue whales by 15 percent, while the North Pacific Whaling Commission reduced the 1969 sperm whale quota by 10 percent from the 1968 level (65).

Fish oil production is not expected to attain its past rate of increase, a large part of which was due to the rapid development of Peru's fishmeal industry. However, Peru's Sea Institute has indicated that in 1967 and 1968, the catch of anchovy, the main fish caught by Peru's fishing fleet, was at a level that impaired the reproduction ability of the anchovy. It appears unlikely, therefore, that fish oil production through 1980 will exceed the past annual rate of increase of 2.5 percent.

Fishmeal and urea are major competitors of oilcake as a high-protein supplement to animal feedstuffs at present. The use of fishmeal has expanded greatly since 1955, primarily because of its high portion of protein and relatively low price in relation to oilcakes. But fishmeal production is not expected to continue in line with past trends. The big growth in production is primarily attributable to Peru. But Peru, according to its Sea Institute, has already attained a level of fishmeal production that should not be exceeded if the fish resources are not to be depleted. Extended deep sea fishing is much more expensive than fishing in nearby waters.

Under the assumption that butter and lard production will increase by around 1.8 percent a year and marine oils by 2.5 percent a year through 1980, the weighted average increase for the three commodities is 1.9 percent. There will, of course, be wide regional differences with regard to production and availability of these oils and fats.

But, in general, the world availability of animal fats and marine oils, which compete with vegetable oils, are not expected to increase through 1980 at a rate in excess of the 1955-68 trend. Thus, the above competing products are not expected to bring greater pressure on vegetable oil prices than they have in the past--and may bring even less.

Urea is a synthetic nitrogenous compound that is convertible into protein by bacterial action in ruminant animals. To be of value, it must be fed with fermentable carbohydrates such as the starches in grain or the sugar in molasses. It may contribute only up to one-third of the protein equivalent in finishing rations or one-fourth in growing rations. One ton of food-grade urea combined with 6 tons of cereal grain provides the same amount of protein and nearly as much energy as 7 tons of soybean or cottonseed meal (10, chap. 2, p. 129). The use of urea has been especially prominent in the United States, where it is fed primarily to cattle. Its limited use in Europe and Japan to date is due in part to the lack of a significant feedlot fattening industry in these countries. In some European countries, urea use is regulated by law; for example Germany prohibits the sale of feed urea to farmers. However, in the years ahead the use of urea in oilcake-importing regions, especially countries which produce substantial quantities of grain, is expected to increase.

By 1980, oilcakes could well be facing substantial competition from products that are presently of minor importance. For instance, the economic feasibility of producing animal feed protein from petroleum cultures has been receiving increasing attention, especially in Europe and Japan. As of 1970, the use of such protein has been limited to experimental trials. Also, substantial production of high-lysine corn for animal feed could reduce the future market for oilcakes. Some types of high-lysine corn have a protein content of 15 percent, compared with some 9 percent for ordinary corn. High-lysine corn is expected to find its greatest use in feed for swine and to a lesser degree, in poultry rations. A major factor determining the economic feasibility of substituting high-lysine corn for oilcakes will be the high-lysine corn yield attained in relation to regular corn.

At present, data are not available that would permit quantification of the effects of the above two products. But it appears to be a safe assumption that they will have some retarding effect on the growth of oilcake demand through 1980.

Another oilcake substitute product that has been receiving increasing attention in recent years is Antarctic krill, which is used for making fishmeal. The shrimp-like krill, which are only 1 or 2 inches long at maturity, are consumed in mass by whales. The reduction in whale numbers in recent years raises the question of whether the krill themselves can be profitably harvested, processed into fishmeal by factory ships, and then transported to the principal markets. It appears that to be economically feasible, fishmeal prices would have to rise above the prices prevailing in the late 1960's (49).

12.--TRADE PROJECTIONS

The major objective of this study was to determine the future trade prospects for oilseed products of the LDC's. To assess these prospects, projections of prices, production, consumption, and trade were developed under three alternative assumptions: (1) Projection set I assumes a continuation of present production and trade policies (with some modification) and allows for moderate gains in productivity in the LDC's; (2) set II assumes that 1980 agricultural productivity and economic growth in the LDC's would be higher than projected under set I; and (3) set III assumes that 1980 agricultural productivity and economic growth in the LDC's would be lower than projected under set I. 18/ Economic development and agricultural productivity in the developed and central plan countries remain the same under all three projection sets.

In chapters 6 and 10, respectively, separate demand projections for vegetable oils and oilcake were made under the assumption that the 1963-65 price level would continue. In chapter 11, production projections were based on extrapolation of trends, with some modifications; thus, under the assumption that past trends in prices would continue. This meant upward trending prices for oilcakes but declining prices for vegetable oils. If the demand and production projections for all the regions are combined, a world surplus of 2 million tons of vegetable oil is projected to 1980, while projected production and consumption of oilcake are about in balance.

The trade projections under sets I, II, and III assume that world prices for oilcakes and vegetable oils will be at levels that will bring projected world demand into balance with projected world production. Equilibrium prices and quantities were estimated through a series of iterations or successive approximations.19/ In this approach, the demand and production projections as well as the assumptions about prices presented in chapters 6, 10, and 11 are used as initial values; they are successively adjusted until new equilibrium values are obtained for prices and quantities consistent with the assumptions specified in each projection set.

In all three projection sets, the production levels of the developed and central plan regions do not change. The production levels change only in the LDC's. However, in each projection set, consumption levels vary for all regions.

Projection Set I

The basic assumptions underlying set I projections are that there will be no substantial changes in national production and trade policies or in relative prices of substitute commodities. Under these assumptions and given the supply projections in chapter 11, oilcake prices are projected to remain at about the 1963-65 level. Vegetable oil prices, however, would be expected to decline about 20 percent below the 1963-65 level to keep world demand in balance with supply. This drop, equivalent to 1.1 percent a year, is in line with past trends in vegetable oil prices. For example, from 1955-57 through 1965-67, world vegetable oil prices, weighted by the quantity of trade of each oil in 1963-65, declined by some 15.7 percent, or 1.3 percent a year. During the same period, however, oilcake prices increased by 1.6 percent a year in response to growing demand.

18/ These assumptions are identical to those used in companion commodity studies. For more details concerning alternatives, see Rojko and Mackie (50, pp 16-19).

19/ If a complete mathematical model consisting of the appropriate supply and demand equations could have been specified, a computer could have been used to estimate a set of equilibrium values simultaneously for each alternative--sets I, II, and III. However, construction of such a model was not feasible in this study.

Production levels of oilseed products as shown in chapter 11 (which assumed continuation of past trends in prices) were also used in set I. It is assumed that increases in productivity will temper the rise in oilcake prices. It was not within the scope of this study to develop supply responses to price. If information on supply response had been available and incorporated into the estimation process, the overall projected level of prices might be somewhat higher, particularly oilcake prices.

Vegetable Oils

Relative to the demand projections developed in chapter 6, the 20-percent price drop in vegetable oils increased quantity demanded in the developed, central plan, and less developed regions by 3, 7, and 10 percent, respectively. The percentage increase is greatest for the LDC's because of their higher price response.

The above projections include the implicit assumption that concessional sales of vegetable oils will continue in line with those that prevailed during the historical period. As indicated on pages 10-11, U.S. PL 480 shipments of vegetable oil appear to have had a buoying effect on world vegetable oil prices. If concessional sales of vegetable oil, on a world basis, are greater by 1980 than they were during the 1960's, one could conclude that world prices would decline at a lesser rate than the projected rate of 20 percent under set I. This would require that the increase in concessional sales would not displace commercial trade.

Highlights of projected changes in regional net trade levels from 1963-65 through 1980 under projection set I are:

(1) In the less developed regions--

(a) South America would switch from an importing to an exporting region.

(b) The export availability from the East and West Africa region and the East Asia and Pacific Islands region would increase by around 1.0 and 2.1 percent a year, respectively.

(c) Import requirements of Japan, Central America and Mexico, North Africa and West Asia, and South Asia would increase substantially. 20/

(2) In the central plan regions--

(a) East Europe would continue to be a moderate net importer.

(b) The USSR, a major exporter of vegetable oils in the 1960's, would neither be an exporter nor an importer by 1980.

(c) Communist Asia would become an importing region, compared to being an exporting region during 1963-65.

20/ For the South Asia region, the increase is especially sharp, from an average of 21,000 tons in 1963-65 to 1,247,000 tons by 1980. At first glance, such an increase seems most unrealistic. But it is noted that oil exports into this region in 1968 by the United States alone were in excess of 200,000 tons. Reports available up to early 1970 indicate that future oil imports by this region will continue to rise sharply. The projected import requirements for the South Asia region are considered to be reasonable providing that (a) there is a continued availability of oil on a concessional sales basis and (b) the countries in this region do not impose new policies to restrict oil imports.

(3) In the developed regions--

(a) Canada would be a net exporter of vegetable oils in 1980 rather than a net importer as it was during 1963-65.

(b) For South Africa, the opposite situation is projected.

(c) Although the importing developed regions would continue to provide the major home for vegetable oil traded, the increase in imports from 1963-65 through 1980 is only 1.9 percent a year.

(d) Export availabilities from the United States would increase substantially--from 1.2 million tons in 1963-65 to 3.6 million tons by 1980, or by 7.2 percent a year.

Oilcakes

Under set I, demand and prices for oilcakes are projected to 1980 to be at the same levels as in chapter 9. As indicated in the beginning of the present chapter, projected world demand for oilcakes at the 1963-65 price level was in balance with projected production levels in chapter 11. Thus, neither strong upward pressures nor strong downward pressures on world oilcake prices would be anticipated through 1980.

In world trade of oilcakes, the developed regions will account for 97 percent of imports in 1980 (table 36). The remaining 3 percent is accounted for by the Eastern Europe region. 21/

The EC alone would purchase some 41 percent of the 1980 world trade in oilcakes. Rising EC imports are partly due to the substitution of oilcakes for relatively high-priced grain in feed rations. Japan would import 21 percent of the world market, Other Western Europe 20 percent, and the United Kingdom 13 percent.

The developed countries are also projected to dominate the world market on the export side, with the United States providing some 71 percent of the world export supply, or 16.6 million tons. The projected increase in LDC oilcake production is substantially above their estimated increase in demand, and the resulting increased export availability is expected to find a market, primarily in the West European countries. The LDC's together are projected to provide 27 percent of the world's oilcake exports, or 6.3 million tons.

Projection Set II.--World Trade With a Higher Level of Agricultural Production and Economic Growth in the Less Developed Countries

Alternative II assumes a higher level of agricultural production and economic development in the LDC's. The projected growth rates of oilseed production in the LDC's are assumed to be 40 percent above those projected under alternative I. This level is similar to that used for other commodities of the overall study (see preface).

In the LDC's, agriculture accounts for a very large proportion of total economic activity; thus, the rates of growth in agricultural output affect rates of growth in the overall economy. Demand for vegetable oils and oilcakes under alternative II would reflect these effects.

21/ These are regional net trade estimates. Some of the net exporting regions, of course, contain importing countries.

A special study was made of the relationship between growth in the agricultural sector and growth in the total economy in each of 17 less developed countries. 22/ On the basis of the results, a set of income growth rates appropriate for alternative II was developed (app. table D-2).

Oilseed production in the LDC's in 1980 was estimated by multiplying the annual rates of growth presented in chapter 10 by 1.4. The oil and meal equivalents of the estimates were then computed to obtain the indicated vegetable oil and oilcake production.

The assumed increase in oilseed production in the LDC's is expected to result in lower world prices of oilcakes and vegetable oils than projected under set I.

Vegetable Oil

If income levels in the LDC's were to remain the same as in projection set I, a 56-percent decrease in vegetable oil prices from the 1963-65 base would be required to bring increased production into balance with demand. However, because incomes in the LDC's are assumed under set II to increase at a faster rate than under set I, the higher incomes would increase the demand for vegetable oils. Under projection set II, with the income effect included, vegetable oil prices would need to drop 31 percent below the 1963-65 level (compared with 20 percent under set I) to bring world supply and demand into balance. Consumption would be expected to increase only slightly in the developed area because of the very low price response. But consumption would increase substantially in the LDC's because of the greater response to price changes and the added income effect. The effect on trade under projection set II would be that imports would increase in all importing regions. From the export side, exports would decline slightly for the developed exporters and increase for the LDC exporters.

Oilcakes

The increase in LDC oilseed production under projection set II is equivalent to an addition of 4.2 million tons of oilcakes to world supplies. To bring this new supply into balance by increasing consumption at the world level, prices for oilcake would have to drop 13 percent from the 1963-65 level. 23/ Practically all of this increase would come from the developed area, which accounts for the bulk of the market.

22/ See ch. 7 of Rojko and Mackie (50) for a detailed explanation of this study. App. table D-2 in the present report contains the projected rates of increase in income on a total and per capita basis.

23/ The estimating equations for the United States and Canada had the wrong sign for the oilcake price coefficient but oilcake price in these instances was found to be influenced directly by the price movements of grains. Therefore, the prices of both oilcakes and grains were dropped 10 percent in these two regions. The estimating equations for the Australia-New Zealand and South Africa region and for the East Europe region did not include price variables. For these regions, implicit price elasticities based on the historical oilcake prices and demand levels were computed. The resulting elasticities were greater than 1.0 for both regions. An elasticity of 1.0 was deemed more reasonable and was adopted for determining the effect of a price drop in both of these two regions. Since the USSR and Communist Asia regions are centrally planned, and neither is a net importer, it was assumed that there would be no significant increase in oilcake consumption with a price drop in world oilcake prices.

Projection Set III.--World Trade With a Lower Level of Agricultural Production and Economic Growth in the Less Developed Countries

Projection set III assumes a lower level of agricultural production and economic development in the LDC's. The agricultural sectors of the LDC's would grow at annual rates about 30 percent lower than under set I. 24/

Vegetable Oil

World vegetable oil production under projection set III is relatively close to world consumption levels developed under set I. However, with lower incomes in the LDC's, due to their lower agricultural growth rates, the LDC demand for vegetable oils would be lower. With the price effect from the reduced production of vegetable oils being offset somewhat by reduced incomes in the LDC's, world vegetable oil prices would have to be higher than they were under projection set I; but they would still be 13 percent below the 1963-65 level to bring import requirements into balance with exportable supplies. The regional trade levels under set III do not vary greatly from those of set I (tables 36 and 40 provide the comparison).

Oilcake

With declining oilseed production in the LDC's, the 1980 world supplies of oilcakes would be 3 million tons lower than under set I. It was projected that an 8-percent increase in world prices would be required to bring supply and demand into equilibrium again. The adjustment in consumption resulting from the price increase would be mainly in the developed regions (tables 37 and 41 illustrate the difference).

Production Changes by Commodity

As shown in tables 42 and 43, production trends for individual commodities differ under each of the alternatives discussed above. The differences are greatest among the major oilseeds produced in the less developed countries: palm oil, peanut oil, cottonseed oil, and coconut oil. The bulk of the differences in oilcake production are found in peanut meal and cottonseed meal.

The percentage of increase, or decrease, in each commodity relative to projected world production of each commodity is also presented in tables 42 and 43. Under set II--the assumption of a 40-percent growth rate in production in the LDC's--world supplies of palm oil would be 36 percent higher than those of alternative I; peanut oil, 19 percent higher; and cottonseed oil, coconut oil, and palm kernel oil, all 14 percent higher. Olive oil and soybean oil would be higher by around 2 percent. Among oilcakes, the higher rates of production growth in the LDC's result in projected world supplies of peanut meal 19 percent above those of alternative I; copra meal, 15 percent; and cottonseed meal and palm kernel meal, some 12 percent. Soybean meal supplies would be only 2 percent higher, and rapeseed and linseed meal supplies, 4 percent higher.

Because the production levels of both meals and oils vary substantially by commodity, the price pressures would also vary among commodities. As discussed in chapter 2, the various vegetable oils and oilcakes are substantially substitutable, one for another, yet there remain some important distinguishing characteristics. Thus, the estimated

24/ Estimated income growth rates associated with lower growth rates in the total agricultural sector of these regions are shown as alternative III in app. table D-2.

price changes required to bring about world trade equilibrium would not be absorbed equally by all vegetable oils and oilcakes. The lauric oils--coconut oil and palm kernel oil--have demand schedules quite different from those of the other vegetable oils. This study did not try to estimate the effect that diverging production trends would have on the prices for individual oilseed commodities; this would require a separate study. The projected changes in world prices developed for oilcakes and vegetable oil under the different production alternatives should be considered "weighted average price" changes, and individual commodity price changes should be expected to vary from the estimates.

The price changes among the oilseeds, as such, would also be expected to differ because of variations in prices of the oils and meals derived from them, and because some oilseeds have a high yield of oil and a low yield of meal, while others have the reverse. Since future price ranges are projected to be greater for oils than for meals, the price of a high oil-yielding oilseed would range more widely than would the price of a low oil-yielding oilseed. Soybean prices are the least dependent on the fats and oils market, while the prices of oil palm kernels are the most dependent (table 44).

Structure of the Oilseed Crushing Industry 25/

The preceding regional projections, made on a meal and oil equivalent basis, do not specify whether future trade by the less developed countries will be primarily in the form of oil and meal, or in the form of oilseeds as such. The value added in crushing is estimated to be generally less than 10 percent. Thus, the increase in export earnings from the export of oil and cake rather than seed would average less than U.S. $15 per ton of seed. Nonetheless, this represents a valuable increment in LDC's, where alternative investment opportunities may be limited.

This report does not attempt to estimate the growth of the oilseed crushing industry in the LDC's through 1980. However, the possible effect such growth may have on an LDC's trade earnings, or cost, warrants a review of the structure of the world oilseed crushing industry.

Practically all of the major producers of oilseeds among the LDC's are anxious to expand their oilseed processing industries. The industrialized countries, both importers and exporters, are also willing to expand their "crush" capacity. Since a further expansion of the crushing industry will be required by 1980, the question is whether this increase will take place in the developed or the less developed regions. Location of economic activitiy is commonly determined by some geographic advantage in production efficiency, or by economics of transportation.

Modern oil milling is a rather capital intensive operation, whether conducted in a developed or less developed country since it is generally profitable to use mechanical handling equipment even where unskilled labor is plentiful. Thus, there is relatively little difference between the plant and machinery required in a developed and a less developed country.

There is no technical reason why the same equipment should be more or less efficient in one location than in another. Also, the processing costs, based on different studies, do not appear to vary sharply from one region to another. Freight rates differ from country to country, by the type of oils and seeds involved and according to the arrangements crushers have with shippers. In general, the shipping of oil and cake rather than seed appears neither to offer any substantial freight advantage nor to add significantly to freight costs.

25/ This section is drawn from (23).

Since neither processing nor transporation efficiency appear to offer dominant economic reasons for future expansion of the oilseed industry in one region or another, future expansion of the industry in the LDC's will probably be determined by small differences in these and a number of other factors. Other determining factors include:

(1) Access to markets. It may be difficult for seed crushers in the LDC's to find markets for greatly expanded output.

(2) Tariffs. Since the value added by processing is generally less than 10 percent of the value of the raw materials, relatively small differences between the tariffs on oilseeds and on equivalent quantities of vegetable oils and oilcakes can be a major deterrent to the expansion of seed crushing in the LDC's.

(3) Productivity of capital. The returns on capital invested in seed crushing are generally small. Thus, more profitable alternative uses of capital are likely to be numerous, especially in the capital-scarce LDC's.

(4) Speculation. Perhaps as important as efficiency in processing is the timing and direction of sales. Processors in the exporting countries, being further from the final market, are at some disadvantage. However, processing does permit the exporting countries to send their oil to one market and their meal to another. The projections in this report indicate that the future vegetable oil market lies primarily within the LDC's, while meal exports will continue to flow primarily to the developed countries.

(5) Industrialization. Other considerations may prompt governments of LDC's to encourage seed crushing. Advantages include the training of industrial labor and the stimulus to the development of auxilliary trades which may affect taxation and other policies.

1/ Set I assumes a continuation of present production and trade policies (with some modification) and allows for moderate gain in productivity in the LDC's.

2/ All regions except U.S. are availabilities.

3/ Does not include stocks.

4/ Includes an allowance for U.S. stocks.

13.--IMPLICATIONS FOR THE LESS DEVELOPED COUNTRIES

Given the trade projections developed in chapter 12 for oilcakes and vegetable oil, this chapter discusses the potential export earnings of and import costs to the less developed countries.

Vegetable Oil Export Earnings and Import Costs

For the LDC's as a group, total net export earnings for vegetable oils by 1980 are projected to decline considerably compared with the 1963-65 net trade earnings. This occurs not because of a sharp drop in earnings from the net exporting regions, but because of a large increase in the cost to the net importing regions.

Total vegetable oil earnings of the exporting regions during 1963-65 averaged $669 million while total costs to the importing regions totaled $92 million (table 45).

Under projection set I, total export earnings are projected to reach $694 million and import costs are forecast to rise to $607 million. Export earnings by the East Asia and Pacific Islands region are estimated to increase slightly over the average for 1963-65. For the East and West Africa region, earnings are projected to decline somewhat. The South America region, a net importer during 1963-65, is placed as a moderate exporter by 1980. Projected import costs are substantially greater for all regions than during 1963-65. The major change is for the South Asia region: for import costs to approach the projected level of $332 million, vegetable oil would probably have to continue to be available under concessional terms, and restrictions on imports avoided.

Under projection set II (higher production and income levels in the LDC's), earnings of the exporting regions are only a little higher than under set I, because the projected increase in domestic demand due to higher incomes nearly offsets the projected increase in production. The projected increase in demand in LDC importing regions, however, is substantially greater than the projected production increase. As a result, import costs rise sharply and total import costs of the LDC's for vegetable oil exceed earnings.

The situation is reversed under set III. As a result of the assumed decline in incomes, demand drops faster than production. Compared with the export earning levels under set I, the earnings for the exporting regions are lower by only $92 million, while the import costs drop by $173 million.

Oilcake Export Earnings and Import Costs

The LDC's export earnings from oilcakes by 1980 are projected to be substantially greater than during 1963-65, when they averaged $236 million. Under projection set I, such earnings are placed at $364 million, and under set II, at $592 million. Under set III, even though the Other Asia region becomes a net importer of oilcakes, the net earnings for all LDC's are $262 million, which is still above the 1963-65 level (table 46).

Total Export Earnings and Import Costs

Total LDC export earnings from oilseeds and oilseed products are projected to be higher under all three alternatives than they were during 1963-65. Total earnings averaged $905 million in 1963-65, and are projected to reach $1,058 million under projection set I; $1,269 million under set II; and $952 million under set III (table 47).

Import costs to the LDC's for oilseed products are projected to rise most sharply through 1980. Averaging $92 million during 1963-65, they are projected to reach $607 million, $697 million, and $522 million under sets I, II, and III, respectively. The bulk of this increase is accounted for by the projected rising import demand for vegetable oil by the South Asia region.

As a result of the projected increase in import costs, the net earnings from oilseed products for the LDC's as a whole are projected to be lower under all three sets than during 1963-65.

Per capita consumption of oilseed products is projected to rise through 1980, even though LDC net export earnings from oilseed products are not; and regardless of the fact that the populations in LDC's are expected to continue to increase at very high rates. LDC's may find it difficult to achieve a consensus on trade policy, since the less developed area includes both importers and exporters. Lower world prices benefiting importers would adversely affect exporters, and higher world prices benefiting exporters would adversely affect importers.

Methodology Used To Determine Values

While the trade projections were developed on an oil and meal equivalent basis of the seeds, trade occurs in the form of meal, oil, and oilseeds. Primarily because of crushing and margin costs, the value of meal and oil traded in the form of unprocessed oilseeds varies from the value of processed meal and oil. In view of these value differences, one cannot simply take a price for meal and a price for oil and apply that to the projected volume of trade to arrive at a region's export earnings or costs. To determine the value of the combined meal and oil trade and to allow for some trade in unprocessed form, the following procedure was used. The example is for a region projected to be a net oilseed exporter; similar steps were followed for net importers.

(1) The average value of each of the region's 1963-65 oilseed exports was obtained (app. A tables). The composition of the region's oilseed exports was computed by determining the value of each oilseed as a percentage of the total gross oilseed export value.

(2) This percentage value for each oilseed was then multiplied by the total value of the region's net oilseed export earnings to allocate the value of each oilseed with respect to net export earnings. (The net export earning values which were used are given in app. A tables).

(3) The value of oil and meal in each oilseed was computed by multiplying the net value of each oilseed by the percentage share of total value of oil and meal derived from each oilseed (table 44).

(4) These computed values of oil and meal (exported as oilseeds) were then added to the region's net actual values of oil and meal exported as such (1963-65 average). The resulting totals give a 1963-65 average value for the region's net exports of oilseeds, oil, and meal on an oil and meal basis only.

(5) The region's 1980 net export earning values from vegetable oil were estimated by multiplying the 1963-65 net values by the change in net quantity exported between 1963-65 and 1980 projected. This was done for each alternative. The values obtained were adjusted by the difference in estimated price levels that would bring world demand and supply into equilibrium. A similar procedure was used to determine meal values.

This procedure assumes that the composition of a region's trade in oilseeds, oils, and meals would not change significantly between 1963-65 and 1980. Should a region change from an exporter of oilseeds to an exporter of oils and meals, the increased value received would be approximately 10 percent of the value of the oilseeds.

APPENDIX C.--DESCRIPTION AND USES OF OILSEEDS AND OILSEED PRODUCTS

Oilseeds 1/

Soybeans

Hundreds of varieties of soybeans are known. In general, the cultivated soybeans are erect plants, growing in some cases to a height of over 3 feet. The hairy pods are borne in clusters of 3 to 5 and range from 1.5 to 3.5 inches long. The plant, a summer legume, has about the same climate and soil requirements as corn, but the time required to mature can vary from about 75 to 200 days, depending on the variety.

Peanuts

The peanut plant, an annual legume, yields kernels enclosed in a fibrous pod that develops from a peduncle thrust into the ground. The peanut kernel generally accounts for around 70 percent of the combined weight of the kernel and the pod (or shell). The peanut is a many-branched plant somewhat resembling clover in its foliage, but with quadri-foliate leaves. After the small single blossoms have bloomed, the flower stems bend down and force the little pods into the soil, where they develop and mature. Peanuts are variously known as arachis nuts, earth nuts, groundnuts, and by other names in different localities. The plants thrive best in light sandy soils well provided with plant foods in regions where the rainfall during the growing season does not exceed 26 inches.

Cottonseed

Cottonseed is a byproduct of the cotton plant. The oil and protein content of cottonseed vary depending on the variety of cotton and soils, locality, and seasonal and climatic conditions. The hulls vary from about 40 to 55 percent of the seed, and the kernels or meats vary from 44 to 61 percent. The hulls contain 0.3 to 1 percent oil and the kernel 28 to 40 percent. As a rule, seed from a long-staple cotton has the higher oil content.

Sunflowerseed

Sunflowers grow best in a warm summer climate and rich deep soils Sunflower varieties can be divided into the tall or giant types that reach a height of about 8 to 14 feet; dwarf types that reach 4 to 7 feet; and intermediate types. The tall varieties are the main ones grown in the United States, where the seed is grown principally for birdseed. As an oilseed crop, the dwarf varieties are preferable since their shorter and more uniform height makes mechanical harvesting more practical.

In recent years, Russia has developed new dwarf varieties that are vastly improved with respect to length of the vegetative cycle, homogeneity of the crop, and resistance to disease. The oil content has also been increased considerably. Approximately 80 percent of the world's sunflowerseed oil is now from the improved varieties.

1/ This section draws heavily from (11).

Rapeseed

Rape is very closely related to field mustard and to the rutabaga. It resembles the latter in many ways except that the tap root of rape does not thicken into a tuber. Plants grow 2 or 3 feet high and have thick, succulent leaves and stems. Varieties that are planted early and produce seeds in the same year are known as summer rape, while those that live in the winter and mature their seeds in the second year are known as winter rape. Rape production is confined almost wholly to the temperate and warm temperate zones.

Coconut

Coconut palm cultivation is restricted to a relatively narrow belt within the tropics. The trees grow best in areas with high temperatures, high rainfall, and alluvial soils. These conditions are found mainly on coastal regions or islands.

The tree usually grows 50 to about 100 feet high. The trunk terminates in a crown of about 20 pinnately compounded leaves 12 to 15 feet long. The flowers are borne in spadices that appear in the axils of the leaves. The trees begin to bear nuts in the sixth or seventh year and they bear in quantity when 10 or 12 years old. The nuts take 9 to 12 months to ripen and may be harvested several times a year. Mature trees on well-managed plantations may yield about 60 nuts. Plantations contain some 60 to 80 trees an acre. Most coconuts are produced in small groves, however, where the number of nuts per tree is well below 60. One coconut yields approximately 2 pounds of copra.

Copra is the dried kernel or "meat" of the coconut from which the coconut oil is expresssed. Fresh coconut contains 30 to 40 percent oil, while copra usually contains 60 to 65 percent.

Oil Palm

The oil palm is a perennial that yields several "palm bunches" in the crown of the tree. Each bunch may contain 200 to 2,000 individual fruits. Each individual "palm fruit" is approximately 2.0 inches in length and about 0.75 inch in diameter. The fruit contains three main parts: (1) the outer fleshy pulp, or pericarp, which contains the palm oil; (2) a hard-shelled nut called the palm nut, which is enclosed by the pericarp; (3) inside the nut is the palm kernel which yields palm kernel oil and cake. The fibrous residue remaining after the palm oil has been expressed from the pericarp is of little value and is sometimes used as fuel, as are the shells from the palm nuts. Palm oil is high in palmitic acid, while palm kernel oil is high in lauric acid.

After they are ripe, palm fruits cannot be allowed to hang long on the tree, but must be harvested within 6 to 9 days to prevent the formation of free fatty acids which make the palm oil inedible. The fruits ripen in about 6 months; two crops a year are obtained. While some fruit is harvested every month, two peaks of production usually occur.

The kernel and the shell are a large part of the whole fruit. To increase the oil palm yield, new varieties of oil palms with a smaller shell are being developed. The palm oil and palm kernel oil yields of the various varieties of oil palm vary considerably.

The best soils for oil palms are well-drained loams or light clays located in flat coastal lands or inland alluvial plains up to 1,000 feet in altitude. Rainfall of 100 inches or more, well distributed throughout the year, and a climate free from prolonged cold spells are desirable.

Olives

Despite the ability of olive trees to grow in the poorest types of soil, they flourish only in areas with a Mediterranean-type climate. This climate can be summarized as a long intensely hot summer; a relatively mild and rainy winter; and a short intermediate fall and spring. Olive trees require a minimum amount of rainfall in comparison with other crops in the Mediterranean region. A prolonged hot summer is necessary for the fruiting and the maturity of the olive crop.

It takes 6 or more years for an olive tree to mature into production. The profitable fruit-bearing period can be put at a minimum of 50 years in dry zones and much longer in areas of more favorable conditions. Many varieties of olive trees have been developed over the centuries. Olive production often follows a 2-year cycle, with a good crop being followed by a medium or poor crop.

Olives gathered for oil production are highly perishable and must be processed shortly after harvest to ensure good quality and yield. Most other oilseeds, of course, can be stored. The major component of olive oil production is labor. The general availability of cheap labor is a major reason why the olive oil industry has continued to flourish in the less developed parts of the Mediterranean region.

During 1960-65, some 96 percent of the total olives produced were utilized in oil processing; the remainder were eaten directly (2, p. 10). Olive kernels contain oil similar to that found in the pulp; therefore, in processing, the kernels are generally not separated from the rest of the fruit.

Flax

Flax grown to produce fiber for making linen and flax grown for its oilseed belong to the same species, but are of different varieties, and generally speaking, the two products are not obtained from the same crop. The varieties of flax grown for fiber have long stems with relatively few branches, while the varieties grown for oilseed have shorter stems and more branches and produce a greater quantity of seed.

Flax is an annual crop which is grown in many parts of the world, principally in temperate regions. It is grown primarily as a rainfed, cold-season crop and thrives best in heavy soils with high moisture-retaining capacity.

Vegetable Oils 2/

A frequent subclassification of fats and oils (not only vegetable oils) is "hard" and "soft" oils. In temperate climates, the soft oils are liquid and the hard oils are not. In general, a hard oil has relatively more saturated than unsaturated fatty acids, while just the opposite is true of a soft oil. Crudely speaking, fatty acids are called unsaturated if they can absorb more hydrogen atoms; they are called saturated if they are resistant to more hydrogen atoms.

2/ This section draws heavily from (41).

A breakdown of the vegetable oils in this study into the "hard" and "soft" classification follows:

Hard Oils	Soft Oils
Coconut	Olive
Palm kernel	Rapeseed
Palm	Peanut
	Cottonseed
	Sunflowerseed
	Soybean

Generally speaking, there is a direct relationship between the fatty acid composition of the oil and important qualities such as melting point, texture, and plasticity. The hard oils, because of their relatively large amount of saturated fatty acids, have a higher melting point than do the soft oils. Plasticity, the ability to retain a shape attained by pressure deformation, is enhanced when there is a broad and balanced representation of the several fatty acids.

Processing of Vegetable Oil

The following material discusses (1) the manner in which oil is taken from seeds (or kernels); (2) the oils that require further processing; and (3) the processing steps. (The hydrogenation process occurs after the initial processing and is discussed later).

Crude vegetable oils are obtained from seeds by pressing (expelling) or by chemical extraction. The chemically-extracted oils have to be processed further before they may be used; however, the pressed oils may or may not be used without further processing.

Five of the processing steps in the refinement of crude oil are: (1) saponification, (2) bleaching, (3) deodorizing, (4) degumming, and (5) winterizing. Not all of the vegetable oils have to go through these five steps. The chemically extracted oils must go through the saponification process, but the expelled oil may or may not be saponified.

Saponification involves the use of alkali neutralizers such as sodium hydroxide to isolate and remove certain impurities in the crude oil. During the process, the undesirable fatty acids (free fatty acids) are eliminated; but unfortunately, some oils also lose varying amounts of pure oil at the same time. For example, palm kernel oil has a higher loss than does coconut oil, and this increases the price differential of palm kernel oil relative to that of coconut oil.

Bleaching involves mixing the oil with a substance that has a high color-absorbtion power (such as diatomaceous earth, carbon black earth, or active earth) and then straining the mixture, leaving the color behind with the absorbing agent.

In addition to getting rid of undesirable color, odors and gum-like substances may be eliminated and oil may be winterized. Winterizing is necessary for cottonseed oil and the degumming is necessary for soybean oil.

In the winterizing step, the temperature is decreased to 35° F. and those parts of the oil that would solidify are precipitated out. This step for cottonseed oil and the degumming step for soybean oil increase the price differential of the oils relative to other vegetable oils. However, with the exception of these price differentials, vegetable oils generally have the same processing costs.

Hydrogenation of Vegetable Oils

The fact that hard oils have a relatively higher level of saturated fatty acids than do soft oils does not mean that these levels have to remain unchanged. Since hydrogen is a colorless, tasteless, odorless, and very light gas and hydrogenation is the process of exposing to or treating with hydrogen, the level of saturated fatty acids may be adjusted upward by the process of hydrogenation. If a selective process is used, all acids are affected at about the same time. Selective hydrogenation is generally used, as it gives the end product a higher resistance to oxidation and, therefore, less likelihood of becoming rancid.

Uses of Vegetable Oils

Vegetable oil uses may be broadly classified as edible and inedible. Edible uses include vegetable oils being used in (1) margarine, (2) salad oil, (3) cooking oil, (4) shortening, (5) confections, and (6) filling for baked goods. Inedible uses of vegetable oils include use in (1) soaps (as a lathering agent), (2) paints (as a drying agent), (3) lubricants, (4) cosmetics, (5) pharmaceutical preparations, (6) textile lubricants, (7) printing inks, (8) linoleums, and (9) varnishes.

Soybean oil.--Considerable quantities of soybean oil are used in salad oils and cooking fats. Blends of soybean oil with olive oil are used extensively. However, the use of the soybean oil for these purposes is limited to some extent by its tendency to develop a bad flavor or odor when stored in contact with air, or when heated to the temperatures used in deep fat frying. This problem is called "reversion."

Reversion is due mainly to the fact that the soybean oil contains linolenic acid. Hydrogenation, which saturates the linolenic fatty acids, greatly reduces the oxidization problem. Thus, the major use of soybean oil is in the manufacture of margarine fats and household shortenings. Even in these products, however, the percentage of soybean oil has to be limited since the oil continues to revert faster than do the other oils.

Peanut oil.--Peanut oil is well suited for use either unhydrogenated or hydrogenated. The unhydrogenated oil is valued as a salad and cooking oil because it remains liquid at refrigerator temperatures, is highly stable and nonfoaming at high temperatures, and is easily deodorized to be tasteless. As a salad oil, however, it has a greater tendency to cloud when held at low temperatures than do most other oils used as salad oils. Peanut oil is widely used in the manufacture of vegetable margarines; it is also used to some extent for cooking sardines prior to canning in olive oil. Inedible grades of the oil are used chiefly in soap.

Cottonseed oil.--Cottonseed oil makes an excellent salad oil provided a portion of the solid glycerides is removed by the winterizing process. The oil is easily deodorized to a bland flavor and keeps relatively well. It is well suited to shortening and margarine manufacture.

Sunflowerseed oil.--Sunflowerseed oil is well suited for use as a salad and cooking oil, and when hydrogenated, for use in margarine fats and shortening. Good grades of the oil may be refined with a low loss. The linolenic acid found in soybean oil is lacking in sunflowerseed oil, which is to the advantage of sunflowerseed oil when used as a food. The oil is also a good material for the manufacture of oil-modified alkyo resins and similar products.

Rapeseed oil.--Until recently, rapeseed oil was at a competitive disadvantage on world markets as an edible oil because of its high erucic acid content, which gives an unpleasant taste and odor, especially when heated. Recent technological improvements in rapeseed processing techniques have largely overcome this problem. Its uses for all edible oil purposes is expected to increase in the future.

Coconut oil.--Coconut oil, as palm kernel oil, differs sharply in physical characteristics and chemical composition from most other oils. The most noticeable physical characteristic is that the oil changes abruptly from a hard and brittle solid to a clear oil within a temperature range of a few degrees. About 90 percent of the fatty acids in the oil are saturated and nearly half of these consist of lauric acid.

Coconut oil is well suited to margarine formulations where a butter-like consistency is desired. Because the oil has a low degree of unsaturation, it is resistant to rancidity caused by oxidation and therefore can be used in confections and other products which may stand for some time before consumption. The oil is not well suited for shortening and cooking fat manufacture because of its narrow plastic range.

Coconut oil is used extensively in soap manufacture (its lauric oil content yields excellent lathering characteristics) and in the chemical industries, primarily for synthetic detergents. Most industrial uses of coconut oil have become vulnerable to replacement by synthetic raw materials.

Palm oil.-- Palm oil is widely used in margarine, shortening, and cooking fat because of its soft texture, long plastic range, high melting point, and stability. The refined oil is resistant to oxidation because of its moderate degree of unsaturation. It has a good flavor and keeps well. The large portion of palmitic acid in palm oil also makes it well suited for soap making.

Palm kernel oil.--Palm kernel oil has essentially the same characteristics and properties as coconut oil does, as well as most of the same drawbacks and advantages. Consequently, palm kernel oil is used more or less interchangeably with coconut oil. Refining losses, however, are higher with palm kernel oil. Palm kernel oil refining costs have been approximately 1 cent higher a pound than such costs for coconut oil, resulting in a market differential of that amount between the two oils.

Olive oil.--Olive oil is seldom hydrogenated to plastic shortening consistency since cookery methods in the Mediterranean countries, where olive oil is primarily consumed, were developed on the basis of using the oil in liquid form. Good grades of virgin olive oil have a pleasing delicate flavor, which is probably the reason for its high price relative to that of other oils. Olive oil is also used for a variety of other purposes, including the manufacture of soaps, textile lubricants, cosmetics, and pharmaceutical preparations.

Oilcakes 3/

In general, oilcakes are used as a protein concentrate in animal feeds. The main components of oilcakes are protein, oil, fiber, nitrogen-free extract, and mineral matter. The average composition of the various meals is presented in table C-1. The components other than protein are more important in compound feeds for poultry and hogs than in such feeds for cattle.

3/ This section is drawn from (45, ch. XXII) and (10, vol. II, ch. II).

Protein is the general term used for some 24 or more amino acids. 4/ Amino acids that cannot be made in the body from other substances or that cannot be made in sufficient amounts are called essential amino acids. Protein for the growth of protein tissues or for the formulation of milk cannot be made by an animal unless it has an adequate supply of each of the essential amino acids. A shortage of a single one in a feed ration will limit the use of all the others and therefore reduce the efficiency of the entire ration. The essential amino-acid pattern in protein by type of oilcake is presented in table C-2; that of fishmeal is included for comparison. In the processing procedure, variations in temperature, pressure, and retention time inside the cooker, for example, cause marked differences in the protein content of an oilcake. Thus, an oilcake from one particular oilseed from some suppliers obtains a premium price over other oilcakes from the same oilseed.

Comparison of the Nutritive Values of Different Cakes

Cakes of different oilseeds processed in different manners possess different amounts of protein, oil, and fiber. Digestibility of each of these components differs widely depending on the type of animal to which the oilcake is fed. Hence, it is most difficult to theoretically compare a nutritive value of the different cakes. The feed requirements of the animal must be considered along with the digestibility coefficient of each oilcake.

Uses of Individual Meals

Soybean meal.-- Soybean meal is one of the best protein supplements for dairy and beef cattle. For swine and poultry, it ranks ahead of all other common protein supplements of plant origin because of the higher quality of its protein. Soybean meal lacks methionine and vitamins, especially as a feed for chickens; another disadvantage is its limited phosphorous and calcium content.

During processing, soybean meal is subjected to toasting, which destroys the tripsin-inhibitor which is toxic when fed to animals.

Cottonseed meal.--This product is a good protein supplement for dairy cows, beef cows, and sheep. Cottonseed meal, however, does not furnish protein of high quality for swine or poultry, chiefly because it is rather low in lysine. Therefore, it should be used in combination with such supplements as tankage, meat scraps, fishmeal, milk byproducts, or soybean meal. Cottonseed meal is one of the richest feeds in phosphorous but it is low in calcium.

The toxic compound Gossypol in cottonseed meal (up to 1 percent of the ration) has no effect on ruminants, but care has to be taken in feeding the oilcake to pigs, poultry, and calves.

Linseed meal.--Linseed meal is a high-protein and palatable feed for dairy cattle, beef cattle, and sheep. It seems to have a conditioning effect on cattle and has a slight laxative effect which aids in keeping stock healthy. Since linseed meal is deficient in lysine and methionine, it should be used in combination with other protein supplements when fed to swine or poultry. Also, when fed in amounts larger than 5 percent of the total ration, it has a depressing effect on the growth of chicks and poults.

The toxicity due to linase in linseed meal is generally destroyed by the high temperature of operation during screwpressing.

4/ Generally speaking, extracted cakes are as good a protein concentrate as expeller cakes with a higher oil content. Expeller cakes, however, are preferred in some countries perhaps because of their better palatability or the extra energy the oil adds to the cakes.

Sunflowerseed meal.--Sunflowerseed meal is a good feed for stock and keeps well. The main disadvantage is the low-lysine content for feeding poultry and swine. Also, the quantity of hulls added to the kernels and the method of processing can limit the use of this meal in swine and poultry feeds because of its high-fiber content. Sunflower meal can be used as a supplement to soybean meal since it is rich in methionine, vitamin B12, and calcium and phosphorus.

Copra meal.--Copra meal is a good feed supplement for cattle, particularly dairy cattle, because of its protein content, the characteristic of its residual oil, its palatability, and its high capacity for absorbing molasses. It is not a good feed for swine and poultry because of its high-fiber content.

The meal's lysine content is high, and lysine is the limiting amino acid in feeding non-ruminants. Copra meal contributes significant amounts of the B complex vitamins to rations.

Peanut meal.--Peanut meal is a good and palatable supplementary protein concentrate for dairy and beef cattle. It is also a good supplement for mature hogs but it produces soft pork. For chicks and young pigs, it is primarily deficient in methionine, cystine, lysine, and trypotophan.

Many compound feed manufacturers have generally stopped using peanut meal in feed for poultry and young pigs because of the danger of aflatoxin--which can be fatal.

Rapeseed meal.-- The use of rapeseed meal has been limited in livestock feeding because of the presence of active goitrogens. Goitrogens are enzymes that cause the meal to be toxic to animals--particularly poultry and pigs, in which it causes growing problems and may lead to death. Recently, however, processing methods have been developed to improve the quality and nutritional value of the meal as an animal feed. Although rapeseed meal is not especially palatable, it has a protein content of around 35 percent with a good amino acid balance. Its use for animal feeding will probably expand in the future.

Palm kernel meal.--This meal varies considerably in composition and especially in fiber content. Palm kernel meal has been used chiefly in Europe, where it is mostly fed to dairy cows.

Palm kernel meal tends to produce hard fat when fed to stock and thus makes a firm butter and pork of good quality. It is not very palatable to pigs and should not form more than about one-fifth of a ration.

Table C-1.--Composition of various oilcakes

Oilcakes	Protein	Fat	Fiber	Nitrogen free extract	Mineral matter	Moisture
				-Percent		
Peanut expeller (decorticated)	46.6	6.3	5.5	30.2	5.4	6.0

APPENDIX D.--WORLD POPULATION AND INCOME, BY REGION, 1965 AND PROJECTED TO 1980

Population Projections

Population is the key variant in growth of demand. Thus, assumptions regarding population growth are critical in analysis of demand prospects for agricultural exports. Original research on population growth, however, was not within the intent of this study. A number of world demographic studies have been conducted. Population growth rates used for analytical purposes and projections were based, with some modifications, on population projections of the Population Division of the United Nations. However, some adjustments were made based on recent studies by FAO, OECD, and the USDA's long-term supply and demand studies.

For this study, a single population projection was selected for each region (table D-1). Considerably higher growth rates were used for the LDC's than for the rest of the world. It was not deemed necessary to develop high and low population projections, although major changes in growth rates will affect the projections.

Income Projections

Another key demand variant is income growth. With given levels of population, prices, and other factors, the rate of increase in income largely determines the pattern and level of per capita consumption. Population may be the most important demand factor in the LDC's, but income may be more important in countries with low population growth rates. In Japan, for example, population growth is less than 1 percent and income growth is over 8 percent.

Table D-2 presents the projected growth rates in national income that were used in this study and also shows the levels in dollar terms.

The income growth rate in the LDC's is as high or higher than that for the developed regions. However, the high rate of population growth in the LDC's reduces their per capita income levels and per capita income growth rates.

For the LDC's, separate income projections were generated for alternatives II and III. It was assumed that changes in income growth were associated with changes in oilseeds production in the LDC's. 1/ Therefore, the rates of income growth for the LDC's were adjusted with the shifting production functions--up for alternative II and down for alternative III.

1/ For more details concerning alternatives, see Rojko and Mackie (50, pp 16-19).

APPENDIX E.--A SIMULTANEOUS MODEL FOR DEVELOPING DEMAND ESTIMATES FOR OILSEEDS AND OILSEED PRODUCTS

The oilseed economy is interesting in that factors influencing demand for vegetable oil and demand for oilcakes are not the same, while supplies of the two products are tied together by the parent commodity, oilseeds. A simultaneous model was developed to help analyze the interrelationships and price behavior.

An exploratory model required 29 relations to fully explain the interdependency between one importing country and one exporting country producing one oilseed, converted into a vegetable oil product and an oilcake product.

Because of a lack of information for variables such as stocks, crushings, and crushing margins, it was not possible to determine statistically all of the relationships. Development of the exploratory model, however, yielded insights into the workings of the total system, which in turn, led to a better choice of variables in the limited relations that were used in projecting oil and meal demand.

A description of the simultaneous model follows for use of researchers who may be interested in more fully exploring this approach to analysis of demand for and supply of oilseed products.

The Simultaneous Model 1/

The simultaneous model developed was devised in terms of world trade based on the structure of the oilseed market (fig.4). Exporting regions were the suppliers and importing regions were the demanders of the oilseeds, meals, and oils. The interdependency of the two kinds of regions was worked out by a set of identities called the regional equilibrium conditions. The equations in the model are consistent with assumptions made from economic theory and empirical knowledge of oilseed markets.

The model has 29 equations containing endogenous and predetermined (exogenous plus lagged endogenous) variables. Four sets of equations for behavioral and technical relationships in world trade and a set of identities for regional conditions were established. The number of equations and variables in the model could be expanded or reduced. Descriptions and identifications of variables begin on page 206.

Behavioral Relationships

The behavioral relationships for the importing regions are given in equations (1) through (16). Equations (1) and (2) pertain to domestic demand for oils and meals. Demand for oil depends on the price of oil, price of substitutes, income, concessional shipment, quantity of feeds produced, and beginning stock of feeds. Demand for meal relates to the price of meal, number of animal units, quantity of feed produced, price of tankage, and price of other feeds. Equation (3) states that production of oilseeds depends on prices of oilseeds in the current and preceding periods, prices of substitutes, and a trend-time variable. Equation (4) relates the level of crushings to prices of oilseeds, meals, and oils and to the crushing margin. Equations (5) and (6) express the ending stock of oil and meal as depending on prices and supply of oilseeds--the level of concessional P. L. 480 trade is considered as another variable in the ending stock of oil.

1/ Anthony S. Rojko, Foreign Regional Analysis Div., Econ. Res. Serv., provided most helpful guidance in the development of this model.

The set of behavioral relationships for the exporting regions is the same as the above with the exception of an additional ending stock equation (16) because of the assumption of oilseed surplus in the exporting regions.

Technical Relationships

The technical relationships help to establish the simultaneity of the system; these are stated in equations (7) through (11) for the importing regions and in equations (19) through (23) for the exporting regions.

Equation (8) establishes the fixed relationship between quantity of oilseeds crushed and the outturn of oils and meal. Equations (9) and (10) state that the supply of and demand for oils and meals are in equilibrium. Equation (11) links the oil and meal prices to that of the parent commodity, oilseeds.

Equation (19) for the exporting regions differs from (7) for the importing regions in the kind and number of variables. The reason is that the exporting regions' production and beginning stocks are the supply of oilseed required to equal domestic consumption, export, and the ending stock of oilseeds; whereas, in the importing regions, the supply of oilseeds consists of production and import to fulfill domestic demand for this commodity.

Regional Relationships

Identities (24) through (26) simply state that the quantities of oilseed, oils, and meals exported are equal to those of imports on the world level. Identities (27) through (29) relate the prices of oilseed, oils, and meals in the importing regions to those in exporting regions, with cost of transportation considered.

Description of Endogenous Variables

1. Q_o^{di} = Quantity of oil demanded in importing regions.
2. Q_m^{di} = Quantity of meal demanded in importing regions.
3. Q_{os}^{pi} = Quantity of oilseed produced in importing regions.
4. Q_m^{esi} = Ending stock of meal in importing regions.
5. Q_o^{esi} = Ending stock of oil in importing regions.
6. Q_{os}^{ci} = Quantity of oilseeds crushed in importing regions.
7. Q_o^{de} = Quantity of oil demanded in exporting regions.
8. Q_m^{de} = Quantity of meal demanded in exporting regions.
9. Q_{os}^{pe} = Quantity of oilseed produced in exporting regions.
10. Q_{os}^{ese} = Ending stock of oilseed in the exporting regions.
11. Q_o^{ese} = Ending stock of oil in the exporting regions.
12. Q_m^{ese} = Ending stock of meal in the exporting regions.
13. Q_{os}^{ce} = Quantity of oilseed crushed in the exporting regions.
14. P_o^i = Price of oil in the importing regions.
15. P_m^i = Price of meal in the importing regions.
16. P_{os}^i = Price of oilseed in the importing regions.
17. P_o^e = Price of oil in the exporting regions.
18. P_m^e = Price of meal in the exporting regions.
19. P_{os}^e = Price of oilseed in the exporting regions.
20. Q_m^{pi} = Quantity of meal produced in importing regions.
21. Q_o^{pi} = Quantity of oil produced in importing regions.
22. Q_m^{pe} = Quantity of meal produced in exporting regions.
23. Q_o^{pe} = Quantity of oil produced in exporting regions.
24. Q_m^{ee} = Quantity of meal exported in exporting regions.
25. Q_o^{ee} = Quantity of oil exported in exporting regions.
26. Q_{os}^{ee} = Quantity of oilseed exported in exporting regions.
27. Q_m^{ii} = Quantity of meal imported in importing regions.
28. Q_o^{ii} = Quantity of oil imported in importing regions.
29. Q_{os}^{ii} = Quantity of oilseed imported in importing regions.

Description of Exogenous Variables

1. P^{i}_{sb} = Price of substitute in importing regions.
2. I^{i} = Index of personal income in importing regions.
3. PL^{i} = PL 480 shipments to importing regions.
4. Q^{ii}_{f} = Quantity of fat imported for importing regions.
5. Q^{bsi}_{f} = Beginning stock of fat in importing regions.
6. A^{i} = Number of animal units in importing regions.
7. Q^{pi}_{fd} = Quantity of feedgrain produced in importing regions.
8. $P^{i}_{os\ t-1}$ = Price lag, oilseed.
9. P^{i}_{sb} = Price of substitute for oilseeds in importing regions.
10. M^{i}_{c} = Crushing margin, importing regions.
11. P^{e}_{sb} = Price of substitute in exporting regions.
12. I^{e} = Index of personal income in exporting regions.
13. A^{e} = Number of animal units in exporting regions.
14. Q^{pe}_{fd} = Quantity of feedgrain produced in exporting regions.
15. $P^{e}_{os\ t-1}$ = Last year price of oilseed in exporting regions.
16. Q^{bsi}_{m} = Beginning stock of meal in importing regions.
17. Q^{bsi}_{o} = Beginning stock of oil in importing regions.
18. Q^{bse}_{o} = Beginning stock of oilseed in exporting regions.
19. M^{e}_{c} = Crushing margin, exporting regions.
20. T_{os} = Transfer costs for oilseeds.
21. T_{m} = Transfer costs for meal.
22. T_{o} = Transfer costs for oil.
23. T = Time (trend variables).
24. P^{i}_{t} = Price of tankage.
25. Q^{si}_{os} = Supply of commercial oilseeds.

WORLD MODEL FOR OILSEEDS, MEAL, AND OIL

Importing Regions

Behavioral Relationship

1. Demand for oil: $f(Q_o^{di}, P_o^i; P_{sb}^i, I^i, PL^i, Q_f^{ii}, Q_f^{bsi} \ldots\ldots\ldots\ldots\ldots\ldots e_1) = 0$
2. Demand for meal: $f(Q_m^{di}, P_m^i; A^i, Q_{fd}^{pi}, P_t^i, Q_{fd}^i \ldots\ldots\ldots\ldots\ldots\ldots e_2) = 0$
3. Production of oilseeds: $f(Q_{os}^{pi}; P_{os\ t-1}^i, P_{sb}^i, T \ldots\ldots\ldots\ldots\ldots\ldots e_3) = 0$
4. Crushing equation: $f(Q_{os}^{ci}, P_{os}^i, P_m^i, P_o^i; M_c^i \ldots\ldots\ldots\ldots\ldots\ldots e_4) = 0$
5. Ending stock of meal: $f(Q_m^{esi}, P_m^i; Q_{os}^{si} \ldots\ldots\ldots\ldots\ldots\ldots e_5) = 0$
6. Ending stock of oil: $f(Q_o^{esi}, P_o^i; Q_{os}^{esi}, PL_o^i \ldots\ldots\ldots\ldots\ldots\ldots e_6) = 0$

Technical Relationship

7. Production and import for oilseed: $Q_{os}^{pi} + Q_{os}^{ii} = Q_{os}^{ci}$
8. Crushing for oilseed: $Q_{os}^{ci} = bQ_m^{pi} + (1-b)\ Q_o^{pi}$
9. Market clearing for meal: $Q_m^{pi} + Q_m^{bsi} + Q_m^{ii} = Q_m^{di} + Q_m^{esi}$
10. Market clearing for oil: $Q_o^{pi} + Q_o^{bsi} + Q_o^{ii} = Q_o^{di} + Q_o^{esi}$
11. Price linkage: $P_{os}^i + M_c^i = bP_m^i + (1-b)\ P_o^i$

Exporting Regions

Behavioral Relationship

12. Demand for oil: $f(Q_o^{de}, P_o^e; P_{sb}^e, I^e, Q_f^{ii}, Q_f^{bsi} \ldots\ldots\ldots\ldots\ldots\ldots e_{14}) = 0$
13. Demand for meal: $f(Q_m^{de}, P_m^e; P_{sb}^e, A^e, Q_{fd}^{pe}, P_{fd}^e, P_t^e \ldots\ldots\ldots\ldots\ldots\ldots e_{15}) = 0$
14. Production of oilseeds: $f(Q_{os}^{pe}; P_{os\ t-1}^e; P_{sb}^e, T \ldots\ldots\ldots\ldots\ldots\ldots e_{16}) = 0$
15. Crushing equation: $f(Q_{os}^{ce}, P_{os}^e, P_o^e, P_m^e; M_c^e \ldots\ldots\ldots\ldots\ldots\ldots e_{17}) = 0$
16. Ending stock of oilseeds: $f(Q_{os}^{ese}, P_{os}^e, Q_{os}^{se} \ldots\ldots\ldots\ldots\ldots\ldots e_{18}) = 0$
17. Ending stock of oil: $f(Q_o^{ese}, P_o^e; Q_o^{se} \ldots\ldots\ldots\ldots\ldots\ldots e_{19}) = 0$
18. Ending stock of meal: $f(Q_m^{ese}, P_m^e; Q_m^{se} \ldots\ldots\ldots\ldots\ldots\ldots e_{20}) = 0$

Technical Relationship

19. Supply for oilseed: $Q_{os}^{pe} + Q_{os}^{bse} = Q_{os}^{ce} + Q_{os}^{ee} + Q_{os}^{ese}$
20. Crushing for oilseed: $Q_{os}^{ce} = aQ_m^{pe} + (1-a)\ Q_o^{pe}$
21. Market clearing for meal: $Q_m^{pe} + Q_m^{bse} = Q_m^{de} + Q_m^{ee} + Q_m^{ese}$

22. Market clearing for oil: $Q_o^{pe} + Q_o^{bse} = Q_o^{de} + Q_o^{ee} + Q_o^{ese}$

23. Price linkage: $P_{os}^{e} + M_c^e = aP_m^e + (1-a)\ P_o^e$

Regional Relationships

Equilibrium Conditions

24. $Q_{os}^{ee} = Q_{os}^{ii}$

25. $Q_m^{ee} = Q_m^{ii}$

26. $Q_o^{ee} = Q_o^{ii}$

27. $P_{os}^{i} = P_{os}^{e} + T_{os}$

28. $P_m^i = P_m^e + T_m$

29. $P_o^i = P_o^e + T_o$

Figure 4

Results of the project of which this report is a part have been published as follows by the Economic Research Service:

World Trade in Selected Agricultural Commodities, 1951-65--

Vol. I.--Beverage Crops: Coffee, Cocoa, and Tea. Foreign Agr. Econ. Rpt. 40, June 1968.

Vol. II.--Food and Feed Grains: Wheat, Rice, Maize, Barley, and Other Cereals. Foreign Agr. Econ. Rpt. 45, June 1968.

Vol. III.--Textile Fibers: Cotton, Jute, and Other Vegetable Fibers. Foreign Agr. Econ. Rpt. 43, June 1968.

Vol. IV.--Sugar, Fruits, and Vegetables. Foreign Agr. Econ. Rpt. 44, June 1968.

Vol. V.--Oilseeds, Oil Nuts, and Animal and Vegetable Oils. Foreign Agr. Econ. Rpt. 47, Aug. 1968.

Japan's Food Demand and 1985 Grain Import Prospects. Foreign Agr. Econ Rpt. 53, June 1969.

World Demand Prospects for Agricultural Exports of Less Developed Countries in 1980, Foreign Agr. Econ. Rpt. 60, June 1970.

World Demand Prospects for Wheat in 1980 with Emphasis on Trade by Less Developed Countries. Foreign Agr. Econ. Rpt. 62, July 1970.

Growth in World Demand for Feed Grains: Related to Meat and Livestock Products and Human Consumption of Grains, 1980. Foreign Agr. Econ. Rpt. 63, June 1970.

World Demand Prospects for Cotton in 1980 with Emphasis on Trade by the Less Developed Countries. Foreign Agr. Econ. Rpt. 000, Jan. 1971.

World Demand Prospects in 1980 for Bananas. Foreign Agr. Econ. Rpt. 69, Feb. 1971.

Copies of these reports may be obtained upon request to the Division of Information, Office of Management Services, U. S. Department of Agriculture, Washington, D. C. 20250.

Additional reports are being developed on the following as part of the overall research project: World demand prospects in 1980 for rice; total grains; citrus fruits; and coffee, tea, and cocoa; the Japanese grain-livestock economy; and world agricultural import barriers. Publication of these reports will be announced.
