ALTERNATIVE FUTURES FOR WORLD FOOD IN 1985, VOLUME 2, WORLD GOL MODEL SUPPLY-DISTRIBUTION AND RELATED TABLES. By Anthony Rojko, Patrick O'Brien, Donald Regier, Arthur Coffing, and Linda Bailey; Foreign Demand and Competition Division; Economics, Statistics, and Cooperatives Service; U.S. Department of Agriculture. Foreign Agricultural Economic Report No. 149.

ABSTRACT

Detailed supply-distribution tables from the world grain-oilseeds-livestock (GOL) projections model are presented. The projections to 1985 rest on a number of alternative assumptions about world economic growth, trade, and food policy conditions.

Under most of the alternatives tested, the world has sufficient capacity--whether measured in terms of physical potential or economic feasibility--to meet the grain and overall food needs of an expanding, more affluent population at real prices somewhat above base 1970 levels but below 1972-75 highs. However, the projections indicate that regional food distribution problems are likely to persist. Moreover, the alternative assuming lower grain yields and deteriorating climate and weather suggests the possibility of serious pressures on resources and higher prices for grain imports by developing countries.

As a whole, the developing countries' grain imports are projected to increase faster than imports in the rest of the world; 1985 imports are projected to range from 49 million tons under the alternative assuming a continuation of present agricultural and trade policies, to 71 million tons under the high import demand alternative. Recent import levels have been 30-35 million tons. Rising demand for meat and livestock products is projected under all alternatives. Growth in the commercial sectors of the world meat economy ranges from one-third to one-half above 1970 base levels.

Key words: Projections, agriculture, world food problems, economic model, grains, oilseeds, livestock products, trade.

FOREWORD

The Economics, Statistics, and Cooperatives Service (ESCS) is working on a continuing basis on projections of changes in world export markets, population, income, and resource and environmental constraints and of their impact on the U.S. agricultural sector. The affected U.S. variables include production, consumption, trade, prices, farm costs, and farm incomes.

Major components of the projections program are world, regional and country projections of production, demand, trade, and prices of major commodities important in agricultural trade. These projections are useful in evaluating the broad issues of future world food prospects.

The world projections are made within the framework of a mathematical world grain-oilseeds-livestock (GOL) model. The model is designed to capture the main economic relationships of the three groups of commodities and to test the impact of different economic and policy assumptions on projected quantities and values.

Projections of U.S. agricultural exports generated by the GOL model are not official ESCS projections of U.S. trade in agricultural commodities. Rather, they are presented to aid users in evaluating the impact of different assumptions on world trade.

Results of the GOL model are being presented in this volume in the form of principal model input and output tables. Together with the other GOL volumes, this volume provides the model documentation. The GOL model is one analytical tool used along with other ESCS computer programmed mathematical models for analyzing future food and agricultural trade prospects.

PREFACE

This study reports on one phase of an ongoing research effort aimed at generating and maintaining up-to-date price, production, consumption, and trade projections for agricultural commodities in the major countries and regions of the world. This study assesses alternative world food prospects through the use of a mathematical model of the world's grain-oilseeds-livestock economies (GOL model).

The study is being published in several volumes. Volume 1 is the analytical report, which summarizes the GOL projections to 1985. Volume 2, the present report, contains detailed country and regional supply-distribution tables and related price and growth rate tables. Volume 3 will describe and present the mathematical equations used in the GOL model. Volume 4 will be a users' manual. Volume 2 is expected to be updated periodically to maintain a current set of alternative projections.

The research effort requires substantial ongoing teamwork from members of the Commodities Program Area working with others in the Foreign Demand and Competition Division of the Economics, Statistics, and Cooperatives Service (ESCS). Others in ESCS working in econometric model development have also participated. Under the overall direction of Anthony S. Rojko, significant inputs have been made by Donald Regier (livestock and derived feed), Patrick O'Brien (grains), Arthur Coffing (oilseeds), Robert Barry (rice), Myles Mielke (dairy), and Linda Bailey. Several people have helped to develop the computer programs, beginning with Francis Urban in the early stages, Hilarius Fuchs during the main development stage, and Fenton Sands and Martin Schwartz in the later stages. The contribution of Angela Wray in editing the materials in this volume is also acknowledged.

While it is impossible to cite all the individuals in FDCE who contributed, special recognition is given to Wayne Denny, Gene Hasha, John Link, and John Parker for their contribution to the productivity aspects of the developing world. Recognition is also acknowledged to James B. Johnson, Leroy Quance, and Allen Smith for their contribution to the U.S. sector.

ALTERNATIVE FUTURES FOR WORLD FOOD IN 1985

VOLUME 2, WORLD GOL MODEL SUPPLY-DISTRIBUTION AND RELATED TABLES

by

Anthony Rojko, Patrick O'Brien, Donald Regier,
Arthur Coffing, and Linda Bailey

DESCRIPTION OF DATA AND COMPUTER RUNS

The world grain-oilseeds-livestock (GOL) model projects the world pattern of production, consumption, trade, stocks, and prices for the major grain, oilseed, and livestock commodities for up to 28 major countries or regions. The model is designed to quantify the impact of alternative assumptions regarding population, income growth, the projected year, policy variations, and productivity growth rates. The mathematical relationships underlying the model can also be modified to evaluate additional alternatives.

This volume contains detailed projections resulting from six alternatives of the GOL model. The assumptions and conditions which define each alternative are discussed on page 3. Following that discussion is a narrative summary highlighting the results of the projections to 1985, together with summary tables.

The detailed balances of supply and utilization for the six alternatives can be divided into four categories--grains, oilmeals, dairy products, and meats. The grain category includes wheat, coarse grains, rice, and total grains. Oilmeals include the meal fraction of nine different oilseeds (soybean, cottonseed, sunflowerseed, flaxseed, peanut, rapeseed, sesameseed, copra, and palm kernel) plus fishmeal. The dairy category consists of milk, butter, and cheese. The meats category includes beef, pork, mutton, and poultry. For alternatives I, II, and III, each detailed commodity balance is followed by a price table.

The supply-utilization balances were standardized to the extent possible for ease of computer operation. Area, where applicable, is listed in 1,000 hectares, yield in metric tons per hectare, and production, feed use, food use, total use, and trade are in 1,000 metric tons.

An additional column on the supply-utilization tables computes the world share of production for each region covered in the model. The world totals do not include production and use for the centrally planned countries, for which only international trade was projected.

Prices are shown following the individual commodity balances, and contain columns for the projected supply price, demand price, variable levy, and trade price. While the first three are expressed either in U.S. dollars or in local currency, the trade price is always on a dollar-equivalent basis. The projected prices are real prices expressed in 1970 dollars.

The price margins between regions and between commodities may appear to be less than fully consistent. This situation developed because in construction of the model, an attempt was made to use as many regularly quoted prices as possible.

Where not available, regional price data were based on export unit values. As a result, because of major quality differences among commodities, some interregional and intercommodity margins are larger or smaller than would be expected based on transportation costs alone.

Although prices are generated, the model's objective is not to forecast prices, but to indicate price pressures that are consistent with the supply-utilization levels projected under each alternative. In that context, alternatives I, II, and III define high, low, and medium levels of price pressures. It was felt these three were sufficient to give the reader insights as to the price projections of the model. Thus, price projections for alternatives I-A, IV, and IV-A are not shown.

In the cereals category, coarse grains include corn, barley, oats, rye, and sorghum. Some grains that were not included are millet, minor sorghum crops, and mixed grains. Feed demand is estimated directly from the livestock production equations. The food demand equations may also reflect small quantities of feed, since some of the minor livestock categories, such as horses and rabbits, are not covered in the livestock production equations. For those regions where a livestock sector is not modeled, feed demand is estimated directly from population and income. Though containing waste, seed, and industrial uses, estimates for food and other uses are based on population and income projections. Imports and exports are net trade projections for a country and thus abstract from temporary price margins and quality differences which permit some regions both to export and import. This is especially important within the EC-6, where intraregional trade is large.

Wheat includes all forms of wheat, including durum. Rye is included with coarse grains rather than with wheat. In the rice table and in total grain aggregates, rice data are in milled equivalent.

Total grains is simply the aggregation of the coarse grains, wheat, and rice detail as generated and used in the model. Only the yield column and the percentage of world supply are recalculated.

Oilmeal includes oilcake and meal from nine of the common oilseeds. The data also include fishmeal. The area data include only area where a response to changes in meal prices might be expected, and thus do not include area for cottonseed, tree crops, or fishmeal. One consequence of this is that yield data as shown are extremely variable. The two usage columns are not completely definitive, and some food use may be included in the feed category and vice-versa. The difference between production and total usage results because only imports are projected for the centrally planned regions.

The projections for dairy products are made to (1) estimate feed demand and (2) provide a very broad outline of the industry. Thus, coverage is limited to the developed world and even then only a minimum amount of detail is shown. The four dairy tables consist of a total milk production table and three utilization tables covering fluid milk, butter, and cheese. Trade levels are projected only for butter and cheese. Egg production is estimated only to project feed demand.

Projections for production and utilization of meats are largely limited to commercial markets. Unlike the regional aggregations for dairy, however, the production regions for meat involved include countries other than developed countries. The United States is listed as both an importer of low-quality beef and an exporter of high-quality beef. Exports of specialty meats are not considered in the model. In other regions, meats were projected only on a net trade basis.

Production and trade for all meats are on a carcass-weight basis. Total meat production, utilization, and trade are the sum of the individual tables.

In addition to the basic balances of commodity supply and utilization, other data are presented for each alternative to aid in evaluating the projections. These include a series of commodity balances which present the projections in terms of per capita levels, and growth rates for both the aggregate and the per capita projections. Also included are base and projected income (private consumption expenditure) on a per capita basis, population, and feed-to-meat conversion factors, as well as growth rates for population and income, and base 1970 data, actual and per capita.

This volume offers full geographic and commodity detail for the projections presented in volume 1 of this series. The descriptive and tabular summary material that follows is reproduced from that volume as a guide to the meaning and significance of the computer runs of projection detail comprising most of this volume. The summary material is aggregated from earlier computer runs according to projection alternative. Therefore, the projection detail in the computer runs presented here does not necessarily regenerate the numbers shown in the summary. The data in the world GOL model is being continuously updated and the model itself adjusted. Tabulations of projection detail following the summary tables are reproduced from the most recent projection runs executed with the GOL model.

The assumptions underlying the major alternative sets of projections presented here can be summarized as follows:

- Alternative I assumes a modified continuation of trends and basic agricultural and trade policies around the world. International trade is somewhat restricted by protectionist national economic policies, but not all trade-restrictive goals are met.
- Alternative I-A assumes the successful implementation of alternative I's protectionist policies in the developed countries and slowed economic growth in the developing countries.
- Alternative II assumes high income growth rates that generate substantially higher levels of world import demand.
- Alternative III quantifies the effects of generalized slowed income growth and low world import demand in conjunction with alternative I-A's restrictive trade policies.
- Alternative IV tests out the case of selectively higher productivity in the developing countries in the context of high income growth rates and strong world import demand.
- Alternative IV-A tests out the case of generalized higher productivity in the developing countries in the context of high income growth rates and strong world import demand.

In addition, several parametrics were run as aberrations to alternatives I and II to evaluate the impact of secular climatic and cyclical weather patterns on longrun yield and production levels.

SUMMARY OF PROJECTION RESULTS TO 1985

The results of the world grain-oilseeds-livestock (GOL) model presented in this report point up the strong interrelationships tying together the world's

grain, oilseed, and livestock sectors and their importance in shaping future world food balances. The mathematical model reported on in this study makes alternative projections to 1985 of production, consumption, trade, and prices of grains, oilseeds, and livestock products. Projections are also included for grain and oilseed area and yield, and for grain food and feed use. Projected values are contrasted with 1970 base period levels, as well as with 1973-75 levels.

The projections rest on a number of alternative sets of assumptions, designed to evaluate the impact of different combinations of world economic, trade, and food policy conditions. These alternative sets of assumptions trace out the impacts of a continuation of recent policies, of a shift toward high world import demand with high income and more liberalized trade, of a shift toward low import demand and more stringent trade restrictions, and of different levels of agricultural productivity in developing countries.

The alternative tracing out the effect of a continuation of recent policies around the world and the alternative assuming more liberalized trade policies and higher income growth are considered as having higher likelihoods of occurring than the alternative assuming slowed income growth and low import demand. The alternative tracing out the effects of low income growth and more restricted trade demonstrates, however, the importance of world prosperity to world trade.

All of the alternatives discussed above assume the absence of any major climate change, either favorable or unfavorable, that could change future grain and oilseed yields substantially. The 1975 drought in the Soviet Union, the 1976 drought in Western Europe, and recent weather problems in the United States have reactivated concern about the possibility of deterioration in the world's climate and its implications for future world food production. Separate computer runs were made to estimate the effect of lower grain yields on the world food supply-demand balance and resulting pressure on resource availability. Separate runs were also made to capture the effects of more frequent weather-induced crop shortfalls than occurred in the two decades prior to 1972; results of these runs were used to determine the production needed to build adequate stocks in "good" years to maintain consumption in "bad" years.

Grain

Under most of the alternatives tested, the world has sufficient capacity--whether measured in terms of physical potential or economic feasibility--to meet the grain and overall food needs of an expanding, more affluent population at real prices somewhat above base 1970 levels, but below 1972-75 highs.

However, the projections indicate that regional food distribution problems are likely to persist. Moreover, the alternative that assumes lower grain yields indicates that deteriorating climate and weather could pose serious, possibly generalized, pressures on resources and prices.

The developed countries as a group--particularly the United States, Canada, and Australia--have the capacity to increase grain production to meet projected foreign and domestic demand. Their own use of grain is forecast to increase by over a third by 1985, largely because of increased demand for products from grain-fed livestock. Foreign demand for their grain is likely to increase at least 75 percent, and possibly as high as 125 percent, as a result of both stronger feed demand in the richer importing countries and stronger food demand in the developing countries.

Under the policy continuation alternative, the exporters as a group would probably face problems of restraining production, given the assumption that the

major exporters continue to adapt their production policies to changing global supply and demand conditions. Production in the United States and Canada in particular was assumed to adjust downward so as to prevent the accumulation of large, price-dampening stocks and upward so as to take advantage of growth in world import demand--be it either long-term growth related to population and income changes, or short-term growth related to production shortfalls.

Grain deficits in the developed importing countries as a whole are forecast to increase significantly, possibly doubling by 1985 from base 1970 levels under the high import demand alternatives. Substantial growth in grain import demand is expected in Japan. Growth in Western Europe will depend considerably on the European Community's Common Agricultural Policy, and possible expansion of the Community membership or the adoption of similar policies by other European countries. Imports by Eastern Europe are expected to expand significantly, and the Soviet Union's imports are projected to be about or somewhat higher than the 6- to 8-million-ton level of the USA-USSR agreement negotiated in 1976. Under the high import situation, the Soviet Union's net grain imports exceed 11 million tons.

Grain imports of the developing countries as a whole are projected to increase appreciably faster than imports in the rest of the world; with 1985 imports ranging from 49 million tons under the policy continuation alternative to 71 million tons under the high import demand alternative. This range compares with 18 million in the 1970 base and recent levels of 30-35 million tons. Wheat comprises the bulk of the grain imported; the largest purchasers are the more affluent countries of North Africa, the Middle East, and East Asia, as opposed to the poorer countries of Central Africa and South Asia. The developing countries' 1985 imports could be as low as 34 million tons, however, under the increased productivity alternative. Boosting growth in productivity by only the .4 or .5 percent per year implied in expanded use of physical inputs and agricultural technology could well lower the developing countries imports below base 1970 levels--while keeping per capita consumption growth at roughly twice the annual trend rate of .4 percent registered in the 1960's and early 1970's.

Projected increases in grain yields to 1985 differ widely by individual grain and by region. Overall growth, however, is expected to exceed the rates of the last half decade and to approach or exceed--depending on the model alternative--the rates of the 1950's and 1960's. Growth is postulated on the assumption that developed countries expand use of existing technologies. Yield increases are also likely in the developed countries as existing but still unadopted technology spreads to the less advanced countries of the temperate zone.

The largest potential for yield increase is in coarse grains--particularly corn. However, continued emphasis in many of the developing countries on improvements in wheat and rice yields, and on allocation of the most productive resources to the production of wheat and rice, are likely to keep increases in coarse grains yields well below increases in other grains.

Livestock

Strong and rising demand for meat and livestock occurs under all alternatives. Growth in the commercial sector of the world meat economy ranges from one-third to one-half above the base period level. In no case is a decline projected in world per capita consumption of meat. It stagnates in developing countries under the effects of low income, but rises in all other alternatives.

Important considerations bear on this outlook. While meat consumption is bolstered by growth in income and population, national policies for production and trade also determine meat consumption levels and world trade patterns. Present policies imply continuation of high domestic prices and import barriers in the most important meat-consuming regions. Heavy balance-of-payments disbursements on fuel imports, feed inputs, and on finished meat imports may cause restrained meat consumption.

The commercial sector of the world meat economy holds to historical patterns in the projections. The United States and the European Community (EC) continue to be the major producing and consuming areas, with Canada, Mexico and Central America, and Other Western Europe sharing in the growth. Japan becomes a major world consumer. Argentina and Oceania remain the principal suppliers of long-distance meat to Western Europe, which continues to be a major importer as well as producer. If the EC were to lower meat import barriers, world trade would be stimulated, leading to higher levels of world production, expanded consumption even in the EC, and possibly exportation of ordinary beef by the United States (in addition to high-quality beef). Western Europe, rather than the United States, could thus measure as the world's largest meat importer.

Feed costs are projected to be higher relative to livestock product prices than they were in 1969-71. Thus, the degree of expansion in meat production will hinge on greater efficiencies in the structure of production and marketing.

The GOL model also indicates the crucial importance of developments in the feed-livestock sectors. The extent to which the developed countries expand grain-fed livestock sectors, and the developing countries build up such sectors, will be a major determinant of grain prices and hence of world food problems in 1975. With a moderate rise in consumption of grain-fed livestock products in the developed countries and a continuation of largely cereal-based human diets in the developing countries, the projections indicate that exporters would have no problem meeting both food and feed demand for grain at reasonable prices. Even if grain demand grows more rapidly as a result of modest increases in feed use in developing countries, production should be sufficient to keep real grain prices below the high 1972-74 levels.

Grain prices could be pushed up substantially, however, if income in the lower income developed countries grew rapidly and generated stronger demand for livestock products. If Japan or the poorer countries of Western Europe were to adopt U.S. grain feeding techniques, grain prices could rise substantially as food demand bids against feed demand. Strong economic growth concentrated in the developed countries and the higher income developing countries could make it difficult for the poorer developing countries to raise per capita grain consumption levels faster than .3 to .4 percent a year.

Oilseeds

Demand for oilmeals will continue to grow with increased production of livestock and livestock products. Under the policy continuation alternative, commercial demand increases 3.6 percent annually on a global basis. The increase under the high income alternatives is more rapid. To match these increases in demand, supply increases are projected under all alternatives. The largest supply changes are projected for the United States and Brazil, where soybean production continues to expand. Trade in oilmeals continues to expand rapidly, in some cases doubling the rate of production expansion. One implication is that both producers and consumers will tend to become even more dependent on world markets.

Real oilmeal prices are projected to advance significantly. Under the high import demand alternative, the rise is comparable to the increase projected for pork prices and only a little higher than the increase projected for coarse grain prices.

Because of the diversity of crops involved, it is harder to generalize with respect to yields of oilseeds and, consequently, oilseed meals. At one extreme, sunflower yields have increased rapidly in many areas of the world. At the other, soybean yields have been constant or have trended upward only slightly. Probably the greatest yield potential lies in peanut production in South Asia and West Africa. However, since soybeans account for the largest share of world meal production, and since efforts to improve yields have been largely unsuccessful, the area component will continue to account for a significant portion of the total increase in production.

Climate and Weather

To estimate the impact of possible longrun changes in climate, reductions in growth in yields of 5 to 15 percent were postulated for the major areas of the world subject to wide weather fluctuations historically. The impact under the lower income and consequently lower demand alternative is moderate; the major producers, particularly exporters, are able to expand area, thus offsetting slower growth in their own yields and slower production growth in regions where area expansion is more difficult.

However, lower grain yields combined with the higher demand alternative could pose serious problems. The major developed exporters would need to expand area considerably, but only at higher costs per unit of output and reduction of area in other crops. The higher grain prices projected could discourage some growth in the livestock industry. For example, a move to more restrictive trade policies and a return to higher levies in both meat and grains could be expected in much of Western Europe. The net effect, however, would be to increase U.S. coarse grain exports from 62 million tons under the original high demand alternative to 77 million tons given lower grain yields and high demand. The increase in U.S. exports of wheat is considerably less--from 50 million tons to 54 million tons. The assumption of the poor climate scenario would result in reduced U.S. yields in the present major wheat belt and some shift in wheat production eastward to areas with more moisture. However, this move would be limited because of competition from coarse grains and soybeans. Harvested area in the United States for total grains and soybeans could be as high as 118 million hectares. This corresponds to a record in excess of 120 million hectares harvested in the 1975/76 period. Harvested area in Canada, Australia, and Argentina by 1985 would also approach or exceed recent highs on a regular basis.

World trade in beef and pork is also affected under the poor climate scenario. This scenario assumes low demand and recourse to trade protectionist practices. An increase in variable levies in the EC and limitations in Japan would make the market for low grade beef in the United States more attractive than that in Europe. However, Argentina and Australia would not be able to take full advantage of the high world prices of meat. Beef production in the United States, under the lower yield alternative, would be expected to shift to a greater extent east of the Mississippi--accelerating a trend that has been occurring in the last two decades. The United States could be a major exporter of pork as world prices of pork would likely increase substantially more than prices of beef.

For the developing countries, imports of grain increase to 82 million tons, compared with 70 million under the higher yield assumption. This import gap could

not be met without massive food aid. Slowed production growth and high import demand, however, would be incompatible with high income growth and low agricultural productivity. Thus, a concerted effort to boost indigenous grain production probably would take place, thereby reducing the import gap.

Implications for the United States

Under each alternative, the U.S. share of world grain and oilseed exports is higher in 1985 than it was in 1961-71. The same is true for the U.S. share of world livestock product imports.

Under the policy continuation alternative, increased export availabilities in other major grain exporting countries reduce the U.S. share of the world grain market below 1972-74 highs. U.S. exports of wheat, coarse grains, and rice total 77 million tons in 1985, compared with an average of 40 million tons in 1969-71 and 73 million tons in 1974-76. The U.S. share of world grain exports is 54 percent, which compares with 45 percent in 1969-71 and as high as 60 percent in recent years.

U.S. wheat exports, projected at 34 million tons, are substantially above the 18-million-ton average of 1969-71 and the 30-million-ton average of 1972-74. Coarse grain exports, at 40 million tons, are double the 1969-71 average but marginally below the highs of 1972-74.

Under the high import demand alternative, U.S. grain exports in 1985 are 116 million tons, accounting for some 60 percent of world grain exports. Coarse grain exports increase to 62 million tons, with U.S. corn exports to livestock feeders in Western Europe accounting for about half of the increase because of the more liberalized trade policies assumed. Growth in world feed grain import demand under this alternative is almost twice the annual rate of the alternative assuming a continuation of current policies. The U.S. share of this larger market increases at the expense of the other major exporters because of greater U.S. production capacity. U.S. wheat exports increase to 50 million tons, with imports by the developing world accounting for most of the gain. The low-income developing countries account for about three-fourths of the 15-million-ton increase in wheat exports to the developing countries. These countries might find it difficult to purchase such amounts under the high import demand situation unless a greater proportion of imports are concessional than under the policy continuation assumption.

Model Format

The model's mathematical relationships are specified to capture the interaction of production, consumption, trade, and prices of grain, oilseed, and livestock products. Basic inputs include population and income growth rates, income elasticities, direct and cross demand and supply price elasticities, supply variables, and assumptions about underlying economic trends and policy constraints.

Where possible, the model incorporates resource constraints and provides for changes in trends in yield growth, as well as changes in consumer preferences, such as shifts toward livestock products or shifts out of feed grains into wheat and rice products. The model covers the world in up to 28 country or regional aggregations for grains and 14 for the commercial, trade-oriented meat economies.

Commodities quoted on the following basis:

Wheat--U.S. No. 1 Ordinary Protein, Gulf Ports quoted in base

Coarse grain--U.S. No. 2 Corn Yellow, Gulf Ports

Rice--Thai White, 5 percent Broken, FOB Bangkok

Oilmeal--U.S. Soybean Meal, 44 percent protein, Gulf Ports

Beef--U.S. Cow Beef, imported frozen, 90 percent lean Chicago

Pork--U.S. hams, shoulders, canned, average import unit value, carcass weight

-- means less than 0.5 million tons

--- means projections not shown.

1/ Estimated gross exports--shown to indicate trade volume.

2/ Medium population, historical income growth rates, low land bound. Represents potential rather than expected or most likely.

3/ Sum of the 96 countries left out are PRC and many minor countries.

4/ Defined as low-income countries, generally a broader definition than developing market economies.

5/ Projections that resulted from the trade study.

6/ Developing countries.
