Social networks, consumer beliefs and nutrition behavior: Theory and empirical evidence for Germany

Christian H.C.A. Henning and Nana Zarnekow
Department of Agricultural Economics, University of Kiel
chenning@ae.uni-kiel.de, nana.zarnekow@ae.uni-kiel.de

Selected Poster prepared for presentation at the Agricultural & Applied
Economics Association's 2013 AAEA & CAES Joint Annual Meeting,
Washington, DC, August 4-6, 2013.

Social networks, consumer beliefs and nutrition behavior: Theory and empirical evidence for Germany

Christian H.C.A. Henning and Nana Zarnekow
chenning@ae.uni-kiel.de, nana.zarnekow@ae.uni-kiel.de

Problem

- Circa 30% of total health expenditures are related to nutrition based morbidities in Germany
- Medical Facts regarding nutrition and health are very well understood
- Potential for functional food (food with health implications)
- Nutritional behavior can only very limited be controlled by scientific knowledge (consumer information, training) or incentives (fat tax)
- Unhealthy nutrition is much more behavioral and less a medical phenomena

Theoretical Model

Health-beliefs and preferences for functional food: A new approach

Consumers are fundamentally uncertain about the technological relation between food characteristics (E) and implied Z-goods (Z), namely health, thus, consumers form beliefs, \hat{A} . Applying a linear approximation of the approach implies linear utility functions at the micro and macro stages:

$$\begin{aligned} V(Z) &= \sum_k \beta_k Z_k + \beta_p^z P_z \\ U(E) &= \sum_i \alpha_i X_i^E + \alpha_p^E P_E \quad \Rightarrow \quad \alpha_i = \sum_k \tilde{\alpha}_{ki} \beta_k \end{aligned}$$

Belief-up-dating Model

A simple linear Belief-up-dating Model

- Ideosyncratic shocks bias individual learning of the underlying food-health technology
- Information exchange with local social neighborhood reduces bias and thus increases efficiency of learning
- communication is organized in social networks:

$$\begin{aligned} \tilde{A}_i &= t_{ii} \tilde{A}_i^0 + (1 - t_{ii}) \cdot \sum_j \hat{t}_{ij} \tilde{A}_j \\ \text{with: } \hat{t}_{ij} &= \frac{t_{ij}}{(1 - t_{ii})} \end{aligned} \quad (1)$$

Rewriting eq.(1) in matrix notation:

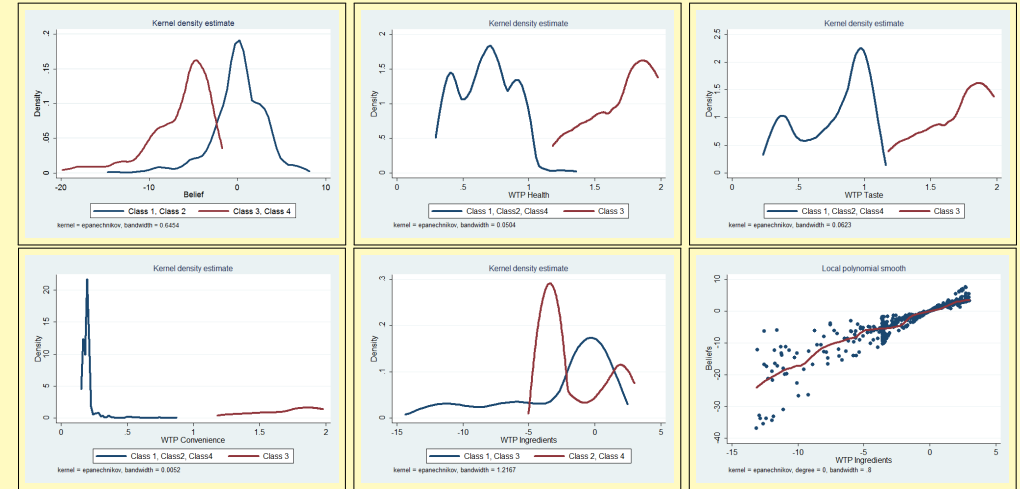

$$\tilde{A} = [I - (1 - t_{diag}) \hat{T}]^{-1} \cdot t_{diag} \cdot \tilde{A}^0 \quad (2)$$

$M = [I - (1 - t_{diag}) \hat{T}]^{-1} t_{diag}$ is the matrix of network multiplier corresponding to the Hubbell-Index.

- A_i = beliefs after communication
- A_i^0 = agent i 's initial beliefs after private up-dating
- t_{ii} = own control (weight for the own belief)
- $(1 - t_{ii})$ = influence or communication field of other agents

Empirical Model

Using own unique social and medical survey data of 1000 probands collected within the Focus-project we test our theory applying a two-stage latent class estimation of macro and micro food preferences. In particular, the approach allows a statistical testing of the impact of peer group network effects on consumer beliefs, preferences and nutrition behavior.

Results

- We derive a new consumer theory including explicitly consumer's fundamental uncertainty regarding consumption technology.
- In our theory consumers form beliefs on how specific consumer good characteristics translate into relevant z-goods which determine consumers' utility.
- Applied to demand for functional food consumers form beliefs regarding the impact of functional ingredients on health.
- Consumers up-date beliefs via communication learning organized in social networks. Accordingly, EGO-centric network structures are determinants of individual consumer beliefs and hence preferences for functional food.
- Empirically estimate consumer beliefs based on an unique own choice experiment data set.
- Further, we identify EGO-centric network parameters as relevant determinants of individual consumer beliefs controlling explicitly for latent homophily.
