Yield Response to Nitrogen with Time Trend and Nonnormality

Frederic B. Ouedraogo* and B. Wade Brorsen**

* PhD. Student ** Regents Professor & Susan Jacques Chair, Oklahoma State University

Objective

- ⊕ Estimate the profit maximizing level of nitrogen with a nonnormal stochastic plateau and a time trend
- ⊕ Determine whether the increased cotton yield is due to increased efficiency of nitrogen use or increased ability to use nitrogen

Motivation

- ☞ Cotton has shown increased yields over time and recommended levels of nitrogen per bale have decreased
- ☞ Past literature on crop yield assumed normality of error terms while evidence exists that yield has non zero skewness
- ☞ Stochastic plateau model with time trend enables investigation of yield response to both physical inputs and unobservable structural changes.

Econometric Model

The following stochastic plateau model is used:

$$(1) y_{it} = \min(\bar{\alpha}_0 + \bar{\alpha}_1 N_{it}, \bar{P} + v_t) + u_t + \varepsilon_{it}$$

y_{it} : observed yield in year t for i^{th} treatment

$\bar{\alpha}_k = \alpha_k + \delta_k T, k = 1, 2$ and $\bar{P} = P + \delta_3 T$,

T = time proxy; $v_t \sim \text{Beta}(0, \theta)$ and $u_t \sim N(0, \sigma_u^2)$ are plateau and intercept year random effects, and $\varepsilon_{it} \sim N(0, \sigma_\varepsilon^2)$ is the equation error term.

Methods

1. Maximum likelihood methods

- ☉ The mixed stochastic plateau model is used with beta distributed plateau random effects
- ☉ SAS PROC NLMIXED is used to fit the model and assign the beta distribution to the plateau error term
- ☉ A Gaussian quadrature approximation is used to maximize the likelihood integrated over the random effects

2. Bayesian estimation methods

- ☉ All the random effects are normally distributed except the plateau random effect, which is beta distributed
- ☉ A noninformative prior is used so that the main purpose of using Bayesian methods is to avoid convergence issues associated with maximum likelihood
- ☉ SAS PROC MCMC is used to estimate the parameters

Results and Conclusions

Parameter	MLE	SE	Bayesian	SE
α_0	325.2	.007	452.0	35.20
α_1	1.04	.000	-1.5	0.200
δ_1	10.7	.000	9.6	1.30
δ_2	2.0	.000	0.2	0.01
δ_3	28.4	.000	14.0	3.54
P	736.8	.008	982.9	2.15

- ⊕ The impact of time trend is more accentuated in the plateau than in the other parameters.
- ⊕ The increase in the ability to use more nitrogen explains more of the increase in yield over time, but all parameters increase over time.
- ⊕ Convergence is still a problem in both the maximum likelihood and in the Bayesian models.
