# Factors Determining Quality of Agricultural Biotechnology Patents

Anwar Naseem and Rohit Singla

Department of Agricultural Economics, McGill University, Canada

## INTRODUCTION

- ❖ Quantitative valuation of technology patents is challenging as there exist no market data, such as licensing or other indicators of commercialization. In the absence of such data, firm decision to patent given technologies must be made on the less objective qualitative factors that can, at best, only give a probabilistic estimate of market success. In recent years, the bibliometric data has enabled researchers to understand better the quality of patents through citation analysis.
- ❖ The *objective* of this study is to examine factors affecting quality of agricultural biotechnology patents. The analysis considers agbiotech patents belong to academia as well as industry.
- ❖ A majority of the literature on agbiotech patenting focused on quality of university/academic level patents. These studies are Barham, Foltz, and Kim (2002), Foltz, Kim, and Barham (2003), Buccola and Xia (2004) and Xia and Buccola (2005). There are only few studies that analyzing both academic and industry patents. Heisey, King, and Rubenstein (2005) and Graff and Zilberman (2004) discussed and analyzed the patents filed by university and public sector inventors, biotech entrepreneurs and corporations; they found systematic differences in their attributes.
- ❖ There is no study that focused on examining factors affecting quality of agricultural biotechnology patents. This study examines the potential factors determining a patent quality using data at patent level.

## METHODS

- ❖ In the empirical model, we assume forward citations as the dependent variable representing patent quality. Many studies have provided evidence of a strong positive relationship between value of a patent and the number of forward citations it received. In the past, other measures of patent quality have been also used in the literature. Nevertheless, forward citation is used more frequently, and has been established itself as the best indicator of patent value. The forward citations variable is assumed to have negative binomial distribution because the forward citations variable is highly skewed. Many studies have modeled forward citations variable in a negative binomial regression framework because of the skewed nature of the variable (Hu, Bian, and Wang 2008; Sterzi 2012; Lissoni and Montobbio 2012; Harhoff et al. 1999; Sapsalis, van Pottelsberghe de la Potterie, and Navon 2006). Negative binomial regression is usually employed for over-dispersed count outcome variables.
- ❖ More specifically, we estimate the following negative binomial model:
$$E(CRECEIVE | X) = \exp(\beta_0 + \beta_1 CLAIMS + \beta_2 CMADE + \beta_3 GENERAL + \beta_4 ORIGINAL + \beta_5 NOINV + \beta_6 FWDAPLAG + \beta_7 BCKGTLG + \beta_8 SELFCTLB + \beta_9 SECDLWBD + \sum_i \alpha_i ASSIGNEE_i)$$
- ❖ The definitions and summary statistics of the variables (except *ASSIGNEE*) used in the model are presented in the next table. *ASSIGNEE* is a categorical variable that represents whether a patent holder is public/private organization and whether that organization in the U.S, or in other countries.

## DATA/PARAMETERS

- ❖ The dataset is constructed by merging Agricultural Biotechnology Intellectual Property database (developed by ERS USDA) and National Bureau of Economics Research (NBER) patent citations data. King and Schimmelpennig (2005) and their collaborators constructed a similar database to describing quantity, quality and technical composition of patent stocks of six large agbiotech firms. The agbiotech patent data comprises of a set of utility patents issued by the US Patent and Trademark Office (USPTO) between 1976-2000. The utility patents were identified as relevant to agricultural biotechnology and biological processes in food and agriculture.

## RESULTS

Summary Statistics of major variables

Variables	Definitions	Min	Max	Mean	Standard Error	Q1	Median	Q3	Mode	Std Dev	Skewness

## SUMMARY & CONCLUSIONS

- ❖ The number of claims an agbiotech patent has, and number of citations it is making have positive and significant effect on its quality.
- ❖ The coefficient on generality index was found to be positive and significant, which suggests that the more general a patent in its applications, the higher its quality.
- ❖ The coefficient on originality index was found to be negative and significant.
- ❖ Self-citations were also found to be negatively affecting the patent quality.
- ❖ Forward citations lag has a positive impact; however, backward citations lag has negative impact on a patent value.
- ❖ Apart from this, the patents registered by U.S. private firms were found to have the highest value followed by the patents from U.S. government, non-U.S. private firms
