BASIC STATISTICS OF THE NATIONAL INVENTORY OF SOIL AND WATER CONSERVATION NEEDS

INTRODUCTION

The National Inventory of Soil and Water Conservation Needs was conducted by the U. S. Department of Agriculture (USDA) cooperating with the land-grant colleges and other Federal, State, and local agencies. Its purpose, as stated in U. S. Department of Agriculture Secretary's Memorandum 1396, issued April 10, 1956, was to provide the Department and other land-use planning and conservation agencies with "reasonable estimates of the magnitude and urgency of the various conservation measures needed to maintain and improve the country's productive capacity for all the people." The Department and its cooperating agencies have "constant need and use for information that can be gained only through a national inventory of soil and water conservation needs."

This volume contains the basic statistics of the Inventory. It includes data about four major aspects of the Nation's agricultural land, as follows: (1) Land capability, by class and subclass; (2) land use, actual in 1958 and expected in 1975; (3) conservation treatment needed on land in each land use; and (4) small watershed projects needed.

The part of the Inventory dealing with land capability and land use (reported in Part I) and with conservation needs (Part II) is concerned specifically with all rural land outside of Federal ownership—privately owned land, Indian land, and land owned by States, counties, and municipalities. This information, with the timber resources review,¹ gives the Department basic information about all the land on which the USDA is authorized to carry on conservation and land use programs.

Since effective watershed treatment requires consideration of all land—whether private or public, rural or urban—draining to a stream, the watershed inventory (Part III) includes Federal land and all water areas as well as the non-Federal land covered in the rest of the Inventory.

Soil surveys of statistically selected sample areas in every county began in 1957 and were completed in 1960. Statistical laboratories processed the resulting data and expanded them to represent the entire acreage included in the Inventory. Ten States did their own processing, and the rest was done at Cornell University and Iowa State University. Conservation Needs Committees in each county and State then made their estimates according to procedures established by a national Inventory committee, made up of representatives of eight agencies of the Department of Agriculture.

¹U.S. Forest Service, 1958. Timber resources for America's future. U.S. Department of Agriculture, Forest Resource Report No. 14. Washington, D.C. 713 pp., illus. A preliminary review draft of the report was released in October 1955.

Data on all items included in the Inventory are summarized for each of the 50 States, Puerto Rico, and the Virgin Islands, for each of 10 economic regions, and nationally for the 48 mainland States and for the 50 States.

Basic policies

The Inventory was conducted according to the following policies established in Department Memorandum 1396:

"1. A National Inventory of Soil and Water Conservation Needs will be made and kept current by the Department of Agriculture. This Inventory will be developed for each county in the United States and for appropriate subdivisions of the Territories. The goal for initial completion will be three years. The Forest Service has recently completed an intensive survey of the Nation's timber resources. County estimates for forestry, insofar as is possible, will be developed from this timber survey and other available forest resource information.

"2. The Department agencies concerned with land use, soil and water conservation and the management of land resources which are to co-operate in this endeavor are: Agricultural Conservation Program Service,² Agricultural Research Service, Commodity Stabilization Service,² Federal Extension Service, Farmers Home Administration, Forest Service and Soil Conservation Service. Other agencies of the Department will be called upon where they can make a contribution. The Soil Conservation Service is hereby assigned responsibility for leadership.

"3. A Department Soil and Water Conservation Needs Committee, comprised of one representative from each of the agencies named in paragraph 2, will be established. This committee, under leadership of a chairman from the Soil Conservation Service, will aid in the development and review of proposed procedures, furnish guidance in the cooperative effort, and make periodic reviews of progress for the information of the participating agencies.

"4. A Soil and Water Conservation Needs Committee will be established in each State or Territory. Its membership will consist of representatives who work within the State or Territory for the Department agencies named in paragraph 2. The Soil Conservation Service representative will serve as chairman. The State Conservationist of the Soil Conservation Service will invite representation on the committee from the Land-Grant College, the State

²Reorganization of the Department in 1961 replaced these agencies as participants by the Agricultural Stabilization and Conservation Service, Economic Research Service, and Statistical Reporting Service.

Forester, and other appropriate State agencies and groups who may be able to provide assistance and useful data. The State or Territorial committee will develop a plan for making the Inventory, and will submit it to the Administrator of the Soil Conservation Service for review and consideration of the Department Committee and the Assistant Secretary, Federal-States Relations.

"5. Data will be developed separately for privately owned and publicly owned land. The Soil Conservation Service will be responsible for collecting basic physical data on soil and water on non-federally owned lands. The Forest Service will be responsible for the adequacy of the physical data on forestry on non-federally owned lands. The Forest Service and other land management agencies will be responsible for making the Inventory on lands under their jurisdiction.

"6. Cooperation of State and local agencies, organizations, and groups concerned with soil, water, forest, range and wildlife conservation, utilization, and management will be actively solicited in the development and review of the Inventory. The Department of Agriculture will also seek and encourage the cooperation of other Federal agencies, responsible for land management activities, in the development of data which can be utilized in the National Inventory of Soil and Water Conservation Needs."

Basic economic framework

The national Conservation Needs Inventory Committee decided in 1956 on basic economic assumptions to guide State and county committees in their estimates. State committees, in turn, refined or added to these assumptions as they applied to each State. The national assumptions that form the economic framework of the Inventory were stated as follows in the Policy and Procedure for Development of National Inventory of Soil and Water Conservation Needs:

"1. There will be a population increase in the United States for the period 1953 to 1975 from 152 to 210 million. The projected increase in population and moderate rise in per capita consumption of farm products will increase requirements in 1975 to about 40 percent above 1953. Since production is in excess of utilization,

an increase in farm output of around 30 percent will meet projected requirements.

"2. Total acreage of crops, including cropland pasture, will be about 6 percent greater in 1975 than in the period 1951-53.

"3. With the expected cropland acreage and fuller adoption by farmers of available technical knowledge in crop production, it appears that market demands in 1975 can be met if certain adjustments are made. Significant shifts will be required in the crops grown. There will also be need for shifts in major land uses, including such changes as the clearing, draining, and irrigating of land for cropland and pasture, reforestation of less productive croplands, and loss of agricultural lands to nonagricultural uses.

"4. The projected increase of population and growth of the Nation's economy will expand the demand for timber products. The 1975 demand for wood products in total (industrial wood and fuel wood) may be as much as 30 percent above 1952 consumption. . . To meet these timber requirements, more intensive management of all available commercial forest land will be needed. It will be imperative that commercial forest lands presently nonstocked or poorly stocked be restored to productive conditions. The more critical problems will relate chiefly to increasing the growth of softwood sawtimber and the improvement of productivity of farm and other small forest-land ownerships.

"5. Demands for recreation facilities and for wildlife will increase more rapidly than the increase of population.

"6. To meet the water requirements of the increased population, which will be accompanied by expansion of industry, intensified agriculture, and other uses, there will be increased competition for available water supplies. This will result in an expansion of water-resource development.

"7. Land owners and operators will be expected to spend no more on conservation measures than will yield a reasonable return to their capital and labor.

"8. The public will provide expenditures for soil and water conservation measures in addition to expenditures by land owners and operators when deemed necessary in the public interest to prevent serious permanent damage to soil and water resources."

SUMMARY OF FINDINGS

The non-Federal agricultural land covered by the National Inventory of Soil and Water Conservation Needs includes 76 percent of the total land area of the 48 mainland States and 87 percent of Hawaii but only 1 percent of Alaska (table 1). It amounts to 1,448 million acres in the U.S. mainland and 1,452 million acres in the total United States.

Privately owned land, including Indian land, amounts to 71 percent of the U.S. mainland, or 1,351 million acres. State and local government land amounts to 5 percent, or 97 million

acres. The latter includes State parks and wildlife refuges, school-grant land under lease or permit for farming and grazing, recreational and watershed areas, and other non-Federal public facilities.

Land capability and land use

The land of the United States has a wide range of climatic and soil conditions and hence a wide range in its capability for agricultural use. As a basis for determining existing land use and

conservation needs, soil surveys were made of sample areas in all counties except a few in completely built-up metropolitan areas. The surveys total between 25 and 30 million acres and represent a true cross-section of the Nation's land resources and conditions.

The data on soils were used to classify the land into eight land-capability classes that show the intensity of soil problems. Under this system of classification, land in classes I through III is suitable for regular cultivation and a wide range of other uses; land in class IV is marginal for cultivation; and land in classes V through VIII is generally suitable for noncropland uses only. All classes except class I are divided into subclasses by four dominant problems that limit land capability. These problems are erosion, excess water, unfavorable soil conditions, and adverse climate. Class I has no special problems that limit its use.

The inventory data (tables 2-13 and 15-27) show that about a fifth of the total inventory acreage is in each of classes II, III, VI, and VII. The other fifth is divided among classes I, IV, V, and VIII.

Forty-four percent (637 million acres) of the inventory acreage is suitable for regular cultivation (classes I-III), 2 percent being in class I. Twelve percent (169 million acres) is marginal for cultivation (class IV). The other 44 percent (642 million acres) is generally unsuitable for cultivation (classes V-VIII).

Of the land suitable for regular cultivation, 60 percent (373 million acres) is being cultivated, and 37 percent (238 million acres) is being used for pasture or woodland. Of the land in class I, 76 percent (27-1/2 million acres) is being cultivated.

Of the land marginal for cultivation, 29 percent (49 million acres) is being cultivated.

Of the land generally unsuitable for cultivation, 4 percent (25 million acres) is being cultivated. Most of the rest is in pasture and woodland.

Changes in land use

Survey data from the sample areas, expanded to the total Inventory acreage and adjusted to take into account information from the 1954 Census of Agriculture, the timber resources review, and other sources showed the following acreages in each of the major agricultural uses (tables 2-13) in the 48 mainland States in 1958:

Cropland	447,399,000 acres	31 percent
Pasture and range	484,716,000 acres	33 percent
Forest and woodland	449,651,000 acres	31 percent
Other land	66,271,000 acres	5 percent

The Inventory committee in each county estimated changes in land use expected to take place by 1975. These estimates were based on knowledge of current local trends in land use in relation to soil and land-capability data for the county

and on certain uniform assumptions as to population growth and economic trends from 1953 to 1975.

A summation of these county-by-county estimates indicates that changes in land use in the 17-year period would affect large acreages but make only small net changes in the land devoted to each use.

Cropland acreage is expected to decline slightly. Although the committees estimated that 42 million acres of 1958 cropland would be converted to other uses by 1975, only about 31 million acres of new cropland is expected to come into cultivation from other uses. The result will be an expected net decline of only 11 million acres, or nearly 3 percent, in total cropland.

Most of the expected decline in cropland will occur east of the Mississippi River, with the largest decrease—about 13 percent—in the Northeast. Major increases in cropland acreage are expected in Florida, Iowa, Minnesota, South Dakota, and most of the West.

In contrast, the acreage of pasture and range is expected to show a net increase of about 3 percent, or 12-1/2 million acres. Most of the increase is expected to be in the Great Plains, the Mountain States, and in the South.

Forest and woodland acreage is expected to decrease about 2 percent or 10 million acres, mainly as a result of the conversion of noncommercial woodlands in the Southern Plains to pasture or cropland. A significant increase in forest and woodland acreage is expected in the Northeast.

The biggest net shift in land use will be in land going out of agriculture to urban and other nonfarm uses. A total of more than 20 million acres shifting to urban and built-up areas, Federal land, water, and other uses, will be only partially offset by about 5 million acres of Federal and other land coming into private agriculture. The net loss in private agricultural land will be slightly more than 15 million acres in the 17-year period.

Conservation needs

While much has been done in solving soil and water conservation problems on the Nation's agricultural land, the Inventory shows that much remains to be done. Approximately two-thirds of all the privately owned cropland, grazing land, and woodland in the 48 mainland States still needs some kind of conservation treatment.

The Inventory Committee in each county estimated the acreage in each land use that was adequately treated and that needing treatment for each of several types of conservation problems. The problems for cropland and "other land" are primarily problems of conserving the soil resource. So the estimates of needs were based mainly on land-capability classes and subclasses.

The problems on pasture and range and on forest and woodland are problems of conserving the plant cover as well as the soil resource. So

the estimates of needs for these land uses were based on the actual conditions of the plant cover.

The acreage needing treatment in each land use takes into account the treatment needed for land expected to come into that use from other uses by 1975.

Cropland.—A summation of the county-by-county estimates shows that of the total cropland in the 48 mainland States, 62 percent (272 million acres) needs treatment while 38 percent (164 million acres) does not.

Of the cropland not needing treatment, 17 percent (28 million acres) is class I land, which has no conservation problems limiting its use; and 83 percent (136 million acres) is land already adequately treated.

Susceptibility to erosion is the most widespread dominant problem on cropland. Cropland with this dominant problem makes up 53 percent (234 million acres) of the total cropland and 60 percent (161 million acres) of the cropland needing treatment. Much of the land with erosion as the dominant problem has a secondary problem of excess water, unfavorable soil, or adverse climate. Sixty-nine percent needs treatment.

Excess water is the dominant problem on 22 percent (94 million acres) of the total cropland—also 22 percent (60 million acres) of the cropland needing treatment. Much of this wet cropland also has a secondary problem of erosion or unfavorable soil. Sixty-four percent of it needs treatment.

Unfavorable soil in the root zone is the dominant problem on 13 percent (55 million acres) of the total cropland—also 13 percent (36 million acres) of the cropland needing treatment. Much of this cropland with a root-zone problem has a secondary problem of erosion or excess water. Sixty-five percent of it needs treatment.

Adverse climate is the dominant problem on 6 percent (24 million acres) of the total cropland—5 percent (14 million acres) of the cropland needing treatment. Erosion is a secondary problem on most of this cropland. Fifty-eight percent of it needs treatment.

Pasture and range.—Nearly three-fourths (73 percent), or 364 million acres, of non-Federal pasture and range in the U.S. mainland needs conservation treatment and improvement (table 30). More than 280 million acres of this land is in the 17 Western States.

Of the land needing treatment, 20 percent (72 million acres) needs establishment of new cover, 30 percent (107 million acres) needs improvement of existing cover, and 50 percent (185 million acres) needs only improved water management or improved protection from overgrazing, fire, erosion, or encroaching brush and weeds.

In addition, undetermined acreages of chaparral, pinyon-juniper woodland, and grassy forested areas that were classified as forest and woodland in this Inventory and that are also grazed may need conservation practices for the improvement of the vegetation for grazing.

Forest and woodland.—More than half (55 percent), or 241 million acres, of the non-Federal forest and woodland of the U.S. mainland needs conservation treatment (table 31). In addition, still larger acreages (which overlap with the acreage needing treatment and with each other) need better protection from fire, insects and disease, and animals.

Of the forest and woodland needing treatment, 30 percent (69 million acres) needs establishment of timber stand, 65 percent (160 million acres) needs timber-stand improvement, and 5 percent (12 million acres) needs erosion control.

Fifty-seven percent (252 million acres) of all non-Federal forest and woodland, needs better protection from fire; 47 percent (207 million acres) from insects and disease; and 19 percent (82 million acres) from damage by browsing and grazing animals.

Other land.—Of the other land in agricultural use, 17 percent (10 million acres) needs conservation treatment of some kind (table 32).

Small watershed project needs

The inventory of small watershed project needs covered soil and water problems and needs that could not feasibly be met by action of individual land owners or through large-scale works on major rivers. These are primarily problems of water management, both agricultural and non-agricultural, such as flood prevention, erosion control, drainage, irrigation, water supply, wildlife habitat, and recreational development.

These problems require project action that can be effected only through formal organizations that have legal status in the State. All land and water areas in the United States except Alaska are included in this part of the Inventory. With the exception of a few areas where there are no known problems of water management, watersheds were delineated to a size suitable for projects under the Watershed Protection and Flood Prevention Act and similar authorities—250,000 acres or less.

In the development of this part of the Inventory, other Federal and State agencies concerned with water resource development and use cooperated with the Department of Agriculture.

The Inventory committees delineated 12,711 individual small watersheds in the U.S. mainland, having a combined area of 1,922,592,000 acres. The committees determined that projects of various sorts, many of them multiple-purpose, are needed in 8,323 of these watersheds covering slightly more than 1 billion acres (table 33).

Reduction of floodwater and sediment damage is the most extensive problem occurring in these watersheds. It affects more than 125 million acres in nearly 1 million farms and ranches and an undetermined number of towns and cities. Project action is required to deal with the problem on nearly 63 million acres subject to floods in 6,343 watersheds.

Project action is needed to protect nearly 24 million acres of land in 4,651 watersheds from critical erosion damage.

Projects are needed in 3,931 watersheds to drain 45 million acres and in 2,611 watersheds to irrigate 15 million acres.

The need for recreational development was recognized in 1,955 watersheds and for other nonagricultural water supply in 823 watersheds. In view of developments that have increased interest in these project purposes since the In-

ventory was undertaken, these estimates are now considered to represent only a fraction of actual needs. Furthermore, many counties and several States did not inventory these needs. For these reasons, this part of the Inventory is considered incomplete and does not reflect the true magnitude of nonagricultural water management problems.

Part I. LAND CAPABILITY AND LAND USE

County Conservation Needs Inventory Committees determined present (1958) land use by land-capability class and subclass and estimated changes in land use likely to occur by 1975. These data are summarized by States, by economic regions, and nationally in tables 1 through 27.

The basic data on land capability and land use were obtained from soil surveys of sample areas made by the Soil Conservation Service. The sample-area data were expanded to equal the inventory acreage of each county. Other basic information supplied by the Forest Service and other State and Federal agencies was used in making final estimates of the acreage in each land use.

The Inventory acreage

The inventory acreages reported in these statistics are summations of county inventory acreages.

First, State committees determined a base figure for each county by subtracting the area of Federal land (except cropland) from the total land area as given in the 1954 Census of Agriculture. The Federal land acreages were obtained from the appropriate Federal agency.

Then, using data obtained in the soil survey adjusted as necessary, each county committee obtained its county inventory acreage by subtracting from the base figure the acreage of urban and built-up areas and of water areas smaller than 40 acres and streams less than 1/8 mile wide. (Larger water areas are excluded in all Census figures of land areas.) The base figures and resulting inventory acreages were later revised to agree with 1959 Census land area figures as they became available.

Basic data on soil and land use

The basic data on soils and land use were obtained from soil surveys made by the Soil Conservation Service.

Randomized samples were selected in every county by the statistical laboratories at Cornell University and Iowa State University. The sample areas were located on county base maps with a scale of 1 inch equals 2 miles, or larger. The maps showed the boundaries and symbols of land-resource areas and soil conservation districts. Watershed boundaries were shown where known or were added later. If there was Federally owned land in a county, its boundaries were shown on the maps.

The standard size of sample areas was 100 acres in the 13 Northeastern States and 160 acres in the others. In sectionized country, quarter sections were designated as sample areas. No attention was paid to farm boundaries.

The basic sampling rate was 2 percent, the rate that would provide data of an acceptable degree of reliability in a county of 250,000 to 500,000 acres. As standard procedure, the statistical laboratories selected two separate

sets of sample areas in each county, each set making up about 2 percent of the county.

Calculation of the relative sampling error for a 2-percent sample made up of 160-acre units indicates that on the average the standard error for any item that covers 1 percent of a State of about 63,000 square miles will be plus or minus 5.1 percent. Following are calculated standard errors for items occupying different percentages of such a State and of the U. S. mainland:

Extent of item (percent of area)	Standard error for	
	State	U. S. mainland
1	5.1	0.9
5	2.3	0.4
10	1.6	0.3
25	1.1	0.2
50	0.8	0.15
75	0.5	0.1
100	0.0	0.0

The laboratories used the following procedure in selecting sample areas: the county, or land-resource area within the county, was divided into blocks, or "strata," which were then further divided into equal-sized sample areas. One sample area was selected at random from each block for each of the two sets of samples.

The laboratories outlined on each county map one set of samples in red and the other in blue. From this map sample area boundaries were transferred to the aerial photographs on which the mapping was to be done.

In counties larger than 250,000 acres, where one set of sample areas provided adequate data, only the set outlined in red was mapped. In smaller counties, the "blue" set was also used in order to maintain a satisfactory degree of reliability. No substitution or intermingling of the two sets was permitted.

All possible use was made of existing soil-survey information. For counties with recently completed surveys no additional field work was needed.

On sample areas not already mapped, soil surveys were made on the regular aerial photograph field sheets at the scale locally used. In partially mapped counties, surveys of sample areas were made according to the legend in use in the county. Insofar as possible, all new mapping was done according to legends that could be used in the standard soil survey.

In mapping the sample areas, urban and built-up areas were classified as to land use only.

Federal land identified on the sample-area map generally was not mapped. If mapped, it was measured separately. If the Federal land included cropland farmed under lease or permit and if a total acreage of Federal land could be obtained, that falling in sample areas was mapped. On Indian land, the Bureau of Indian Affairs assisted in getting survey information.

All existing soil maps of sample areas were field checked before use. The map was revised if the soil survey was not adequate or if the land use shown did not agree with present conditions on the ground or with the Inventory definitions.

Land use was mapped on all sample areas. The condition at the time of the mapping was shown; no attempt was made to predict the intent of the operator. Land use was designated as: Cropland, pasture and range, forest and woodland, and other land.

In measuring sample-area maps, each individual soil-mapping unit was measured separately so the data could be combined by land-capability units or other desired interpretive groupings.

The soil and land use data from the sample areas were then expanded by a statistical laboratory to give figures representing the total inventory acreage of each county.

Land-capability data

The soil data from the sample areas were interpreted in terms of land capability according to standards in use locally by the Soil Conservation Service in the National Cooperative Soil Survey and in soil conservation district operations.

Expanded data on land capability were provided to county conservation needs inventory committees for use in estimating changes in land use and determining conservation needs.

Estimates of land use change were made by land-capability units, the grouping of soils that are essentially alike in potential for agricultural use, plant growth, and response to management.

Conservation needs for cropland were determined by land-capability subclass, a grouping of land-capability units having the same dominant problem limiting use and requiring conservation treatment. Land capability units were not summarized above the county level.

Land-capability classes are still broader groupings according to intensity of hazards or limitations in use. These classes aid in evaluating need for changes in land use and requirements for conservation treatment.

Land-capability data by class and subclass are summarized in tables 2 through 13 and tables 15 through 27.

The land-capability classification

The land-capability classification³ is one of a number of interpretive groupings of soils made primarily for agricultural purposes. As in all interpretive groupings the land-capability classification begins with the individual soil-mapping units. In this classification the arable soils are grouped according to their potentialities and

limitations for sustained production of the common cultivated crops that do not require specialized site conditioning or site treatment. Non-arable soils (soils not suitable for longtime sustained use for cultivated crops) are grouped according to their potentialities and limitations for the production of permanent vegetation and according to their risks of soil damage if mismanaged.

The land-capability classification provides three major categories: (1) Unit, (2) subclass, and (3) class. The land-capability unit is a grouping of soils that are adapted to the same kinds of common cultivated crops and pasture plants and that require similar systems of management for these crops.

The land-capability subclass is a grouping of land-capability units having similar kinds of limitations or hazards. Four kinds of limitations or hazards are recognized: (1) Erosion hazard, (2) excess water or wetness of soil, (3) unfavorable soil in the root zone, and (4) adverse climate.

The third and broadest category in the land-capability classification places all the soils in eight land-capability classes. The risks of soil damage or the limitations in use become progressively greater from class I to class VIII. Soils in the first four classes are capable under good management of producing adapted cultivated field crops, pasture or range plants, forest trees, or other adapted plants. Soils in classes V, VI, and VII are suited to the use of adapted native plants. Some soils in classes V and VI are also capable of producing specialized crops, such as certain fruits and ornamentals, and even field and vegetable crops under highly intensive management involving elaborate practices for soil and water conservation. Soils in class VIII do not return on-site benefits for inputs of management of crops, grasses, or trees.

Land-capability classes, subclasses, and units are defined in terms of specific soil properties and other conditions applicable to each survey area. Following are generalized definitions of the land-capability classes as used in the National Inventory of Soil and Water Conservation Needs.

Land-capability classes

Land suited for regular cultivation and other uses

CLASS I - These soils have few or no conditions that limit their use. They can be safely cultivated without special conservation treatment.

Soils in this class are suited to a wide range of plants and may be used safely for cultivated crops, pasture, range, woodland, and wildlife. The soils are nearly level and erosion hazard (wind or water) is low. They are deep, generally well drained, and easily worked. They hold water well and are either fairly well supplied with plant nutrients or highly responsive to inputs of fertilizer.

³Klingebiel, A. A. and P. H. Montgomery, 1961. Land-capability classification. U. S. Dept. Agr., Agr. Hdbk. 210. Washington, D. C. 21 pp.

The soils in class I are not subject to damaging overflow. They are productive and suited for intensive cropping. The local climate is favorable for growing many of the common field crops. Soils in class I that are used for crops need ordinary management practices to maintain productivity—both soil fertility and soil structure.

CLASS II - These soils have some natural condition that limits the kinds of plants they can produce or that calls for some easily applied conservation practice when they are cultivated.

Soils in this class require careful soil management, including conservation practices, to prevent deterioration or to improve air and water relations when the soils are cultivated. The limitations are few and the practices are easy to apply. The soils may be used for cultivated crops, pasture, range, woodland, or for wildlife food and cover. The soils in this class provide the farm operator less latitude in the choice of either crops or management practices than soils in class I. They may also require special soil-conserving cropping systems, soil conservation practices, water-control devices, or tillage methods when used for cultivated crops.

CLASS III - These soils have more serious or numerous limitations than those in class II. They are more restricted in the crops they can produce or, when cultivated, call for conservation practices more difficult to install or keep working efficiently. They may be used for cultivated crops, pasture, woodland, range, or for wildlife food and cover.

Limitations of soils in class III restrict the amount of clean cultivation; timing of planting, tillage, and harvesting; choice of crops; or a combination of these items. The limitations may be natural ones—such as steep slope, sandy or shallow soil, or too little or too much water. Or the limitation may be erosion brought on by the way the land has been used.

Land suitable for occasional cultivation and for other uses

CLASS IV - These soils have very severe limitations that restrict the kinds of plants they can grow. When cultivated, they require very careful management, and conservation practices are more difficult to apply and maintain. In humid areas, they are suitable for occasional but not regular cultivation; in subhumid and semiarid areas, crops fail in low-rainfall years. Soils in class IV may be used for crops, pasture, woodland, range, or for wildlife food and cover.

Many sloping soils in class IV in humid regions are suited for occasional but not regular cultivation. In subhumid and semiarid regions soils in class IV may produce good yields of adapted cultivated crops during years of above average

rainfall; low yields during years of average rainfall; and failures during years of below average rainfall. During the low-rainfall years the land must be protected even though there can be little or no expectation of a marketable crop.

Land generally not suitable for cultivation but suitable for other uses

CLASS V - These soils have little or no erosion hazard but have some condition impractical to remove that limits their use largely to pasture, range, woodland, recreation, water supply, or wildlife food and cover.

Soils in this class have limitations that restrict the kind of plants that can be grown and that prevent normal tillage of cultivated crops. They are nearly level but some are wet, are frequently overflowed by streams, are stony, have climatic limitations, or have some combination of these limitations.

CLASS VI - These soils have severe limitations that make them generally unsuited for cultivation and restrict their use largely to pasture, range, woodland, recreation, water supply, or wildlife food and cover.

Physical conditions of soils placed in class VI are such that it is practical to apply range or pasture improvements, if needed, such as seeding, liming, fertilizing, and water control with contour furrows, drainage ditches, diversions, or water spreaders. Depending upon soil features and local climate the soils may be well or poorly suited to woodland.

Some soils in class VI can be safely used for the common crops provided unusually intensive management is used. Some of the soils in this class are also adapted to special crops such as sodded orchards, blueberries, etc., requiring soil conditions unlike those demanded by the common crops.

CLASS VII - These soils have very severe limitations that make them unsuited for cultivation and that restrict their use to pasture, range, woodland, recreation, water supply, or wildlife food and cover with careful management.

Soil restrictions are more severe than those in class VI because of one or more continuing limitations that cannot be corrected, that make them unsuited for common cultivated crops. Physical conditions of soils in class VII are such that it is impractical to apply such pasture or range improvements as seeding, liming, fertilizing, and water-control measures such as contour furrows, ditches, diversions, or water spreaders. Depending upon the soil characteristics and local climate, soils in this class may be well or poorly suited to woodland.

CLASS VIII - These soils and landforms have limitations that prevent their use for commercial plant production and that restrict their use to

recreation, water supply, or wildlife food and cover with careful protection.

Soils and landforms in class VIII cannot be expected to return significant on-site benefits from management for crops, grasses, or trees, although benefits from wildlife use, watershed protection, or recreation maybe possible. Badlands, rock outcrop, sandy beaches, river wash, mine tailings, and other nearly barren lands are included in class VIII.

Land-capability subclasses

Subclasses are groups of land-capability units within classes that have the same kinds of dominant limitations for agricultural use. Some soils are subject to erosion if they are not protected, while others are naturally wet and must be artificially drained if cultivated crops are to be grown. Some soils are shallow or droughty or have other soil deficiencies. Still others are in areas where climate limits their use. The four kinds of limitations recognized at the subclass level are: Risks of erosion, designated by the symbol "e"; wetness, drainage, or overflow "w"; root-zone limitations "s"; and climatic limitations "c." The class and subclass provide the map user information about both the degree and the kind of limitation. There are no subclasses in class I.

Subclass e, erosion, is made up of soils in which the susceptibility to erosion is the dominant problem or hazard in their use. Erosion susceptibility and past erosion damage are the major soil factors for placing soils in this subclass.

Subclass w, excess water, is made up of soils in which excess water is the dominant hazard or limitation in their use. Poor soil drainage, wetness, high water table, and overflow are the criteria for determining which soils belong in this subclass.

Subclass s, other unfavorable soil conditions in the root zone, is made up of soils in which the soil characteristics of the root zone are the dominant limitation in their use. These limitations are such factors as shallow soils, stoniness, low moisture-holding capacity, low fertility difficult to correct, and salinity or sodium.

Subclass c, climatic limitation, is made up of soils in which the climate (temperature and lack of moisture) is the major hazard or limitation in their use.

Limitations imposed by erosion, excess water, shallow soils, stones, low moisture-holding capacity, salinity or sodium can be modified or partially overcome and take precedence over climate in determining subclasses.

Where two kinds of limitation that can be modified or corrected are essentially equal, the subclasses have the following priority: e, w, and s. For example, in humid regions soils that have equal problems of erosion and excess water are placed in subclass e; soils having equal problems of excess water and root-zone limitation are placed in subclass w. In grouping soils of

subhumid and semiarid regions that have both an erosion hazard and a climatic limitation, subclass e takes precedence over subclass c, and in grouping soils with both root-zone limitations and climatic limitations, subclass s takes precedence over subclass c.

Data on present land use

Data on present land use are for conditions in 1958, the base date of the Inventory. They are based on expanded data from surveys of sample areas, adjusted as necessary to take into account information from other sources. The predominant use evident at the time of the survey was recorded without reference to previous history or to the operator's intentions. Land use was determined mainly by the kind of vegetation and the physical condition of the land. These criteria for determining land use differ in some respects from those used in other statistical studies of the U. S. Department of Agriculture and of other Federal and State agencies.

The State Conservation Needs Inventory committees provided each county committee with available statistical data on land use, including data from the 1954 Census of Agriculture and from the timber resources review published in 1958 by the Forest Service, which showed forest and woodland acreages as of 1954. More recent forest-survey information was available for some counties.

Each county committee considered both the expanded sample-area data provided by the Soil Conservation Service and the related statistical information provided by the State committee in arriving at the acreages it believed most accurately represented the 1958 land uses in the county. In the review of State summaries, the National committee had access to advance returns from the 1959 Census of Agriculture and required State committees to verify or explain significant differences from the Census.

Land use definitions

The following definitions of land use were used in the Inventory:

Cropland.—Land currently tilled, including cropland harvested, crop failure, summer fallow, idle cropland, cropland in cover crops or soil-improving crops not harvested or pastured, rotation pasture, and cropland being prepared for crops or newly seeded. Cropland also includes land in vegetables, fruits, and nuts including those grown on farms for home use. All tame hay (and also wild hay harvested east of the Mississippi) was included as cropland. Meadowland was considered as cropland when it had soil and water conditions capable of producing a hay crop in normal years, was used primarily for the production of hay harvested nearly every year, and was locally considered as cropland rather than as pasture or range. The hay could consist of either native or introduced species.

Irrigated cropland.—Cropland to which water is usually applied by artificial means.

The 1958 acreage includes only cropland which was irrigated in 1957. Irrigated cropland was recorded in the 17 Western States.

Pasture and range.—Land in grass or other long-term forage growth used primarily for grazing. Pasture and range includes grassland, nonforested pasture, wild hay harvested in the 17 Western States, and other grazing land with the exception of pasture in the crop rotation. It may contain shade trees or scattered timber trees with less than 10 percent canopy, but the principal plant cover is such as to identify its use primarily as permanent grazing land. Pasture (primarily of introduced grasses) was separated from range (or native grasses) in some States. This does not include extensive acreages in the following categories which are grazed: Chaparral, pinon-juniper woodlands of the West, and grassy forested areas with more than 10 percent tree canopy.

Forest and woodland.—(a) Land which has at least 10 percent canopy of forest trees of any size and capable of producing timber or other wood products or capable of exerting an influence on the water regime; (b) land from which the trees described in (a) have been removed to less than 10 percent canopy and which have not been developed for other uses; (c) afforested (planted) areas; and (d) chaparral areas.

In farms or operated for production of forest products.—Forest and woodland that is part of a farm, and all other forest and woodland that is producing or physically capable of producing usable crops of wood, is economically available now or prospectively, and is not withdrawn from timber utilization.

Other forest and woodland.—Forest and woodland not a part of a farm that is withdrawn from timber utilization by public agencies, corporations or private persons; is incapable of yielding usable wood products because of adverse site conditions; or is so physically inaccessible as to be unavailable economically in the foreseeable future. This includes forest land set aside for special uses other than timber production, such as State parks, monuments, natural areas, and game preserves.

Other land.—All agricultural land not classified as cropland, pasture and range, or forest and woodland.

In farms.—"Other land" within the boundaries of a farm, such as farmsteads, idle land and wildlife areas. "Idle land" includes land formerly used for crops or pasture, now abandoned and not yet put to some other use. A

"farm" is used here to mean a tract of land some part of which produces crops for more than the family's needs.

Not in farms.—"Other land" outside the boundaries of a farm, such as crossroad filling stations, rural nonfarm residences, country churches and school grounds, and rural nonfarm idle land.

Urban and built-up areas.—Land in cities, villages, and other built-up areas of more than 10 acres; industrial sites, railroad yards, cemeteries, airports, golf courses; the intensively used and built-up parts of shooting ranges and institutional and public administrative sites; and highways, public roads, railroads, and airports. The acreage of farmland inside city and village limits was included in the Inventory acreage.

Water areas.—Water areas smaller than 40 acres and streams and canals less than 1/8 mile wide. This acreage only is listed under "Water areas" in table 1; it was excluded from the Inventory acreage after the survey of the sample areas. (Larger water areas were already excluded from the total acreage.)

Expected changes in land use

After the estimates of present land use had been approved by the State Conservation Needs Inventory Committee, each County Committee estimated the changes in land use expected to occur in the county by 1975.

These estimates were made by considering separately the acreage of each land-capability unit currently in each land use. The resulting land use estimates were summarized by land-capability class and subclass, but not by land-capability unit (tables 2-13). Estimates of expected acreages for 1975 included Federally owned land scheduled for transfer into private ownership.

The estimates of changes in land use took into consideration the physical capabilities of land; present land use and trends in land use; expected demands on the land for agricultural, forest, and other products and services as reflected in the economic framework; and the need for farming systems that are economically feasible to farm owners and operators. It was recognized that demands on the land for agricultural production and other purposes as well as size of farm unit and other factors might tend to keep some land in uses not now considered most desirable from the standpoint of the land's physical characteristics.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from composite tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreage of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

Table 6. Land capability and land use in 1958, and expected shifts in land use in 1975--Corn Belt region summary^a

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

Table 8. Land capability and land use in 1958, and expected shifts in land use in 1975--Appalachian region summary^a

Because of rounding, some totals may not equal the sum of the items listed and data may not check exactly with other summary tables.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreage of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

^aThe total acreages of cropland, pasture and range, forest and woodland, and other land were compiled from computer tabulations by States.

Wild hay harvested from about 9 million acres of dry land generally was excluded from cropland and included in pasture and range; wild hay harvested from over 1 million acres of irrigated land in the West was included in cropland.

A considerable part of the idle cropland in Arkansas and adjoining States is used to some extent for grazing. Idle cropland is occasionally cultivated in the regular cropping system.

The acreage of cropland for Colorado includes much marginal and idle cropland in varying stages of reversion to grassland range.

The total cropland acreage for Kentucky excludes 1,722,000 acres of grassland that are infrequently cultivated; this acreage is included in total pasture and range.

Approximately 634,466 acres of county and secondary roads in South Dakota were included in urban and built-up areas. This acreage was deducted from pasture and range, where it was originally put, to make the figures comparable with figures for other States.

The total cropland acreage for Tennessee excludes 996,000 acres of grassland that are infrequently cultivated; this acreage is included in total pasture and range.

Part II. CONSERVATION NEEDS ON THE INVENTORY ACREAGE

Conservation needs for all land included in the Inventory were estimated in acres of each land use having conservation problems and in acres of each needing treatment and feasible to treat.

After arriving at final estimates of acreages in each land use in 1958 and changes expected to occur by 1975, local Conservation Needs Inventory Committees considered each land-capability unit and land use category separately and determined its conservation needs according to standards prescribed by the National and State Inventory committees.

For purposes of the Inventory, conservation needs were considered to be needs for "protection, use, maintenance, and improvement of the resources to best serve both private and public interest in providing adequate food, fiber, forest products, recreation, and wildlife resources now and in the future." Conservation needs were expressed in acres that require treatment in order to maintain production in line with national interests as interpreted from the economic framework set by the National and State Inventory committees. Consideration was given to regional and local conditions and to the needs of the people for family income. Areas plainly not feasible to treat within the economic framework were not included in the estimated needs, even though treatment might be desirable.

Since problems for cropland and "other land" are primarily problems of conserving soil, land-capability units were the basis for these estimates. The problems on pasture and range and on forest and woodland involve the conservation of plant cover as well as soil. The estimates for these land uses, therefore, were based on the actual condition of the plant cover in 1958 and were made with no direct reference to land-capability units.

Estimates of conservation needs for each land use took into account the acreage expected to come into that use by 1975 as well as the acreage already in that use and expected to stay there. For example, new pasture to be established on land now in cultivation would add to the need for establishment of plant cover on pasture land. Land to be brought into cultivation from pasture or woodland was classified along with present cropland according to its dominant conservation problem.

Cropland

Conservation needs on cropland were estimated in acres having problems that limit use, crop adaptation, or plant growth, or that interfere with tillage, planting, or harvesting operations. Acreages in each category were determined from data on land capability, and the proportions of each already adequately treated and of each needing treatment and feasible to treat were determined by the local Inventory committees.

The land-capability units were grouped according to the dominant problems that determine

subclasses, with subgroups indicating secondary problems. Five conditions were recognized, alone or in combination, making a total of 17 possible conditions and combinations of conditions:

No problems that limit use. — Class I land, which has no conservation problems except those that are related to the restoration and maintenance of fertility and tilth and that can be solved by methods generally used in the community.

Dominant (or secondary) problem of erosion. — Land on which water or wind erosion has occurred or will likely occur under the expected use.

Dominant (or secondary) problem of excess water. — Land on which excess water caused by a high water table or by temporary flooding prevents or limits the use of conservation cropping systems and practices.

Dominant (or secondary) problem of unfavorable soil. — Land on which an unfavorable soil condition in the root zone, such as salinity, sodium, acidity, low fertility, stoniness, shallowness to rock, or low moisture-holding capacity, limits root development.

Dominant (or secondary) problem of adverse climate. — Land on which extremes in either precipitation or temperature or both are the major problem and limitation on use.

Pasture and range

Conservation needs on pasture and range were estimated in acres needing treatment for problems related to the establishment and maintenance of plant cover. In some States estimates were developed separately for pasture and for range.

Acreages needing establishment of cover, improvement of cover, or protection of cover do not overlap, it being understood that establishment or improvement includes the necessary protection. Acreages for different kinds of protection, however, may overlap.

Establishment of vegetation. — The acreage expected to be converted from other uses into pasture and range, plus acreage in pasture and range in such poor condition in 1958 that it needed to be completely reestablished.

Improvement of plant cover. — The acreage on which the plant cover was inadequate in 1958 but which could be restored to satisfactory condition by improvement measures short of complete reestablishment.

Protection of plant cover. — The 1958 acreage needing protection from one or more of the following:

Overgrazing. — The acreage with inadequate plant cover that could be restored to satisfactory condition by the management of livestock or installation of supplemental water facilities.

Fire. — The acreage with serious fire hazards that could be protected by installation of fire-prevention measures.

Erosion. — The acreage of gullied or other seriously washed and windblown areas that needed control measures to prevent further deterioration.

Rodents. — The acreage with serious rodent damage that could be corrected by chemical, mechanical, or other measures.

Encroachment of woody and noxious plants. — The acreage on which encroachment of woody and noxious plants had destroyed or was threatening the grass cover and which could be protected by chemical or mechanical means. This acreage does not include any pasture on which woody and noxious plants would be eradicated in the establishment or reestablishment of pasture.

Water Management:

Excess water. — The 1958 acreage on which excess water prevented the establishment, maintenance, and use of desirable plant cover.

Water conservation. — The 1958 acreage on which desirable vegetation could be feasibly established or improved by water-conserving measures.

Forest and woodland

Conservation needs on forest and woodland were estimated in acres needing the development and management of the forest and soil resources. The estimates were based on the acreage of forest and woodland expected by 1975, taking into account anticipated changes in land use.

Forest land withdrawn from timber utilization or incapable of yielding usable wood products because of adverse site conditions or so physically inaccessible as to be unavailable economically in the foreseeable future was not considered in estimating conservation needs except that needing conservation measures for watershed protection, for wildlife or recreation or for the protection of adjacent productive forest and woodland.

There are no overlaps between (1) the acreage needing establishment of timber stand, (2) the acreage needing improvement of timber stand, and (3) the acreage needing control of erosion. The sum of these three is listed under the column "Needing treatment." The acreages of the other problems may overlap these three and one another.

Estimates were made for the following problems:

Establishment and reinforcement of timber stand. — This acreage is made up of three components: (1) Land expected to shift to forest and woodland from other uses by 1975 except the acreage that needed trees to check erosion and the acreage of shelterbelts and windbreaks; (2) land classified as forest and woodland in 1958 less than 10 percent stocked or stocked with unsatisfactory species; (3) land in forest and woodland more than 10 percent stocked in 1958 but needing reinforcement. Ordinarily this did not include any acreage with a canopy of 40 percent or more. The estimated acreage includes only the number of acres which the reinforcement

planting would equal in complete establishment. For example, if a total area of 50,000 acres needed reinforcement but it was estimated that the planting needed to accomplish this would be equal to only 35,000 acres of full-scale establishment, the 35,000 acres was the area included in the estimate.

Improvement of timber stand. — The 1958 acreage of forest and woodland on which stand-improvement measures were feasible under good management. Estimates were limited to acreages expected to return the cost of improvement investment within 15 to 20 years.

Protection of timber stand from:

Fire. — The acreage of forest and woodland which in 1958 was not receiving protection adequate to meet the fire situation in the worst years and under critical conditions.

Insects and disease. — The acreage of forest and woodland in 1958 not effectively protected from insect and disease outbreaks.

Animals, including rodents. — The acreage of forest and woodland which in 1958 was not receiving adequate protection from animals, including rodents, and on which protection was feasible under good management. The estimate includes the need for protection from domestic animals.

Erosion control. — The acreage expected to be planted to trees to halt erosion, plus the acreage of forest and woodland on which erosion-control and water-disposal measures were needed to check gullies, control sheet erosion, stabilize dunes and blow-outs, contain slides, and control logging-road and skid-trail erosion.

Establishment of shelterbelts and windbreaks. — The acreage on which windbreaks and shelterbelts were needed and feasible to influence wind current and thus reduce soil blowing, control snowdrifting, conserve moisture, and protect buildings, fields, gardens, and feedlots.

Improved naval stores methods. — Forest and woodland expected to be operated for naval stores production in 1975 that will need to be operated under improved naval stores methods.

Other land

Estimates of conservation needs for "other land" were made in the same way as for crop-land, using the same definitions of problems. The estimates shown in table 32, however, do not show subgroupings by secondary problems. Such estimates were made by county Inventory committees and summarized for the States but were not included in the national report.

In estimating acreages needing treatment and feasible to treat it was recognized that "other land" is not subject to the problems that accompany tillage and that some of the acreage has such a low potential for productive use that treatment is not economically feasible, and that problems on "other land" affecting nearby crop-land, pasture and range, or forest and woodland had already been considered in the estimates for those land uses.

Table 28. Conservation needs on cropland

[Because of rounding, some totals may not equal the sum of the items listed and data may not check exactly with individual State reports.]

Part III. WATERSHED PROJECT NEEDS

In addition to estimating needs for conservation that could be accomplished by private efforts or by individual cooperation with local, State, and Federal governments, the Conservation Needs Inventory surveyed the needs and opportunities for resource protection and development through voluntary group action in small watersheds.

The objectives of this phase of the Inventory were: (1) To determine the nature and extent of conservation and water development problems requiring group action in small watersheds, and (2) to determine needs for project-type action under the Watershed Protection and Flood Prevention Act (Public Law 566) or similar legislation. These estimates do not, however, preclude Federal or State assistance under other programs and authorities.

Problems in small watersheds were classified as follows: (1) Floodwater damage, including inundation or sediment damage on flood plains and associated erosion on contributing uplands; (2) agricultural water management, typified by drainage and irrigation; and (3) other rural water management problems, including stockwater, municipal and industrial water supply, fish and wildlife development, and recreational facilities.

Watershed inventory procedures

The watershed phase of the Conservation Needs Inventory was completed during the period 1958-61 for the 48 mainland States, Hawaii, Puerto Rico, and the Virgin Islands. Alaska is not covered in this part of the Inventory.

From base maps showing stream systems, State Inventory Committees subdivided each State or inventory area into watersheds of 250,000 acres or less, the statutory size limit for projects under Public Law 566. A total of 12,711 small watersheds or planning units were delineated in the U. S. mainland. Detailed mapping was not completed in parts of some states—notably Maine, Oklahoma, Oregon, and Texas—because of the clear absence of problems or infeasibility of project action.

For each delineated watershed, Conservation Needs Inventory committees estimated the total acreage of flood plain, the acreage of critical erosion areas that are primary sources of sediment, the acreage drained or needing drainage with group outlet facilities, and the acreage potentially irrigable on the basis of suitable soils and available water.

The committees then estimated the portions of these problem acreages that could not feasibly be protected, treated, or developed by individuals or groups without the assistance of organized soil conservation districts, watershed districts, drainage or irrigation districts, counties, or other local and State units of government authorized to sponsor watershed projects under Public Law 566. It does not follow, however, that project action would necessarily have to be taken under that authority.

Additional criteria for determining whether such assistance is needed were: that project measures would entail group action for installation and group benefits for justification and that they would not be clearly unjustified from an economic standpoint.

In many of the watersheds, Inventory committees found need for project action to deal with two or more of the problems under consideration. In these watersheds, multipurpose projects would logically result.

The committees estimated the acreages needing project action and the number of farms benefiting from project measures in each watershed for each major flood-prevention or water-management problem.

In addition to the usual State, regional, and national totals (table 33), watershed project needs were summarized by the 160 principal drainage basins and the 18 major drainage areas of the United States mainland and of Hawaii, Puerto Rico, and the Virgin Islands (map 1, table 34). Watersheds spanning State lines usually were reported as whole units by one State or the other.

Parallel statistical summaries (table 35) were also prepared according to the water resource regions (map 2) used recently by the Senate Select Committee on National Water Resources⁴ in its appraisal of national and regional water resource development needs.

Definitions

Following are definitions of special terms used in the watershed project needs inventory:

Watershed.—Any drainage area of not more than 250,000 acres that would be a feasible unit for dealing with flood prevention and water-management problems.

Watershed project problems.—Water-management problems within the scope of the Watershed Protection and Flood Prevention Act⁵ that cannot be solved by the individual actions of the people affected by them.

Acreage having problem.—The total acreage subject to the watershed project problem, even though it may have been solved already. For example, the acreage of land with flood-water damage problems includes all land naturally subject to flooding even though it may now have adequate protection. The estimates of acreages having each watershed project problem were provided by the Soil Conservation Service for non-Federal land and by the responsible agencies for Federal land.

Project action.—Cooperative action that can be effected only through formal organizations

⁴Report of the Senate Select Committee on National Water Resources. 87th Cong., 1st sess. Senate Report 29. 147 pp. 1961. Also 32 separate Committee Prints reporting special studies by or for the Committee.

⁵The kinds of problems that can be met through this Act are described in Small Watershed Projects Under the Watershed Protection and Flood Prevention Act, U. S. Department of Agriculture, PA 392. 14 pages, 1959.

having legal status in the State and with powers to negotiate contracts, levy taxes, make assessments or otherwise raise funds, and to disburse funds for the installation, operation, and maintenance of works of improvements. The principal benefits of project action are ordinarily off-site.

Acreage needing projects. — The acreage having the problem that cannot be adequately protected or treated by individuals without project action as defined above. This same acreage may also require assistance under other programs.

Farms benefiting. — The number of farms having some acreage with the problem that requires project action.

Floodwater damages. — Direct and indirect damages by floodwater to homes, industries, towns, agriculture, roads, bridges, recreational facilities, etc.

Sediment damages. — Damages due to deposition of sediment in stream and drainage channels or infertile outwash on flood plains, silting of reservoirs, swamping or impairment of drainage on flood plains, damage to water supplies, and similar effects of sediment deposits.

Flood-plain area. — Both main-stem and tributary flood plains in all watersheds.

Critical erosion area. — Critically eroding areas on uplands, such as gullies, logging roads, diversions, stream banks, etc., that are serious sediment sources and that can be controlled only through group action.

Drainage-problem area. — Areas of level or nearly level land that require adequate group outlets for removal of excess water not directly attributable to flooding. Includes areas presently drained.

Irrigable area. — Land that suffers from shortage of water during critical growing seasons and that is potentially irrigable on the basis of suitability of soil and availability of water. Includes areas presently irrigated.

Nonagricultural water management problems. — Inadequate supplies of water for domestic, livestock, industrial, recreational, or fish and wildlife purposes, or for sustaining low stream flows to reduce pollution or salt-water intrusion. These data are considered incomplete because some counties and States did not inventory these needs. Moreover, since the Inventory began there have been changes in demand for water for these uses and in legislative authorities for watershed projects.

Water supply development. — Locally recognized needs for inclusion in multipurpose projects of storage and facilities for municipal or industrial water supply, stockwater development, or rural domestic supply to meet existing demands in 1958.

Recreation development. — Locally recognized needs for inclusion in multipurpose projects of additional storage and facilities for recreational purposes under conditions and legislative authorities in effect in 1958.

Table 33. Watershed project needs by States and farm production regions

[Because of rounding, some totals may not equal the sum of the items listed and data may not check exactly with individual State reports.]
