#### LIVESTOCK-PRODUCTION UNITS, 1910 to 1961 1/

#### By Earl F. Hodges, Agricultural Economist Farm Production Economics Division Economic Research Service

#### LIVESTOCK-PRODUCTION UNITS

The balance between livestock production and the feed supply is of national concern during periods of both feed surpluses and feed shortages. Livestock-production units are an effective means of measuring the balance between livestock production and feed consumption. These units also provide a basis for estimating the approximate amount of feed that may be needed at any time. In the index series of livestock-production units, the annual output of each of the principal livestock products is multiplied by a factor determined by dividing the feed consumed per unit of production by the feed consumed per year by one milk cow, 2/ thus converting livestock products to a common denominator. Converted to these units, livestock production can be related statistically to feed supplies and requirements as needed in many types of economic research.

The livestock-production unit series has followed more closely than has the animal unit series  $\underline{3}$ / the trends in feed consumption (fig. 1). The livestock-production series appears to reflect more accurately than the animal unit series the overall effect on feed consumption of changes in feed efficiency, substitution of feed for other farm resources, restricted feeding, inventory changes, and feeding of livestock to heavier or lighter weights.

Two series of livestock-production units have been developed--one based on concentrates consumed and the other on all feed consumed. Annual figures for the first series are computed by multiplying the total number of units of production 4/ by factors based on the <u>amount of concentrates consumed</u>. Annual figures for the second series are computed by multiplying the total number of units of production by factors based on the <u>amount of all feed consumed</u>, including roughages and pasture. The total number of units of production is the

<sup>4/</sup> Units of production: 100 pounds live weight of meat-producing livestock or poultry; 1,000 pounds of milk; 1,000 eggs; 1 goat clipped; for horses and mules, 1 head.

C

UPDATA

<sup>1/</sup> This report supersedes Livestock-Production Units 1910-1958 and Consumption of Feed by Livestock 1955-58, USDA Statis. Bul. 275, Dec. 1969, by Earl F. Hodges. Livestock data have been revised for 1955-61.

<sup>2/</sup> Feed consumption during the base period 1940-45 was used for all livestock except broilers, for which the period 1950-53 was used.

<sup>3/</sup> See Animal Units of Livestock Fed Annually, 1909 to 1961, USDA Statis. Bul. 324, February 1963, by Earl F. Hodges.

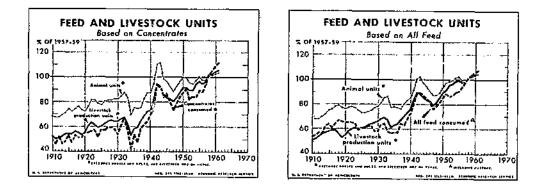

Figure 1

same for each series--the difference lies in the factors by which they are multiplied. Data upon which these series are based are available at the na-tional level only.

#### Calculation of Livestock-Production Units

The preliminary step in calculating the livestock-production unit series was the calculation of factors to be applied to the annual production figures. These factors are the ratios between the feed consumed by each type of livestock per unit of production during the base period and the feed consumed per year by one milk cow during the same period. 5/ The factors used for each kind of livestock and the feed-consumption data used in calculating the factors are given in table 1.

#### <u>Hogs</u>

An example of the method of calculation is the determination of the factor for hogs <u>based on concentrates</u>. During the period 1940-45, 487 pounds of concentrates were fed per hundredweight of hogs produced; 1,342 pounds of concentrates were fed annually to the average milk cow. Dividing 487 pounds by 1,342 pounds gives the factor 0.36. This multiplied by the total hundredweight of hogs produced in any year gives the number of livestock-production units from hogs for that year based on concentrates.

To develop the factors <u>based on all feed</u>, feed consumption is measured in feed units. <u>6</u>/ During the base period 1940-45, hogs consumed an average of 556 feed units of all feed per hundredweight of production compared with an annual average of 4,981 feed units per head for milk cows. Dividing the 556 pounds by 4,981 pounds gives the factor 0.11. This factor multiplied by the total hundredweight of hogs produced in any year gives the livestock-production units from hogs for that year based on all feed consumed.

<sup>5</sup>/ Data on feed fed per head and per unit of product during the base period is given in Consumption of Feed by Livestock, 1909-56: Relation Between Feed, Livestock, and Food at the National Level, USDA Prod. Res. Rpt. 21, Nov. 1958, by Ralph D. Jennings.

<sup>6/</sup> A feed unit is the equivalent in feeding value of 1 pound of corn.

<u>Milk</u>

The factor for milk production <u>based on concentrates</u> is determined as follows. During the period 1940-45, the average milk cow consumed 1,342 pounds of concentrates and produced 4,380 pounds of milk annually. Thus, an average of 306 pounds of concentrates were consumed per unit (1,000 pounds) of milk production. Dividing 306 by 1,342 gives the factor 0.23. Multiplying the units of milk production in a particular year by the factor 0.23 gives the number of livestock-production units from milk based on concentrates for that year.

To develop the factor for milk production <u>based on all feed</u>, the calculation is as follows. In the base period, an average dairy cow consumed 4,981 feed units per year, or 1,138 feed units per 1,000 pounds of milk. Dividing 1,138 by 4,981 gives the factor 0.23. Multiplying the units of milk production in any year by this factor gives the number of livestock-production units from milk based on all feed for that year.

#### Adjustment of Calendar-Year Production Data to Feeding Year

To facilitate comparison with the national supply and consumption of feed, for which data are based on the feeding year, 7/ livestock-production units also are based on the feeding year. The USDA calendar year estimates of annual production of milk and eggs; annual liveweight production of hogs, cattle, sheep, chickens, broilers, and turkeys; numbers of horses and mules on farms January 1; and number of goats clipped during the year are converted to a feedingyear basis as set forth below. Production data for the various kinds of livestock converted to a feeding-year basis are given for the years 1910-61 in table 2.

#### <u>Cattle</u>

In computing livestock production units, cattle production (excluding milk cows) is divided into two groups, "grain-fattened" and "other." The number put on feed during the year multiplied by the gain per head (assumed to increase gradually from 325 pounds per head in 1930 to 450 pounds in each year following 1958) equals the total gain of grain-fattened cattle. The difference between the gain of grain-fattened cattle and live-weight production of all cattle and calves is used for the production of "other" cattle. Calendar-year production data for these two groups of cattle are converted to the feeding year by adding 25 percent of the production in one calendar-year to 75 percent of the production in the succeeding calendar year.

#### Hogs

Data on live-weight production of hogs on a feed-year basis are calculated by first distributing production for the calendar years into quarters (as shown for 1962 in table 3), then totaling the production for the four quarters of the feeding year.

In estimating quarterly production, the number of hogs on farms January 1, the pig crop, and the death loss are used. The production from each group of hogs is distributed among the different quarters of the year, in accordance with the gain in weight during each quarter, by means of the percentages shown in table 4. The gain in weight made after January 1 by the spring pigs on hand

A DESCRIPTION OF A DESC

<sup>7/</sup> The 1960 feeding year, For example, was from October 1, 1960, to September 30, 1961, the period during which crop production from the 1960 growing season would normally be fed.

on that date is credited to the first quarter of the year, when these pigs are marketed. The gain in weight made after January 1 by the fall pigs on hand on that date is distributed among quarters thus: 55 percent to the first, 35 percent to the second, and 10 percent to the third, in accordance with the estimated gain of these pigs during each quarter. Sows and gilts on farms on January 1 (two-thirds of which are assumed to be gilts) are assumed to gain 125 pounds each during the ensuing year. Gilts held over another year (listed as sows December 31) gain another 25 pounds after the other gilts go to market. The gain in weight is credited to the respective quarters in accordance with the estimated gains during the quarter.

In the same way, estimates are made of the gain in each quarter by the spring and fall pigs farrowed during the calendar year. More than half the calendar-year pig crop is still "on farms, December 31." The rest have been marketed or are included in the death loss.

The percentages shown in table 4 have been used since 1952. From 1938 to 1952, production was concentrated more in the October to December quarter and a different set of percentages was used. Before 1938, concentration of production in the October to December quarter was even greater, and a still different set of percentages was used.

#### Milk and eggs

Monthly data for milk and egg production are published by USDA. Twelve months of production from October through the following September are used for the feeding-year production of milk and eggs.

#### Poultry

Production data for the calendar year following the beginning of the feeding year are used for meat-producing poultry, without adjustment, for the feeding year. The number of chickens raised in the calendar year, multiplied by the average weight of all chickens sold, is used for production of chickens raised. (Chickens raised are mainly for replacements in laying flocks.)

#### Sheep and lambs

The calendar-year production of sheep and lambs is converted to a feedingyear basis by adding 25 percent of the production in one year to 75 percent of the production in the succeeding year. For each 100 pounds of live-weight produced, about 19 pounds of wool are produced. No adjustment is made for feed required to produce the wool.

#### Horses and mules

Because no data are available with which to evaluate work done by horses and mules, the number of head on farms January 1 following the beginning of the feeding year is used for the production of this kind of livestock. Different factors are used to weight the number of colts and the numbers of horses and mules 2 years old and over. As USDA estimates of numbers of horses and mules were discontinued after 1960, the numbers are assumed to have been the same in 1961 as in 1960.

#### <u>Goats</u>

Number of goats clipped is the number raised for production of mohair during the calendar year following the beginning of the feeding year. In 1960, nearly 96 percent of the number reported were in Texas. Because goats are raised almost entirely on pasture, their production is included only in the livestock-production units based on <u>all feed including pasture</u>. The number of goats clipped is used rather than the amount of mohair produced.

#### Livestock-Production Units Based on Concentrates

Livestock-production units based on concentrates rose from 121.8 million in 1910 to 204.7 million in 1961, an increase of about 68 percent (table 5). The number of units excluding those from horses and mules more than doubled during that time.

Since 1950, hogs have accounted for approximately 37 percent of the livestock-production units based on concentrates, milk for 15 percent, eggs for 14 percent, cattle and calves for 17 percent, broilers for 6 percent, chickens for 4 percent, turkeys for 3 percent, and sheep and lambs for 1 percent. Foultry and eggs combined have accounted for about 27 percent of the total.

Several important changes have occurred in the composition of the livestock population during the more than 50 years represented in this series (table 6). The most obvious change reflected in the series is the decrease in the percentage of the units that comes from horses and mules--from 22.1 percent in the decade 1910-19 to 1.8 percent in the 1950's. Most of this decrease has been offset by the 14-percent increase in units from grain-fattened cattle and the 11.4-percent increase in units from broilers and turkeys. Broiler and turkey production developed on a large scale from the 1930's on. Grain-fattened cattle (cattle on feed) were first reported separately in 1929 (table 2). Since then, the units from grain-fattened cattle have increased nearly fivefold. About 10 percent of all concentrates fed to livestock in 1960 were fed to this class of cattle.  $\underline{8}/$ 

In proportion to other sources of livestock-production units based on concentrates, horses and mules and "other" cattle reached their peak before 1920, milk cows and sheep and lambs during the 1930's, hogs during the 1940's, and grain-fattened cattle and poultry in 1960 and 1961 (table 6).

#### Livestock-Production Units Based on All Feed 9/

Livestock-production units based on all feed, including pasture, increased from 88.7 million in 1910 to 135.2 million in 1961, a rise of about 52 percent (table 7). The number of units, excluding those from horses and mules, almost doubled during that time. In the period 1950-59, the approximate percentages of units from the different kinds of livestock were: cattle (other than milk cows), 42 percent; milk cows, 22 percent; hogs, 16 percent; eggs, 6 percent;

 $<sup>\</sup>underline{8}$ / Unpublished data, Farm Production Economics Division, ERS, USDA.  $\underline{9}$ / Measured in terms of feed units. See footnote 6.

sheep and goats, 5 percent; horses and mules, 3 percent; broilers, 3 percent; farm chickens, 2 percent; and turkeys, 1 percent. Nearly a fifth of the units from cattle came from grain-fattened cattle.

Between 1910-19 and 1960-62, units from horses and mules decreased from 26.3 percent of the total units in the all-feed series to 2.3 percent (table 8). During this period, units from cattle other than milk cows increased from 30.4 percent of the total to 42.4 percent. The importance of cattle production is further indicated by the fact that about 44 percent of all feed fed to livestock in 1960-61 was fed for cattle production.

#### <u>Comparison of Livestock-Production Unit Series</u> With Other Livestock and Feed Series

Percentagewise, the 1910 to 1961 increase in number of livestock-production units greatly exceeded the increase in number of animal units and was about the same as the increase in quantity of all feed consumed (table 9). This indicates a greater response in total livestock production than in animal numbers to increase in feed consumption. 10/ Livestock-production units increased 104 percent compared with a 51-percent increase in animal units and a 98-percent increase in all feed consumed by livestock. However, consumption of concentrates increased about 25 percent more than livestock-production units based on concentrates and 76 percent more than animal units based on concentrates. The percentage of concentrates in all feed fed to livestock increased 6 percent from the period 1909-19 to the period 1955-59. 11/

Before World War II, concentrates fed per livestock-production unit varied from a high of 0.87 ton in 1912 to a low of 0.58 ton in 1936, mainly according to variations in the supplies available. From 1940 to 1961, the amount fed averaged 0.70 ton, varying from 0.66 ton in 1947 to 0.76 ton in 1945 and 1961 (table 10). In general, the feeding rate per livestock-production unit was higher in the 10 years from 1910 to 1919 than in any of the following decades, even the 1950's.

Because feed is only one of several production inputs in livestock raising, efficiency of feed conversion into livestock products does not contribute to maximum profit in every operation. Therefore, efficiency of feed conversion has not been sought consistently by livestock producers over an extended period of time. <u>12</u>/ The quantity of all feed consumed per livestock-production unit has varied from a high of 3.10 tons in 1919 to a low of 2.19 tons in 1933 (table 11 and fig. 2). During both World War I and World War II and during the last 4 years, the rate of feeding was high. In the drought period of the 1930's, the rate was much lower.

10/ The animal-unit series are based on numbers of livestock rather than production. (See footnote 3.)

<u>11</u>/ For feed-consumption data before 1955, see USDA Prod. Res. Rpt. 21, table 64. Data for 1955-61 are available in unpublished form, Farm Production Economics Division, ERS, USDA.

(C)

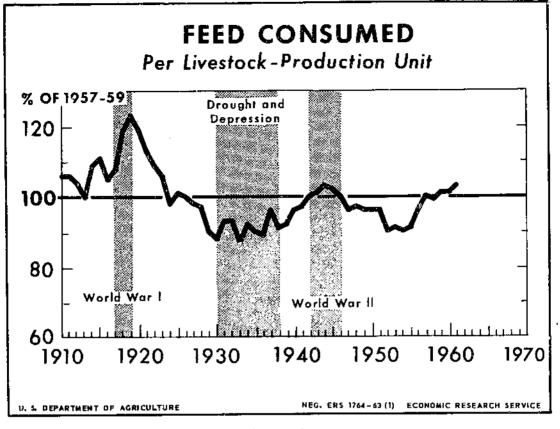

Figure 2

#### CHANGE OF BASE PERIOD

As indicated earlier, the base period used to calculate the factors for the livestock-production unit series is 1940-45 for all livestock except broilers. The base period for broilers is 1950-53. Because of the changes in feeding methods, practices, and efficiency which have occurred during the past 20 years, changing of the base period to a more recent time has been considered. Probably the same considerations are involved as in changing the base period for the animal unit series.  $\underline{13}/$ 

A comparison of estimated amounts of feed fed to various kinds of livestock per head or per unit of production during the base period 1940-45 and during the period 1955-59 is given in table 12. The most significant difference affecting the livestock production series is the great increase in feed per milk cow. All feed fed increased about 28 percent. Feeding of concentrates increased even more---a rise of nearly 50 percent. However, production per cow increased to such an extent that, per unit of milk production (1,000 pounds), concentrates increased only 13 percent and all feed actually declined nearly ' 4 percent.

<sup>13/</sup> Base period changes for the animal unit series are discussed in Animal Units of Livestock Fed Annually, 1909 to 1960, USDA Statis. Bul. 301, Dec. 1961, by Earl F. Hodges.

Both concentrates and all feed fed to "other" cattle (other than grainfattened cattle) have increased during the 20-year period. Measured in feed units, the total quantity fed has increased 4 percent. About 10 percent more concentrates are being fed. About one-fourth of the concentrates fed to this class of cattle are high-protein feeds such as oilmeals, which have relatively high feeding values compared with feed grains, roughages, and pasture.

Little change has occurred in the amount of feed fed per unit of production of hogs or chickens raised (for replacement purposes in laying flocks).

Significant reductions have occurred in feed fed to grain-fattened cattle, sheep and lambs, broilers, turkeys, and hens and pullets per unit of production.

In table 13, the factors for computing livestock-production units for each type of livestock production are given, using both the 1940-45 and 1955-59 base periods. The factors based on 1955-59 are lower for each type of production than those based on 1940-45. Not only is the total number of livestock-production units less if the base period 1955-59 is used than if the period 1940-45 is used, but the percentage of the livestock-production units coming from each kind of livestock also is changed. The differences appear to be large enough to warrant changing the base period to the later date as soon as practicable.

Although data are available to change this series to the later baseperiod, data are not now available to make a similar change in the animal-unit series. These indexes are more useful if kept on the same base period.

#### Table 1.--Factors for computing livestock-production units

Item	Unit of production	Concentrates fed per unit of production	based on	: All feed : : consumed : :per unit of : :production :	
		Pounds 1/		Feed <u>units</u> <u>1</u> /	
On farm Jan. 1:	•				
Milk cows 2/	: Head	1,342	1 4 5	4,981	
Horses and mules 2 years old and over		1,707	1.27	5,130	1.03
Colts	: do.	345	.26	3,449	.69
Goats clipped	do.			770	.15
Live weight produced:	e de l'Argent d'al.				
Grain-fattened cattle	: Cwt.	567	.42	914	.18
Other cattle	: do.	73	3/ .054	1,020	.20
Sheep and lambs	: do.	: 113	<b>.</b> 08	1,969	.39
Hogs	: do.	487	.36	556	.11
Chickens raised	: do.	: 519	.39	568	.11
Broilers	: do.	: 316	.23	362	.07
Turkeys	: do.	: 579	.43	677	.13
Milk	: :1,000 Lbs.	306	.23	1,138	.23
Eggs	: :1,000 eggs	: 599	.45	632	.13

1/ The average feed consumption in the years 1940-45 was taken as the base, except that 1950-53 was taken for broilers. These are the same periods used in Animal Units of Livestock Fed Annually, 1909 to 1961, USDA Statis. Bul. 324. 2/ The average annual milk production per cow on farms Jan. 1 for 1940-45 was 4,380 pounds. 3/ Prior to 1929, data for grain-fattened cattle were not published. Therefore, one factor, 0.098, based on concentrates, was used for all cattle and calves for that period.

Table 3.--Estimating the live-weight production of hogs by quarters, 1962

1/ Average weight of barrows and gilts at 8 markets, January through March.

Average weight of barrows and gilts at 8 markets, April through September.
 2/ Average weight of barrows and gilts at 8 markets, April through September.
 3/ 2/3 of sows and gilts were assumed to be gilts.
 4/ Average weight of barrows and gilts at 8 markets, October through December.

Table 4.--Estimated quarterly distribution of annual production of hogs

1/ Weighted by grain and other concentrates consumed. 2/ Weighted by total feed consumed. 3/ Weighted by the value of production. For calendar year beginning Jan. 1 after year indicated in stub. See Changes in Farm Production and Efficiency, U. S. Dept. Agr. Statis. Bul. 233, table 1. 4/ Excludes feed consumed by horses and mules and livestock not on farms.

Table 13.--Factors used to compute livestock-production units, 1940-45 and 1955-59 base periods

1/ Average annual milk production per cow on farms Jan. 1 for 1940-45 was 4,380 pounds; for 1955-59, 5,808 pounds.

2/ For broilers only, base period 1950-53 instead of 1940-45.
