MICROCOPY RESOLUTION TEST CHART NATIONAL BUREAU OF STANDARDS-1963-A MICROCOPY RESOLUTION TEST CHART NATIONAL BUREAU OF STANDARDS-1963-A

#### ABSTRACT

In 1970, the number of persons on farms in -ural areas of the United States averaged 9,712,000. In continuation of a longtime downward trend, the 1970 farm population was about 38 percent less than in 1960. This absolute loss of about 6 million during 1960-70 was the least for a decade since the 1930's. However, the relative loss was the highest recorded rate of decline for a decade.

During the decade, the Southern Region dropped from first to second place in number of farm residents. The North Central Region now ranks first. The ranking States in farm population are Iowa, Minnesota, and Illinois. States with the highest proportion of their people on farms are South Dakota and North Dakota.

Between 1960 and 1970, the net loss in the farm population through migration or reclassification of residence from farm to nonfarm averaged 694,000 annually. The annual rate of this loss was 5.6 percent.

Keywords: Farm population, migration.

#### SUMMARY

An average of 9,712,000 persons lived on farms in rural areas of the United States in the 12-month period centered on April 1970. Of the total U.S. population, only 4.8 percent, or 1 person in 21, lived on farms.

Between 1960 and 1970, in continuation of a longtime downward trend, the farm population declined by about 6 million, or 38 percent. Among the four regions of the country, the South continued to experience the most farm population loss. As a consequence, this region, traditionally the most populous in number of farm residents, now ranks second. The North Central Region had a modest loss and ranks first. Three North Central States, Iowa, Minnesota, and Illinois, lead in farm population. States with the highest percentage of their total population living on farms are South Dakota and North Dakota.

During the 1960-70 decade, a net average of 694,000 persons left farms annually. The annual rate of outmigration during this period was 5.6 percent. Although the number of net outmovers was fewer than in earlier decades, the rate of outmovement was about the same as in the 1950's.

#### FARM POPULATION ESTIMATES, 1910-70

1

by

Vera J. Banks and Calvin L. Beale  $\frac{1}{}$ Economic Development Division

#### INTRODUCTION

This report presents a continuous series of U.S. farm population estimates for 1910-70, and estimates of the farm population for geographic regions, divisions, and States for 1920-70. Annual estimates of the components of farm population change -- births, deaths, and net change through migration and reclassification of residence -- are presented for the United States, regions, and divisions for 1920-70.

All of the estimates for 1910-60 are as published in an earlier report in this data series and are included here for convenience (1). 2/ The 1961-70 estimates of the U.S. total farm population are also as published in earlier reports in this data series (1 and 8). However, the 1961-70 estimates for regions and divisions are revisions of earlier figures, reflecting changes in geographic distribution of the farm population as indicated by the 1970 Census of Population (2). The State farm population estimates for 1961-70 are new.

Although the data presented cover the period 1910-70, the analysis of farm population change relates primarily to the 1960-70 decade. An analysis of farm population changes for earlier years is available in (1).

Data on the characteristics of farm people by age, sex, race, and labor force status for 1960 through 1970 are presented in (4).

#### FARM POPULATION OF THE UNITED STATES

The number of persons living on farms in rural areas of the United States averaged 9,712,000 in the 12-month period centered on April 1970 (table 1). This represents a decline of about 6 million, or 38 percent, since 1960 (table 2). The sharp drop continued a longtime downward trend in the number of farm people.

<sup>1/</sup> The authors are grateful for the assistance of Peggy A. Colbert, Manuel L. Goldberg, Dorothy A. Hull, Anna E. Lane, and Gloria J. Jackson in the preparation of this report.

 $<sup>\</sup>frac{2}{2}$  Underscored numbers in parentheses refer to items listed in Literature Cited, page 13.

Except for brief interruptions during the depression and following World Wars I and II, the size of the farm population has steadily declined (fig. 1). This continuous decrease has been fostered in great part by lowered manpower requirements in agriculture, increased employment opportunities in nonagricultural industries, and the unfavorable disparity between farm and nonfarm incomes.

The decreasing number of farm residents has been accompanied by steady increases in the number of persons living in nonfarm areas. In 1910, the earliest date for which data are available in this series, the farm population was 32 million, and about 1 person out of every 3 was a farm resident. By 1950, the ratio had changed to 1 out of 7; by 1960; to 1 out of 12; and by 1970, when farm people were just 4.8 percent of the U.S. total, only about 1 person in 21 lived on a farm.

The relative loss in the farm population between 1960 and 1970 of nearly two-fifths is the highest recorded rate of decline for a decade. In the years prior to the 1940's, the farm population experienced minimal declines. However, with the advent of World War II, especially sharp and permanent drops occurred. In 1940, there were 30.5 million farm people, and they comprised more than a fifth of the national total. During the 1940's, the farm population declined by 7.5 million persons, a loss of 25 percent. Between 1950 and 1960, the absolute loss in the number of farm residents was at about the same level as in the 1940's -- but because of a smaller population base, the rate of loss increased to about 32 percent.

The acceleration in the rate of farm population loss to 38 percent during the 1960's resulted in a further sharp drop of 5.9 million persons. In 1970, the number of farm residents was less than 10 million for the first time in the 20th century. One would have to go back to the 1830's to find an earlier figure of this level. Although the farm population is at its lowest modern point, it is almost certain that some further decline will occur. There are still a number of middle-aged and older farmers living on farms of inadequate commercial scale from which reasonable incomes are difficult to obtain. As these men die or retire, their farms often will be consolidated into larger units.

#### GEOGRAPHIC DISTRIBUTION OF THE FARM POPULATION

The South has traditionally had the largest proportionate share of the U.S. total farm population. As late as 1950, more than half of all farm people lived on southern farms. However, persistently heavier rates of population loss have resulted in a continuous decline in the relative position of the South. In the past decade, 1960-70, the number of southern farm residents was reduced by nearly half, dropping from 7.2 to 3.8 million. The South's share of the national farm total fell from 46 to 39 percent (tables 3 and 4 and fig. 2). Consequently, in 1970, this region was no longer the most populous in farm population.

The more rapid decline of the southern farm population, compared with the rest of the Nation, has been associated with the mechanization of cotton production and near abandonment of the share-tenant system of farming. In addition, higher employment opportunities and living standards in nonfarm areas made obsolete the semisubsistence way of life and substandard housing and services that

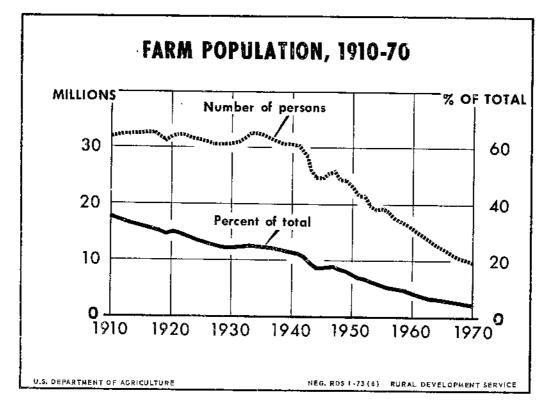

Figure 1

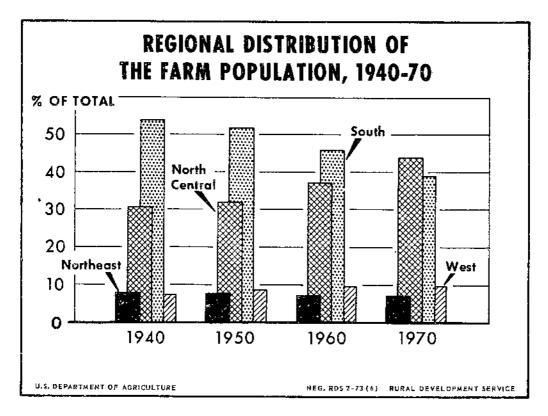

Figure 2

were characteristic of so much of the region. This heavier decrease also reflects the extremely high rates of outmigration of Negro farm residents, of whom more than 90 percent lived in the 16 Southern States at the beginning of the decade (3). Although data by race are not shown in this report, it is known from other sources that the Negro farm population decreased by about five-eighths in the 1960-70 decade (5).

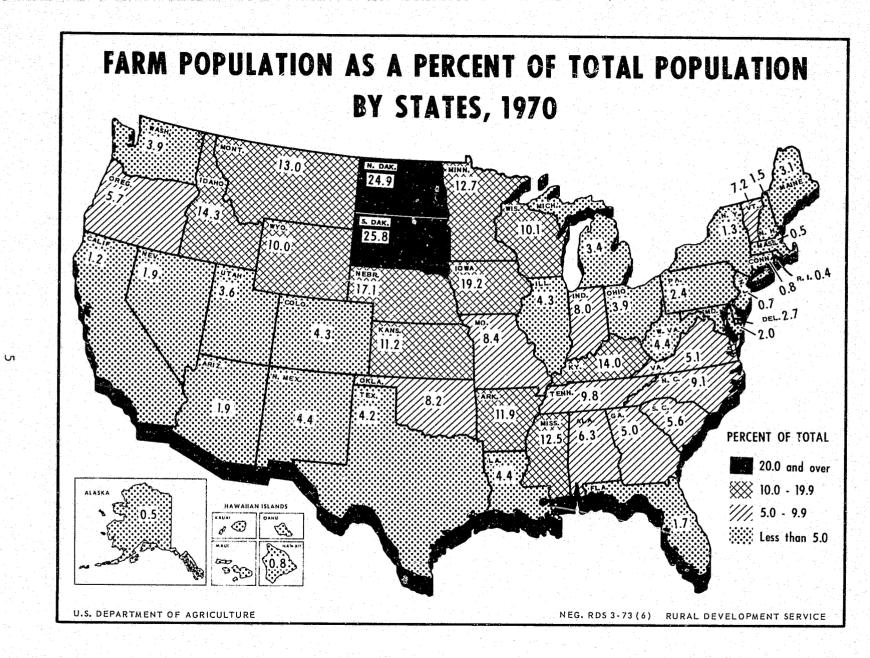

The decline in the South's share of the total farm population has been accompanied by an increase in the North Central Region's proportion. At midcentury, 32 percent of all farm residents were living in the North Central States; by 1960 their share had risen to 37 percent, and by 1970 to 44 percent. However, the North Central Region has experienced farm population decreases, as have all parts of the country. But farming in this region has not undergone such drastic changes as in the South, and population loss has been of a lesser degree. About the middle of the 1960-70 decade, the gradually rising proportion for the North Central Region became greater than that of the South. Consequently, for the first time, the North Central States now have the largest regional farm population.

Continuous population declines have had no major effect on the percentage of the total farm population residing in the Northeastern and Western Regions. Between 1960 and 1970, their proportionate shares of the total remained practically unchanged at 7 and 10 percent, respectively.

The more moderate rates of farm population loss throughout the North Central Region that led to the shift in rank between the North Central and Southern Regions also produced some marked changes in the relative ranking of States. For the first time, the States with the largest farm population are not southern. In 1970, Iowa ranked first in farm population. Previously, the leading States were North Carolina and Texas. However, these two Southern States experienced particularly high rates of farm population decrease in the last two decades, which caused Iowa, with only moderate declines during these periods, to advance from third rank in 1960 to first.

Two other North Central States -- Minnesota and Illinois -- were also involved in conspicuous changes in rank during the 1960-70 decade. Because of farm population losses considerably below the national average, Minnesota advanced from sixth in 1960 to second in 1970, and Illinois progressed from seventh to third. North Carolina and Texas, which had ranked first and second, respectively, in 1960, dropped to fifth and fourth in 1970.

In 1920, when State data first become available, 11 of the 48 States had a majority of their people living on farms, and in two-thirds of the States, farm residents constituted a fourth or more of the total. However, the continuing decline in farm population and steady increase in the number of persons residing in nonfarm areas has caused sharp drops in the farm share. By 1970, in only 13 States did the farm population comprise 10 percent or more of the State total population. States with the highest proportion of their people on farms were South Dakota and North Dakota, with 26 and 25 percent, respectively (table 5 and fig. 3).

Figure 3

#### COMPONENTS OF FARM POPULATION CHANGE

Estimates of the components of farm population change -- births, deaths, and net change through migration and reclassification of residence -- are available annually from 1920 through 1970 (table 6). However, because the estimates of change in farm population from one year to another fluctuate in part from sampling variation, averages for a period of years are deemed more reliable.

#### Natural Increase

Between 1960 and 1970, the excess of births over deaths in the farm population -- known as natural increase -- averaged 102,000 annually (table 7). This resulted from an average of 222,000 births and 120,000 deaths a year to farm residents. Natural increase among farm people las been declining steadily as high rates of outmigration have persisted among young farm adults of childbearing age, and as average farm family size has dropped. The farm population. which historically has been characterized as one of high fertility, averaged about 18 births per 1,000 total population during the 1960-70 decade, a significant drop from a rate of about 23 in the 1950's and 25 in the 1940's.

The number of deaths to farm residents also declined during 1960-70, but not enough to cause any significant change in the farm crude death rate. Consequently, with farm deaths at about the same level and with a considerable drop in farm births, natural increase for the 1960's was about 60 percent lower than in the 1950's when the excess of farm births over deaths averaged 271,000 annually (table 8). Even if there had been no changes in farm fertility and mortality levels, natural increase would have been lower because of the outmovement of potential young parents and aging of the population.

#### Migration

Natural increase is the ultimate source of population growth. However, in the farm population where the flow of migrants is responsive to many influences such as employment opportunities, mechanization, and technological advancements, migration becomes the dominant factor in population change, rather than the balance of births and deaths. Net change through migration in this data series includes not only those persons who made a physical move from farm to nonfarm areas, but also the loss that occurred when agricultural operations ceased on a place, and the occupants of the related dwelling units were reclassified from farm to nonfarm. Although exact figures are not available, actual migration is considered to be the larger of these two components. However, reclassification of residence is not of negligible amount, in view of abandonment of poorer farms, and the conversion of farmland to urban or other nonfarm uses. For convenience, the terms "migration" and "movement" will be used to refer to the total of both types of change -- physical migration and reclassification.

Except for the depression decade, 1930-40, the excess of farm births over farm deaths has been more than offset by net outmovement from the farm popula-Between 1960 and 1970, a net average of 694,000 persons left farms annution. This represented a cut in the volume of net loss through migration of ally.

nearly a third from the average of about 1 million for the 1950's and 1940's (fig. 4). With the decrease in size of the farm population, the possibility of the volume of farm to nonfarm migration reaching the magnitude of these earlier decades no longer exists.

Although the absolute average loss to the farm population from migration has declined substantially from previous levels, the percentage rate of net outmigration for 1960-70 was about the same as in the 1950's and even higher than in the 1940's. During the 1960's, a net average of 5.6 percent of all farm residents moved away each year, or ceased to farm -- although continuing to live on the place. For the decades of 1950-60 and 1940-50, the annual average rate of net outmigration was 5.3 and 4.4 percent, respectively. The implication is that the "push" and "pull" forces leading to migration have not lessened over the years, but rather that the supply of potential migrants has diminished. Heavy farm population loss from the South was reflected in the high rate of net outmigration from this region. During the 1960-70 decade, an average of 7.3 percent of the South's farm population left farms annually, the highest rate of net outflow among the four regions of the country (fig. 5). The smallest rate (3.8 percent) of net outmovement during this period occurred in the North Central Region.

#### DEFINITIONS AND EXPLANATIONS

<u>Population Coverage</u>.--The estimates presented in this report relate to the rural civilian population living on farms, regardless of occupation. For convenience, the term "farm population" is used without qualification, although the relatively few members of the Armed Forces living on farms are excluded.

<u>Farm Population</u>.--Since 1960, the farm population has been defined as all persons living in rural territory on places of 10 or more acres, if as much as \$50 worth of agricultural products were sold from the place in the reporting year. It also includes those living on places of under 10 acres, if as much as \$250 worth of agricultural products were sold from the place in the reporting year. Persons in institutions, summer camps, motels, and tourist camps, and those living in rented places where no land is used for farming are classified as nonfarm.

In the Current Population Survey of the Bureau of the Census (CPS), from which current estimates of the total population of the United States are obtained, unmarried persons attending college away from home are enumerated as residents of their parent's homes. In the Censuses of Population, such persons are enumerated as residents of the communities in which they live while attending college. The effect of this difference is to classify a larger number of collegeage persons as farm residents in the CPS than would be so classified under decennial census usage.

Previous to 1960, no specific criteria of acreage operated or value of products sold from a place were used to classify farm population. The change in definition in 1960 was largely stimulated by the fact that an increasing number of families whose livelihood was not gained directly from agriculture were living in the open country (many of them in former farm houses) (6).

( C UPDATA 1981

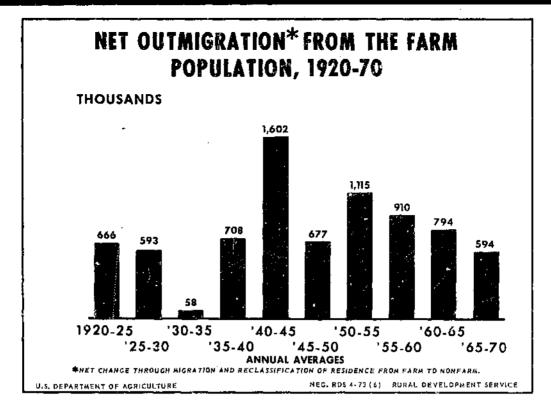

Figure 4

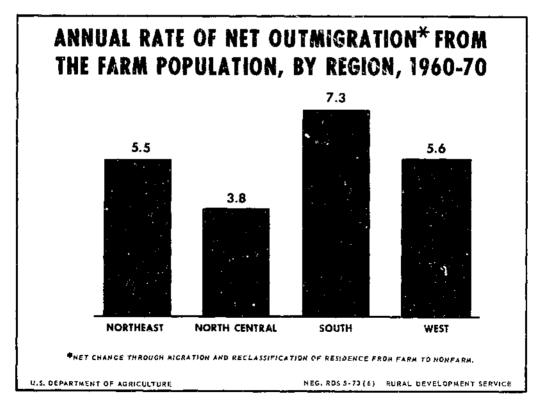

Figure 5

<u>April-Centered Annual Averages</u>.--April-centered annual averages of the U.S. total farm population for 1960 through 1970 were computed by using data from the five quarters centered on the April date for which the estimate was being prepared. For example, for April 1970, quarterly estimates for the months of October 1969 and January, April, July, and October 1970 were used with a weight of one-eighth given to each of the two October estimates and a weight of one-fourth to each of the estimates of the other 3 months. Estimates for years prior to 1960 relate to the month of April only.

<u>Rounding</u>.--The individual figures in this report are rounded to the nearest thousand and have not been adjusted to group totals, which are independently rounded. Percentages are rounded to the nearest tenth of a percent; therefore, the percentages in a distribution do not always add to exactly 100.0 percent.

#### SOURCE AND RELIABILITY OF ESTIMATES

The 1960-70 estimates in this report are based on data obtained from three principal sources. These are: (1) the Current Population Survey of the Bureau of the Census (CPS), which provides the annual estimate of the U.S. farm population; (2) the 1970 and 1960 Censuses of Population, from which benchmark datafor States, geographic divisions, and regions are derived; and (3) annual surveys of the farm population, conducted for the Economic Research Service by the Statistical Reporting Service, on which annual estimates of geographic distributions are based for intercensal years, and from which estimates of components of farm population change are derived annually.

<u>Current Population Survey.</u>--The U.S. farm population estimates for 1960-70 are April-centered annual averages based on data obtained in the CPS. That is, the estimates were computed by using data for the five quarters centered on the April date for which the estimate was prepared. (See "Definitions and Explanations" for further clarification.) These estimates were previously published in the cooperative annual Census-ERS reports (<u>4</u>). A detailed statement on the sample design, estimating procedures, and reliability of the estimates is presented in the joint Census-ERS release for the specified year.

Annual Farm Population Survey. -- The Economic Research Service and its predecessor agencies conducted an annual survey of the farm population and its components of change from 1923 to 1969. Utilizing USDA's crop reporting system, reports were collected through a mailed questionnaire (fig. 6). Respondents reported on the number of persons who were living on their own and neighboring farms at the beginning and end of a specified 12-month period. They also reported on births, deaths, and changes through migration which occurred during this period.

From these data, ratios of each component of change during the specified period to the sample farm population at the beginning of the period were computed for each State. By applying ratios from the sample to previously obtained expanded State estimates for the beginning of the period, estimates were obtained of each component of change during a year. These expanded estimates of births, deaths, and movement of persons to and from farms were summed to the populations at the beginning of the period to obtain a set of preliminary estimates of the

farm population at the end of the year. Final estimates were developed by adjusting the preliminary State estimates so that they would sum to the independent estimate for the United States provided by the CPS. Components of change likewise were adjusted to account for differences shown.

Although the basic procedures involved preparation of estimates for each State, postcensal estimates are published only for regions and divisions because of the limitations of the sample and the estimating procedures. When terminal as well as beginning benchmark Census of Population data become available for a period, the postcensal estimates are revised and become intercensal estimates. Data from the new Census of Population, along with data from the mailed questionnaires, previous censuses, CPS surveys, and other independent sources are utilized in making the intercensal estimates. Estimates for States as well as for geographic divisions and regions are issued retrospectively for intercensal periods.

<u>Reliability of the Estimates.</u>--Annual estimates of the U.S. total farm population are obtained from the CPS. As these estimates are based on a sample, they may differ somewhat from figures obtained if a complete census had been taken using the same schedules, instructions, and enumerators. As in any survey work, the results are subject to error of response and of reporting as well as to sampling variability.

The standard error is primarily a measure of sampling variability. It measures variations that occur by chance because a sample rather than the whole population is surveyed. The calculated standard error also partially measures the effect of response and enumeration errors but does not measure any systemmatic biases in the data. The chances are about 68 out of 100 that an estimate from the sample would differ from a complete census figure by less than the standard error. The chances are about 95 out of 100 that the difference would be less than twice the standard error.

When two estimates of the total farm population of the United States are compared, there is a reduction in the standard error of the difference when the estimates are for consecutive years. The standard error of such differences in the period 1967 through 1970 is about 150,000. The standard error of the difference between the 1966 and 1967 estimates of the U.S. farm population is about 200,000. The standard error for such differences for earlier years (back to 1960) is about 175,000. Tables of standard errors for April-centered annual averages for 1967 through 1970 are presented in (5).

Farm population estimates for geographic subdivisions and all estimates of components of change are based on U.S. Department of Agriculture mailedquestionnaire survey data, tied to benchmark figures from complete censuses, and adjusted to total estimates of farm population obtained from the CPS. The reliability of these estimates is therefore partly dependent upon the reliability of the U.S. estimate discussed above, and the mail survey data. The reliability of data from the mail survey alone cannot be assessed in terms of sample error. Reliability depends in part upon State-to-State variations in the size and representativeness of the mailing list, as well as upon variations in rate, representativeness, and accuracy of returns. The survey data on births and deaths consistently have appeared to be of poorer quality than those on population and

( C) UPDATA 1981

migration. They have been adjusted where necessary, with general State vital statistics trends used as guidelines for such adjustments.

In general, it should be noted that small figures, small changes, and trends over a short period of time may have less reliability than larger numbers and changes and trends over a period of several years.

#### METHODS OF DERIVING ESTIMATES

Benchmark Data for States, Geographic Regions, and Divisions.--The 1970 Census of Population rural farm population figure for States, which totaled 8,292,150, was inflated to the U.S. figure of 9,712,000 from the CPS (2 and 5). To do this, State inflation factors were developed which reflected the 1970 relationship between regional farm population estimates obtained from the Census of Population and the CPS. Consideration also was given to the individual State adjustments made in the inflation of the 1960 Census of Population farm population figure to the level of the CPS. Division and region benchmark estimates were obtained by summation of the appropriate State figures.

The rural population figures for States from the 1960 Census of Population (which yielded a U.S. figure of 13,444,898) were inflated to 15,635,000 from the CPS (1 and 3). The resulting 1960 estimates and the method of their development were published in an Garlier report of this series (1).

Division and Regional Population Estimates, 1961-69.--Methods of interpolation were utilized which considered the annual changes in the total farm population of the United States, along with the percentage that a division comprised of the U.S. total at the beginning and at the end of the 1960-70 decade. Thus, divisional percentages of the U.S. total for each year, 1961-69, were obtained. These percentages were then applied to the established total to obtain annual estimates of the farm population by division. Regional totals were obtained by summation of the appropriate division figures.

Division and Regional Components of Change Estimates, 1960-70.--Estimates of the components of change in the farm population developed annually for geographic divisions and regions were adjusted to reflect the changes in the revised annual farm population estimates. This was done by applying birth and death rates from the annual surveys to the revised division farm population estimates to produce revised estimates of the numbers of births and deaths. Annual revised estimates of net change through migration and reclassification of residence were obtained as residuals by subtracting the revised natural increase (births minus deaths) from the change in the population at the beginning and end of a specified year. Regional totals for the components were obtained by summation.

State Population Estimates, 1961~70.-~Annual State farm population estimates were developed by interpolating between 1960 and 1970 benchmark percentage distributions. The derived percentages were then applied to the established geographic division estimates.

JPDATA

Farm Population Estimates, 1910-60.--Farm population estimates for 1960 and earlier years were developed and published by the Economic Research Service and the predecessor agencies of ERS (1,7,9, and 10). These estimates are presented here for convenience without revision. A statement on the development of estimates for these years is not included in this report.

#### Table 1--Total and farm population of the United States, annual estimates, April 1910-70--Continued

<u>1</u>/ Includes the Armed Forces overseas except for 1910-16 and 1920-39. Data for those years relate only to persons residing in continental United States; numbers in the Armed Forces overseas during those years were fairly small. <u>2</u>/ Beginning 1960 includes Hawaii. <u>3</u>/ Beginning 1959 includes Alaska.

1/ Total population for April 1920 obtained by linear interpolation between the January and July 1920 figures of the Bureau of the Census.

 $\frac{2}{2}$  Population of District of Columbia is included in the South Atlantic Division, the South, and the United States total population figures. The rounded figures for the population living on farms in these areas are not changed by the inclusion of the District of Columbia.

1/ Beginning 1940, includes inductions and enlistments into Armed Forces, and persons returning from Armed Forces. For all years includes persons who did not move but who were in or out of the farm population because agricultural operations on the places where they were living either ceased or were begun.

2/ Less than 500 persons.
