INTRODUCTION

The returns received from banded birds during the period from July 1, 1923, to December 31, 1926, show a remarkable growth of interest and activity in this method of ornithological research. For the period under consideration 10,338 returns were reported to the Biological Survey. As compared with 1,746 returns during the initial period (January, 1920, to June 30, 1923), as given in Bulletin 1268 of the United States Department of Agriculture,³ these figures, covering a period of the same duration, demonstrate the remarkable increase in accomplishments of operators of bird-banding stations. These volunteer workers are entitled to full credit for the gratifying results obtained, which should serve as a stimulus for increased effort. During this, the second half of the seven-year period since this work was taken over by the Biological Survey, 234,692 birds have been banded, which brings the grand total up to nearly 270,000.

The returns here presented are the results of retaking banded birds either by operators at their trapping stations or by sportsmen and others who reported such as came to their attention. Increased experience in the proper operation of trapping stations has so well demonstrated the superiority of this method of investigation, particularly as regards the small nongame species, over the promiscuous

¹ The period covered by the present report begins with July 1, 1923, and ends with December 31, 1926, with a view to having subsequent reports begin and end with calendar years.

² The author desires to acknowledge the assistance given in the preparation of this report by his wife, Lulu M. Lincoln, and by Miss Myra A. Putnam and Mrs. Blanche W. Mahiman, of the Division of Biological Investigations. Their painstaking efforts to insure the accuracy of the data here presented are greatly appreciated.

³ LINCOLN, FREDERICK C. RETURNS FROM BANDED BIRDS, 1920 TO 1923. U. S. Dept. Agr. Bul. No. 1268, 55 p., illus., October 16, 1924.

banding of fledglings, that during the past few years the Biological Survey has declined to issue bird-banding permits to applicants who planned to band nestlings only. Unrestrained nest hunting has been found to cause a great loss to bird life, not because of possible desertion by parent birds, but because the human trails thus laid are sometimes followed (possibly only from curiosity) by several species of small predators, such as cats, weasels, and skunks. Where such trails lead to a series of bird nests, the result may be disastrous. There are, of course, certain avian problems that can be solved only through return data from birds banded as juveniles, but it has been found best to confine such work to the immediate grounds of trapping stations, where it is assumed that natural enemies are kept under control. The banding of the young of colonial birds, however, seems to have no deleterious effects.

Migratory waterfowl, particularly ducks, continue to furnish most of the returns, a fact readily explained from the millions of hunters in the field during the hunting season. Each hunter is a potential factor in return records for banded game birds, and occasionally also for banded birds of other classes. The possibilities of returns of nongame species are limited by the fact that, compared with the great numbers of hunters, less than 1,200 persons were holding nongame-bird banding permits at the end of the year, although there are frequently chance recoveries of such banded birds from other sources. Furthermore, not all cooperators are operating trapping stations, so that the number of workers effecting returns from these two classes of birds is markedly disproportionate. Station operators are therefore entitled to special commendation for the excellent results they have already obtained.

Students interested in this method of investigating the habits of birds will be aided by the appearance of these additional records, since with the rapid accumulation of the facts sought the time is not far distant when it will be possible to prepare reports concerning the migrations and other habits of certain species, based largely or wholly upon bird-banding data. Such reports will augment ornithological knowledge very considerably, and thus be of great service in dealing with those life-history phases that bring birds into intimate contact with human welfare. Because of the size of the North American Continent, the collection of return data from small bird stations will be slow. For this reason conclusive migration reports on most species, particularly the small nongame kinds, can be prepared only after years of intensive work at many stations, although the opportunity is open to every operator to make a contribution to knowledge of migration, based upon the results obtained at his station.

LIFE-HISTORY STUDIES

In addition to accumulating data for solving general migration problems, life-history studies of birds can be carried on at all banding stations. The possibilities in work of this nature are almost unlimited and not yet fully appreciated. The intimate contacts established between the operator and those individual birds that become frequent "repeaters," usually form the basis for life-history

investigations. Papers already published¹ by bird-banding co-operators show what can be expected, and other studies of a most important nature are in progress, some of which will probably appear in the early future. Investigations dealing with the individual characteristics of banded birds of the same species, as well as studies of feeding ranges, permanency of matings and consequent genetic matters, the dispersal of young birds and its bearing upon the distribution and extension of range of species, and many additional subjects that come constantly to the attention of investigators, will always prove interesting, and the published results will be distinct contributions to science.

AN INTERNATIONAL METHOD OF RESEARCH

The marking of birds by means of numbered aluminum bands is a method of scientific research international in scope. In a historical sketch of bird banding² prepared in 1921, the writer mentioned 18 different European bird-banding agencies, all of which dated from the pioneer work of the late H. C. C. Mortensen, of Viborg, Denmark. Previous experiments, such as the marking of young woodcock (*Scolopax rusticola*) on the estate of the Duke of Northumberland, at Alnwick, England, probably supplied the incentive for the scientific work of Professor Mortensen. Some European banding projects were never fully developed, and during the World War some were either abandoned or consolidated with others better able to continue them.

At the present time in the Old World the "marking scheme" sponsored by British Birds Magazine, under the direction of H. F. Witherby, is the most active. The work under this agency reached a climax in 1913, four years after it was begun, when nearly 15,000 birds were banded, but during the war the yearly totals dropped continuously, to 3,578 in 1919. Since that time, however, there has been a steady gain, and the report shows that 23,432 birds were banded in 1926, making a grand total of nearly 188,000. The results are being studied by A. Landsborough Thomson, together with data from the "Migration Inquiry" formerly conducted by the University of Aberdeen, Scotland, under his direction.

The Hungarian Central Bureau for Ornithology also has had its activities greatly reduced, although some banding operations are carried out each season. Two stations of the German Ornithological Society, at Helgoland and Rossitten, continue to operate, and important data have been obtained, particularly from birds bearing the bands of the "Vogelwarte Rossitten," which have been reported upon by Thienemann. In Denmark, since the death of Mortensen, in 1921, banding work has been carried on by Peter Skovgaard, and important reports have been published. A review of the principal

results obtained by the different European agencies was prepared by the writer and published in 1925.⁶

American students of bird banding will be particularly interested in a few birds banded in Europe and captured in the Western Hemisphere (fig. 1). Two of these were black-headed gulls (*Larus ridibundus*) from Rossitten, Germany; and two were kittiwakes (*Rissa tridactyla tridactyla*) from England. One of the black-headed gulls, banded July 18, 1911, was returned from Bridgetown, British West Indies, during November, 1911, and the other was recovered in February, 1912, near Vera Cruz, Mexico. The kittiwakes, bearing bands from British Birds Magazine, were banded at the Farne

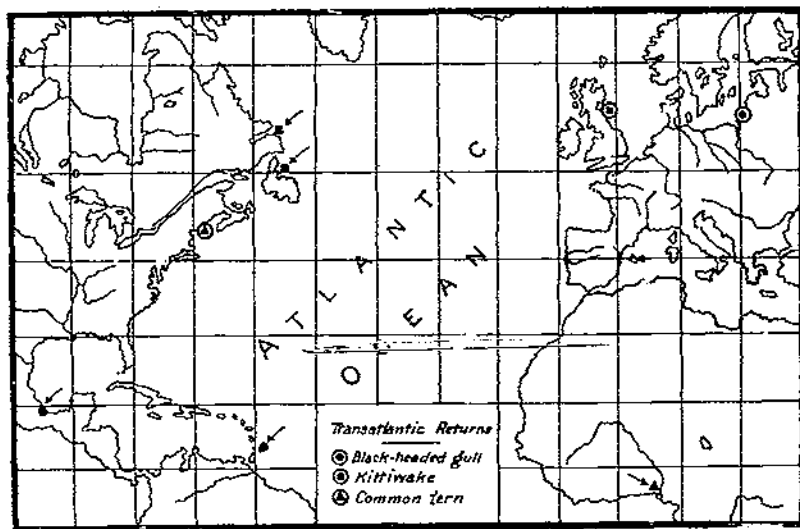

FIG. 1.—Transatlantic flights of banded birds. Two black-headed gulls banded at Rossitten, Germany, were recaptured; one at Bridgetown, Barbadoes, British West Indies, and the other near Vera Cruz, Mexico. Two kittiwakes banded at one of the Farne Islands, off Northumberland, England, were returned, one from Horse Island, District of St. Barbe, Newfoundland, and the other from Ticonaluk, Hamilton Inlet, Labrador; and a common tern, banded at Egg Rock, Me., was recovered from the delta of the Niger River, British West Africa. Corresponding symbols show the places of banding (in circles) and of return of the respective species

Islands, Northumberland, England, on June 28, 1923, and June 30, 1924. The first was killed at Horse Island, District of St. Barbe, Newfoundland, August 12, 1924, and the second was shot at Ticonaluk, Hamilton Inlet, Labrador, on October 28, 1925. Another kittiwake, bearing a band issued by the Zoological Museum, Copenhagen, Denmark, attached at Umanaq, Greenland, during the summer of 1926, was retaken about November 23, 1926, at Seal Cove, Newfoundland. An American common tern, banded at Eastern Egg Rock, off the coast of Maine, on July 3, 1913, was found dead in August, 1917, at the mouth of the Niger River, British West Africa.⁷ The records illustrate the importance of bird banding in future studies of bird migration, a greater degree of precision being attainable from this method than from any other. They also demon-

BANDED BARN OWLS

62467M

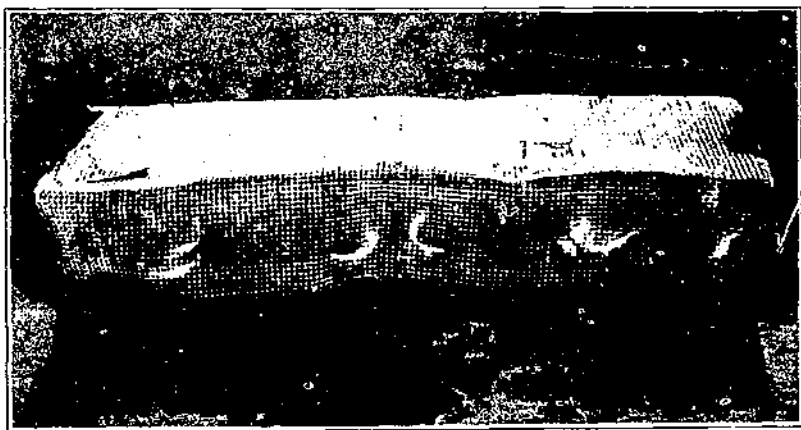

Nos. 235101 and 236102 banded July 1, 1923, near Knoxville, Tenn., by H. P. James, and photographed by him just before release. Six months later, on December 27, 1923, No. 236102 was killed near Opp, Ala., about 375 miles south of the place of banding.

A--SANDPIPER TRAP

B2616M

Successfully used near Milwaukee, Wis., by Herbert L. Stoddard and Clarence S. Jung in capturing for banding more than 40 sandpipers. It is a two-compartment trap with funnels at both ends and "leads" to direct the birds to the entrances.

B--NEAR VIEW OF SANDPIPER TRAP

B2577M

Contains several sanderlings and spotted and semipalmated sandpipers awaiting banding and release. Photographs from Milwaukee Public Museum.

A—CLAP NET WITH EXTENSION POLES

B2576M

Used in capturing robins, earthbirds, and cowbirds at night by Herbert L. Stoddard and Clarence S. Jung at a roost in Milwaukee, Wis. The net is held open on one side of the tree while an assistant startles the birds from the other. As the birds fly out into the net the two poles, held in the hands, are clapped together, thus holding the birds until they can be banded. Photograph from Milwaukee Public Museum

B—SURROUNDINGS OF SUCCESSFUL TRAPPING STATION IN CALIFORNIA

B2674M

Four single-compartment traps are shown, operated by Wright M. Pierce, at Claremont, Calif., where from February 13 to April 17, 1924, more than 300 birds were banded

strate the almost world-wide interest in bird-banding work, an interest peculiarly significant to American ornithologists and conservationists.

ECONOMIC ASPECTS

While bird-banding cooperators are concerned chiefly with the accumulation of basic facts pertaining to the life habits of birds, it is of interest to note the important bearing that these data have upon problems intimately associated with human economy. For this reason economic ornithologists as well as other groups of workers will carefully examine the returns obtained from banded birds.

The economic problem associated with the common crow is one that calls not only for the most exact knowledge of their food habits but also of the periodic movements of individuals. The control of these birds in certain localities is occasionally imperative, and as the control season is usually during the winter it becomes of first importance to know whether the individuals that make up the large winter roosts are the same as those that are guilty of depredations on crops during the spring and summer. Return records from banded crows will solve the problem.

The problem of controlling red-winged blackbirds, which late in summer and early in fall do much damage to the rice crops of the South and of California, furnishes an additional example of the possible practical use of bird-banding data. Under the feeding conditions at these seasons the birds do not readily take poisoned bait, and for this reason control measures must be taken at other times and places. The question, therefore, that confronts the economic ornithologist, which may be at least partially answered by banding red-winged blackbirds, is whether the individuals in the flocks that are so destructive in fall are the same as those that may be readily destroyed elsewhere at other seasons.

An important note by Magee,⁸ which is a direct by-product of a banding station, shows that the "budding" of fruit trees by purple finches at his trapping station had no bad effects on their bearing, but might have been responsible for an actual increase in the yield of fruit.

Grackles also present local problems of varying importance, as also do blue jays, robins, and many other species that are receiving the attention of operators of trapping stations. As banding data accumulate, it will become more feasible to take effective measures to control the depredations of those birds that are injurious to agriculture, horticulture, and allied industries when the individuals responsible are known to congregate elsewhere at other seasons of the year.

REGIONAL BIRD-BANDING ASSOCIATIONS

The field for bird-banding associations was practically filled by 1923, and no new ones have been formed during the period covered by this report. Those already in existence have devoted their energies to strengthening their organizations, working out programs of systematic operation, and developing additional trapping and banding stations (pls. 2 and 3). The greatest relative increase in the number of

⁸MAGEE, M. J. AN EXONERATION OF THE PURPLE FINCH. *Wilson Bulletin* 35: 167-169, September, 1923

new stations has been on the Pacific slope, where a lively interest has been manifest, resulting in steps for the solution of several local problems, under the leadership of J. Eugene Law and Harold Michener, of the Western Bird-Banding Association, originally organized as a banding chapter of the Cooper Ornithological Club.

As an outcome of the desire to prosecute investigations of life histories of birds through the banding method, many new types of traps have been designed to bring additional species within the scope of the study. Through correction of defects in traps heretofore in use it is possible now to recommend trapping equipment of greatest efficiency. Such work has been fostered by the central office in Washington and by the cooperative regional associations.

The importance of regional associations in furthering bird-banding activities has been demonstrated in the work of S. E. Perkins, 3d, of Indianapolis, Ind., one of the councilors of the Inland Bird-Banding Association. At the close of the fiscal year 1923 there were in Indiana 17 cooperators, not all of whom were maintaining bird-banding stations. Twenty-nine new cooperators had been added to the list by June 30, 1924, most of whom were taking an active part in the work by operating stations. This increase was due chiefly to the personal efforts of this association councilor, who not only located advantageous points for new stations and investigated the qualifications of the prospective cooperators, but also made demonstrations for the benefit of station operators.

With the development of these cooperating agencies, plans may be made for intensive work with certain species. As a means of determining the possibilities of such work, banding campaigns have been carried on by the Northeastern Bird-Banding Association, under the leadership of its secretary (now vice president), L. B. Fletcher, for the banding of black-crowned night herons and terns on the North Atlantic coast; and under the leadership of W. I. Lyon, president of the Inland Bird-Banding Association, for the banding of gulls and terns at colonies in the Great Lakes. Both of these programs have been successfully carried out, cooperators from other districts rendering assistance by visiting breeding colonies in their own regions. The results obtained have fully justified the efforts, and it is expected that the activities will be continued in future seasons.

RETURNS REPORTED TO THE BIOLOGICAL SURVEY

As in the previous report on bird-banding returns, the records here tabulated are presented without discussion. This is for the reason that the data will permit a wide range of interpretation, depending on many factors that would not apply equally to the different groups. Detailed discussion of all banding data from different species, including those published for the period 1920 to 1923, should form the subject matter of separate accounts.

Only those data are included in the tables that were received by the Biological Survey after June 30, 1923, and cover returns before January 1, 1927, except that when a banded bird has furnished two or more returns its complete record is grouped in one place for convenient reference, although this may repeat a few returns already published and result in a slight deviation from the alphabetical arrangement. The failure of some station operators to submit their

reports promptly has necessitated the inclusion of many returns bearing dates of recovery previous to July 1, 1923, for unfortunately they were not received in time to be incorporated in the earlier report.⁹ An examination of the returns will reveal a few cases indicating violations of the migratory-bird treaty act or of the regulations thereunder relating to the open seasons for migratory waterfowl. Some of these records represent birds accidentally caught in traps set for fur bearers, while others have been found to be actual violations. In all such cases appropriate action has been taken by the Biological Survey, or, in case of violations of the Canadian migratory birds convention act, by the Canadian National Parks Branch.

EXPLANATION OF TABLES

The method of presenting the tabulated data has been changed from that followed in Department Bulletin No. 1268, in the interests of economy, but no vital part of the record has been sacrificed.

The nomenclature is that of the Check List of North American Birds of the American Ornithologists' Union (third edition, 1910, with official supplements). As subspecific identity can usually be known in individual cases from the locality in which a bird is banded or recovered, identification in the tables is not carried below the species, although when subspecific identification is reported the information is preserved in the bird-banding files. When the typical subspecies does not occur in the United States or Canada, this fact is indicated by the abbreviation "subsp." following the scientific name.

The arrangement under each species is alphabetical throughout. The major grouping is by the State or Province in which the banding was done, and under each are the exact banding localities. The returns are listed alphabetically under the place of recovery, by State or Province, and then by exact locality, except that returns at the original station are given first, the word "Same" in the last column indicating this class.

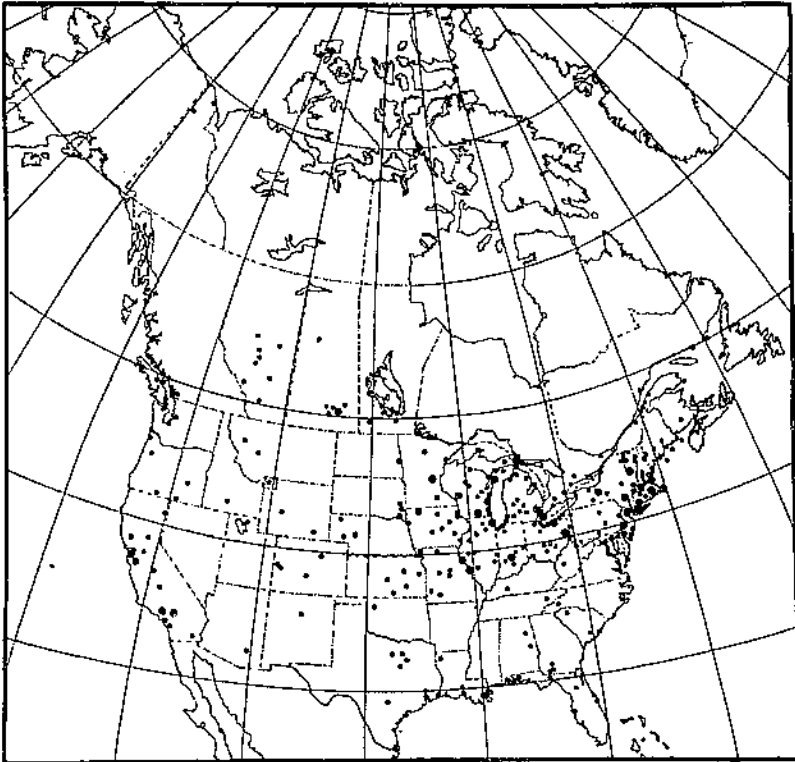

Return records are omitted when the banded bird is recaptured at another station that is only a short distance from the point of banding and the recovery date is within six months of banding, unless circumstances are such as to warrant its designation as a return. Such records, while frequently of decided interest, are not so much in the nature of "returns" as they are "repeats," for the evidence generally indicates that the carrier had been continuously in the immediate neighborhood. It is occasionally a problem to differentiate between "repeats" and "returns," and while the rule for a "return" (an interval of at least six months between banding and recovery), is admittedly arbitrary, the policy also has been to include as return records those that approach the dividing line, particularly if a migration has intervened. This results in seeming deviations from the "six months' rule" for a station return, but it does make available a class of data that may be of unusual importance.

The tables do not include records of banded birds accidentally killed or found dead at or near the trapping station shortly after banding, although these are termed "short-time returns." Such

⁹ Dept. Bul. No. 1268, 1921.

records are not numerous, and it is not believed that their inclusion in the tabulation would serve any useful purpose.

Band numbers preceded by an asterisk (*) are in the series of the American Bird Banding Association. The Biological Survey is still receiving returns from such bands, the original records of which are preserved in the bureau's files in Washington.

631244

FIG. 2.—Banding localities for the returns listed in this bulletin. Small spots represent single stations and larger spots groups of three or more stations in one general locality

Following the tabulation of returns is given an alphabetical list of banding localities and the cooperators, which is at times necessary to fix responsibility for identifications. This includes only those localities for which returns are listed in this report. A map showing these localities is included. (See fig. 2.)
