## SOMR TICHT ON BEEF PRORUGTION

Beef Production Returms 1923-24
The question of profitableness in beef cattile feeding is one that attracts the attention of many farmers everv fall. While besf catt pe can be made the means whereby large quantities of unsalable feeds can be marketed an element of speculation is involved, due to the nature of the business, which most farmers like to $\begin{array}{ll}\text { void. }\end{array}$

As bearing on this question the following data obtained from records on nineteen carloads of cattle fed out by farmers in Redwood and Renville counties last winter is presented. There were so many different methods of feeding that it is impossible to make a general statement as to what constituted the best feeding practices. Most of the cattle fed in this region come in the light weight class altho a few carloads of heavy aattle are fedeach yoar. No data from heavy cattle are inc luded in these tables.

Costs and Receipts for Winter of 1922-24
TABLF I

| Per Head | Average | Low | High |
| :---: | :---: | :---: | :---: |
| Initial cost | \$28.60 | \$12.48 | \$42.15 |
| Feed cost | 29.50 | 15.67 | 43.31 |
| Labor cost | 2.31 | 1.04 | 4.90 |
| Other costs | 4.86 | 2.88 | 7.51 |
| Total cost | 65.33 |  |  |
| Pork credit | 2.65 | 1.39 | 4.02 |
| Manure credit | 2.91 | 1.36 | 4.80 |
| Net cost | 59.77 |  |  |
| Sale value | 67.94 |  |  |
| Profit | 8.17 | -12.94 | 17.40 |

The c-ttle varied in weight from 298 to 685 pounds rer head at the boginning of the feeding period. This accounts for the wide range in the initial cost and in part for the wide range in feed cost per head altho the low고 feed cost ner head was not with the snallest animals. The variation in the item of labor was dua entirelv to feedire conveniences. The other costs are made up of interest on tle investment in cattle, shelter, marketing expense and other cash costs. This item will vary large lv as the investment per head varies.

In order to have broken even the farmer who lost most monev rer head wou 거 have had to receive $\$ 6.68$ per hundred weight while the ore who made tre most profit would have needed only $\$ 7.16$ per hundred weight. In the first case the cattle were sold for $\$ 5.64$ and in the other for $\$ 8.96$ per hundred weight. There was a loss of $\$ 1.04$ per hundred weight in the first instance and a gain of $\$ 1.80$ per hundred pounds in tre latter. This emphasizes the importance of meeting as nearly as possible the marlet demands in producing a product to sell if ore expects to get the highest prices.

Cost to Produce 100 Pounds of Gain
TABL II

Feed cost

| Averace | Low | High |
| :---: | :---: | ---: |
| $\$ 10.05$ | $\$ 6.96$ | $\$ 22.82$ |
| 2.44 | 1.82 | 6.38 |
| 10.52 | 8.54 | 23.39 |

Unit Requirements per 100 Pounds of Gain

| Grain - lbs. | 639 | 435 | 996 |
| :--- | ---: | ---: | ---: |
| Si lage " | 318 | 210 | 769 |
| Roughage " | 409 | 134 | 1110 |
| Pasture - days | 7 | 0 | 26 |
| Man la bor - hours | .27 | .14 | .80 |
| Horse labor " | .17 | 0 | 1.5 |
| Dai ly gain rer head - lbs. |  | 1.58 | .87 |

The lowest cost per hundred pounds of gain was with a load of Hereford calves of high grade. Their feed consisted of shelled corn, oats, silage and millet hay. The same feeds were fed thruout the period. They also made the highest daily gain jer head. These calves weighed 325 pounds at the start of the feeding period. The levest grain requirements per hundred pound s of gain was in a lot which received shellea corn, oats, silage and bundle corn while tre lowe st roughage requirement was in a lot which received sweet clover hay as the only roughage.

When one tuys feeder cattle at so much per pound he would like to know about what price he would hatre to receive when he sells them to avoid a loss. This can be illustrated by using the average data from these 19 carloads of cattle. The price of feeds used were corn 63 cents per kushel, oats 36 cents, si lage $\$ 4.50$ per ton, alfalfa $\$ 15.00$, clover $\$ 10.00$, wi ld hay $\$ 8.00$ and bundle corn $\$ 8.00$. The average initial weight per head was 549 pounds at a cost of 5.22 per hundred weight. Table I shows the average costs per head. and it will be noted that the net cost per head was 359.77 . The final weig ght per head of the cattle was 843 pounds which made it necessary for the cattie to sell for $\$ 7.09$ in order to break even. The necessary rargin would be $\$ 1.87$. Any price the cattle sola for over $\begin{gathered}\text {. } \\ 7.09 \\ \text { would be clear profit. On the average }\end{gathered}$ these cattle returred a profit of 97 cents per hundred pounds.

Trends in the Beef Industry
Tablo III shows some fluctuations in the beef industry in the United States and Minnesota. The number of cattle on farms include young deiry stock, some of which are used for consumptive purposes. In 1914 the number of cattie which were classed as strictly bsef animals was 76 fer cent of the cattle on farms, milk cows excluded. In 1923 the percentage had increased to 80 per cent. Of the total number of cattle beef cattle constituted 43 per cent in 1918 and 51 rer cent in 1923. The increase in exports was due to European demands. This tended to increase the price of beef which in turn stimulated production. Since 1920 there has been a decrease in both exports ard price, which was accompanied by a decrease in number of cattle.

Possibilities in Minnesota
Since beef cattle have apparently entered upon a more prosperous period many farmers are asking themselves this question. "Shall I expand my beef cattle enterprise." The answer to this question derends upon a good many things,

One must select a type of produvion which he wishes to follow and work with that end in view. Two types adaptaiole to Minnesota concitions are at his disposal. Many farms are especially well adapied to the fattening of feeder cattle. The area best suited to this form of production is locatod in the corn section of the state. It must necessarily be where corn does well and where it is cheap and will naturally bs limited to farms which inve a large part of their acrea age suited to crop production. To be successful in this type of beef production ore has to be a good judge of cattle and know when to buy and when to sell. This necessitates a marketing knowledge of livestock which not all men possess. In addition he must be well informed on feeding principles nd follow regularity in practices.

The other form of beef production is best suited to farms which have a part of the land avai lable for pasture and from which a considerable amount of cheap feed can be raised from the remaining land. On farms of this type it is possible to maintain a herd of twenty to thirty cows, raise the calves on the cows and feed them out as baby beef. The calves in this tyre of production would have to be of good quality since they are the only product from a year's keep of the cows, except the manure. It can be seen from this that the yearly cost of each cow can not be very high or one could buy feeder calves more cheaply. One establishing this type of farming would want to plan to stay by it for a period of years.

It cost a farmer in southern Minnesota 29.40 to raise a calf to three months of age in 1922, not aIIowing ary credit for the manure produced. No charge is made against the calves for the milk they got from the cows during this time. In 1923 it cost this seme fazmer 2 I .42 . The difference was due chiefiy to a larger percentage of cows calving and a larger percentago of calves being saved in 1923 than in 1922. This illustrates the value of having all cows produce a calf and under conditions which the calf will live.
