## INTRODUCTION

The bringing together of historical economic, agricultural, and industrial data is a necessary basic step in the study of interrelationships between agriculture and industry over long periods of broad economic development and over shorter periods of major economic cycles. A joint research project, under the Bankhead-Jones Act, of the United States Department of Agriculture and of the National Bureau of Economic Research, Inc., entitled "The Changing Balance Between Agriculture and Industry" has produced, as a byproduct, this report covering estimates of income from farm production in the United States, extending back to 1869 and including indices of farm production and prices.

For the general purposes of the broad study called for by the research project and particularly for use in comparison with similar series for nonagricultural income, production, and prices, it was necessary to prepare the estimates contained in this bulletin as a supplement to the estimates of farm income, production, and prices currently published by the Department of Agriculture. The nonagricultural series are now in the process of preparation, together with an analysis of both sets of data.

Readers will find that in certain respects the currently published estimates of gross income made by the Department of Agriculture since 1909 differ from those contained in this bulletin for the same period. These differences are dealt with in detail later, but it may be noted here that they arise chiefly from the fact that in its current estimates of income the Department deals with separate estimates by States. This necessitates a somewhat different concept of gross income than that required when dealing with agriculture as a whole in relation to nonagricultural industries. It should also be noted that revisions in the Department's current estimates are still in progress.<sup>1</sup>

This bulletin is published partly to help those who are studying the changing balance within the agricultural economy of the United States as it has developed since the Civil War, and as it has manifested itself in the changing proportion of total farm income from farm production received by the producers of the major farm products. The new agricultural data presented in this bulletin will be of particular use for research purposes.

When using these estimates of gross income from farm production, readers should bear in mind that some farmers have other sources of income, such as from labor performed off the farm, investments, gifts, and inheritances. The relative importance of these sources undoubtedly varies with the different branches and regions of agriculture, but comprehensive estimates of these items for the long period covered by this study are not possible. In all agricultural regions and all branches of agriculture, the production of farm products and the

<sup>1</sup> The revised data on cash income for calendar years since 1910 have been released. See Stine (78, p. 16).  
<sup>2</sup> Italic numbers in parentheses refer to Literature Cited, p. 152.

gross and net income derived therefrom are the main determinants of agricultural well-being.

Changes in relative shares of income received from the production of individual commodities are dealt with in a report entitled "The Composition of Gross Farm Income Since the Civil War," issued as a Bulletin of the National Bureau of Economic Research, Inc. (12).

Research students as well as other readers should recognize the necessary qualifications that are involved in a study of the sort here reported. Although a real effort was made to utilize the best available sources and material in constructing annual series, the annual data for some of the commodities, particularly for the period prior to 1900, are chiefly significant in showing long-time trends and may be less useful in analyses of short-time movements where a high degree of accuracy is required. These qualifications are dealt with in detail later.

The general nature of the material in this bulletin may be indicated at the outset by calling attention to the composite indices of agricultural production, prices, and income. These represent the final summary product of similar material for individual commodities.

The only heretofore available official index of agricultural production starting before the World War is an index of production of 12 important crops. In figure 1 this index is contrasted with a comparable one computed from the material contained in this bulletin and with an index of total production including livestock and livestock products, as well as crops. In this bulletin the long-time series on gross farm income, indices of production, and indices of prices will be designated as B. A. E.-N. B. E. R. (Bureau of Agricultural Economics-National Bureau of Economic Research).

In general, the two indices of crop production show the same long-time trend. Both reveal a diminishing rate of increase up to about 1915, and show no further rise after that. During the 1870's the annual rate of increase was about 6 percent, during the 1880's and 1890's about 2 percent, and during the first 20 years after 1900 about  $\frac{1}{2}$  percent. They differ markedly, however, in their year-to-year fluctuations, primarily because in the crop index as heretofore published constant weights are used and each crop is given an importance according to the value of its total production, whereas the index of the present study uses a cross of constant and annually changing weights and each crop is given an importance according to the value of its production used for sale or in the farm home.

The more inclusive measure of production, covering both crops and livestock, differs little from the indices of crops alone up to about 1920, but from then on it continues in line with the upward trend of the previous decade. This reflects chiefly the marked increase in the production of dairy and poultry products and truck crops, and production of livestock and livestock products per unit of feed crops.

The only index of prices received by producers starting before the World War heretofore available has been an index published by the Bureau of Agricultural Economics for the period 1910 to date. The present study makes available such a price index from 1869 to date, constructed in such a way as to be directly comparable with the B. A. E.-N. B. E. R. index of production. These two indices are shown in figure 2.

The course of average prices received by farmers has been dominated chiefly by monetary and business conditions and only partly by

changes in the aggregate volume of farm production. In a number of the individual commodities dealt with in this study, it will be found that the variations in production assume greater importance as a

FIGURE 1.—Comparison of indices of production, crop years, 1869-1937: Index of total farm production, index of 12 important crops, and index of 12 important crops (B. A. E.).

price factor than is the case when all farm products combined are dealt with. Even in this general illustration it is evident that the average of prices of farm products is affected by the course of farm production in general. Thus, during the downward course of prices

of the 1870's, 1880's, and 1890's there were three periods when production exceeded the long-time trend—the late 1870's, the late 1880's, and the late 1890's. In the first and third of these periods, the large volume of production intensified the decline in farm prices that was due to other causes, and in the other it prevented farm prices from responding fully to the prosperity conditions in the domestic markets.

The rise in farm prices from the 1890's to 1914 was somewhat more regular than was the decline during the period after the Civil War, but here too the effect, on price, of volume in excess of normal is apparent, particularly in the years 1904–06.

After 1914 several highly distinct price periods are evident: (1) The inflation and deflation associated with the World War, (2) the sus-

B. A. E. 35570

FIGURE 2.—Index of total farm production and farm prices, crop years, 1869–1937.

tained and relatively stable price situation of the 1920's, (3) the second major post-war price collapse between 1929 and 1932, (4) the rise between 1932 and 1937 associated with economic recovery, including devaluation of currency, Government expenditures, and two record droughts (1934 and 1936), and (5) the decline in 1937–38 associated with a decline in general business conditions and a return to conditions of surplus agricultural production and supplies.

The variations in gross income from farm production that resulted from these long-time and short-time changes in production and prices are shown in figure 3. During the 25-year period ending with 1896, it is clear that gross income rose only moderately, the rapid expansion in production being nearly offset by the accompanying decline in prices. The effect of variations in business conditions and in domestic demand is suggested in the cycles in income which reached their peaks in the prosperity periods of 1881–82 and 1891–92. From 1896 to 1914 the year-to-year variations in gross income are overshadowed

by the very marked long-time upward trend. If the rise and fall in farm income associated with the World War is set aside, the long-time upward trend that started after 1896 may be said to have terminated in 1929. The decade since then may be described for the present as one of a downward trend in gross farm income, with marked departures below that downward trend in 1932, and above that trend in 1937. In fact, the entire period after the World War may now be described as one during which agricultural prices and income followed a downward course as they did after the Civil War, with two periods of prices and income markedly below the course of the downward trend (typified by 1921 and 1932), and two periods of prices and income above the course of the downward trend (typified by 1925-29 and 1937).

In the body of this bulletin will be found in detail the sources, methods, and qualifications that are involved in the construction of

B. A. E. 35675

FIGURE 3.—Gross farm income, excluding omitted items, crop years, 1869-1937.

these general indices of production, farm prices, and gross income from production. The reader will find not only the volume, price, and income data relating to individual products and to the total of all products, but also similar data for groups of products for which such data have not heretofore been available. The individual products may of course be combined into various groupings to serve various purposes, but for more general use they have here been combined into the following groups (figures 7-10) and separate measures of production, prices, and income have been computed for each:

- (1) 12 important crops.
- (2) Staple food products (wheat, rye, potatoes, sweetpotatoes, dry beans, and rice).
- (3) Fruits (orchard and citrus, and grapes).
- (4) Dairy and poultry products.
- (5) Textile raw materials (cotton, flaxseed, and wool).
- (6) Meat animals.

The relative importance of these groups of farm products has changed a great deal over the last 70 years, judging from the following

brief comparison between the composition of total gross income for the calendar years 1869 and 1929 (table 1). For 1869 the estimated gross income from the commodities dealt with in this study amounted to about \$2,350,000,000 and for 1929 to more than \$10,700,000,000 involving an increase of 350 percent. Income from textile raw materials increased by about this same percentage, while income from staple food products and from livestock slaughtered increased only something more than 200 percent, and income from dairy and poultry products and from fruits increased, on the other hand, more than 800 and 1,000 percent respectively.

TABLE 1.—Changes in gross income from farm production between 1869 and 1929

Products	Gross income		Percent of total		Increase
	1869	1929	1869	1929	1869 to 1929
	Million dollars	Million dollars	Percent	Percent	Percent
Staple foodstuffs.....	380	1,223	16	11	222
Fruits.....	46	522	2	5	1,035
Dairy and poultry products.....	378	3,450	16	33	823
Textile raw materials.....	344	1,655	15	15	381
Livestock.....	923	2,830	40	26	267
Other.....	278	1,066	11	10	262
Total.....	2,349	10,726	100	100	350

Stated in another way, the relative importance of staple foodstuffs in the total of farm production has decreased over this 60-year period from 16 percent to 11 percent, but this has been chiefly made up for by the increased importance of fruits and truck crops. The relative importance of textile raw materials, chiefly cotton, has remained practically unchanged, and so has the total of livestock and livestock products. But there has been a decrease in the relative importance of production of livestock for slaughter from 40 percent to 26 percent, more than is compensated for by an increase in the contribution of dairy and poultry products from 16 percent to 33 percent.

These shifts in income clearly indicate where in agriculture and in consumer demand the dynamic changes have taken place. The detailed material in the following pages will be found useful in ascertaining in what commodities these relatively rapid and relatively slow changes have been, and are, taking place and the extent to which they are accounted for by changes in production and prices.

## SCOPE AND METHOD

### SCOPE OF THE INVESTIGATION

The student of problems in the agricultural economy is faced by a lack of long-term data on production, prices, and income. For several important farm products (such as livestock, dairy products, and fruits), only decennial census data on production have so far been available for earlier years. For many products, wholesale prices have had to be used as a substitute for farm prices. Yearly data on gross farm income have been published only since 1909; and even these crop-year data had to be revised and have recently been con-

verted to a calendar-year basis. No reliable measures of total farm production and of the general movement of farm-product prices received by producers were at the disposal of economists.

In this bulletin an attempt has been made (1) to assemble the best data on farm production, farm prices, and farm income for individual farm products; (2) to correct for inadequate data; and (3) to combine the estimates for individual products into measures of total farm production, an index of farm prices, and a measure of total gross income. These series are carried back, on an annual basis, to 1869. Gross income, price, and production were computed in order to obtain series essential for the study being made of trends and causes of changes in basic agricultural-industrial relationships. The attempt was rendered practicable by the availability of a great deal of revised statistical material in the United States Department of Agriculture that had not hitherto been utilized for this particular purpose, and was facilitated by the close cooperation between the Department of Agriculture and the National Bureau of Economic Research, Inc. As a result of this work annual data will be available as well as what might be called better bench-mark data for census years than those previously used.

#### TERMINOLOGY

"Farm value" of individual crops represents the value at farm prices of the total crop produced. In this bulletin, and in subsequent analyses, no direct use is or will be made of farm values. They were computed merely in order to obtain "gross income" whenever, as a step in estimating income, a constant ratio of gross income to farm value could be assumed. The basic concept for this study is gross income, which is synonymous with farm value after two major sources of duplication are eliminated—the value of feedstuffs produced but fed to livestock and the value of production used for seed. Essentially, therefore, gross income denotes the value (at farm prices) of the farm products sold by producers to the nonfarm economy and of the products (at the same farm prices) consumed in the producers' households.

Use of this concept results in a measure of gross income for the *farm economy* rather than a summation of the gross incomes of *individual farmers*. Such a differentiation does not involve notable discrepancies, except in those instances in which farm income results from sales of products to farmers who further process them before reselling to the nonfarm economy. An outstanding example is the interfarm sale of breeding and feeding livestock. A summation of individual farmers' incomes would give higher income estimates because the value of the breeder and feeder cattle would be included in the income of both the selling and the buying farmer. In this bulletin the concept "gross income for the farm economy" was applied whenever possible.<sup>3</sup>

In general, there is little difficulty in making a reasonable decision whether a particular item of income is a contribution to the total gross income of the farm or of the nonfarm economy. For instance, the value added in the processing of dairy products in manufacturing plants definitely does not belong to farm income; in line with institutional considerations, the processing is clearly one of the nonagricul-

<sup>3</sup> For reasons of expediency, the gross-income computations for corn deviate from the rule. Owing to lack of data, income arising from interstate sales between farmers had to be included, thus leading to an overvaluation, the magnitude of which cannot be adequately estimated. For a more detailed explanation, see the description of "income from corn production," p. 37.

tural entrepreneur's responsibilities; further, this part of income is recorded in the manufacturing census and thus is included in "non-agricultural income." The application of the preceding criteria avoids arbitrary decisions, so far as experience in this study is concerned.

This may be made clearer by an illustration. Citrus fruits are picked probably to a large extent, not by the growers themselves but by packer associations. The cost of picking therefore is not reflected in the gross income of many individual growers, but clearly enters into the gross income of the farm economy for two reasons: (1) From an institutional viewpoint picking is an agricultural responsibility; and (2) it is not elsewhere recorded in income statistics. Consequently, picking costs are included in the income estimates for citrus fruits.

The production data used in the indices of farm production and as weights in the indices of farm prices conform to the gross income concept. As shown in the description of the indexes and of the gross-income computation for individual farm products, "production" as used in the final computations refers to "production entering into gross income." That part of production which appears elsewhere as income from processed farm products (feed and seed) is excluded.

#### METHODS OF COMPUTATION

In cases in which data for intercensal years were not available, estimates were based on the best supporting data obtainable; often various methods of estimating could be checked against one another. As the reliability of the data varies from product to product and the methods of estimating had to be chosen according to the nature of the supporting data, both are described in detail for each product. As is usual in making estimates of this kind, the chosen methods are not always the only ones possible; other investigators might resort to other devices. But the authors believe that the selection of a different technique to estimate gross income from these few individual products would not result in substantial difference, and would not affect materially the income estimates either of groups of products or of all products.

The tables are divided into three separate parts showing since 1869 (1) Gross farm income, (2) indices of farm production, and (3) indices of farm prices. Gross income has been computed on both a crop-year and a calendar-year basis. Crop-year data are essential for many purposes, particularly for any exact analysis of crop-year prices and seasonal price movements in relation to supply-demand conditions. Calendar-year data are more useful in comparing agricultural with nonagricultural economic factors, particularly with nonagricultural income, which is available only on a calendar-year basis, except for recent years.

It has been the practice to combine income from livestock marketed during the calendar year with income derived from the crops produced in the crop year irrespective of the marketing period, and this combination has been termed crop-year gross income. To obtain a strictly calendar-year gross income, it is necessary to convert income from crops sold during a crop season, say August-July, to income received from one crop during the first part of a calendar year and

from the other crop during the last part of the calendar year. The conversion from the crop year to the calendar year is based on monthly marketings. As monthly marketings are available only for more recent years, this conversion for earlier years had to be made by applying an average rate of marketings derived from the more recent years.<sup>4</sup> This procedure is not likely to result in great errors. It is true that improved methods of growing, changes in the importance of early and late varieties, and improvements in transportation during this long period may have affected the seasonal distribution of marketings. But it is doubtful whether the proportion of a crop marketed between the beginning of harvest and the end of the calendar year has changed materially, even though marked changes may have taken place in the rate of marketings in any one month. It is believed that no serious errors result from the chosen procedure except possibly in years of severe price fluctuations, when the unavoidable assumption of constant seasonal marketings may introduce (for individual crops) noticeable discrepancies. The year-by-year data (for calendar years) for individual farm products should therefore not be used for analyses of short-term fluctuations that call for precise figures. For years before 1909 the authors doubt whether substantial improvements in the data would result from further effort. For the period since 1910 data that apparently will better indicate the yearly fluctuations in the marketings of individual products will eventually be released by the Department of Agriculture.<sup>5</sup>

However, since a larger percentage of total farm production and income is derived from products that are on a calendar-year basis (such as livestock and dairy products and some fruits), the calendar-year data for total farm production and for some of the subgroups, as well as for total gross income and for some income groups, are more reliable than those for some individual crops. In these instances their use for short-term analyses seems to be warranted.<sup>6</sup> In the description of the individual products, their reliability is discussed in more detail.

Table 2 summarizes the farm products covered, the periods for which the computation has been made for each, the quality of the data, and the methods of estimation. The second column refers briefly to the nature of the crop-year production data; the third column to the basis of the conversion from crop to calendar year; the fourth column gives the source of the price data for crop years; the fifth column the source or the manner of computation for calendar-year farm prices;<sup>7</sup> and the sixth column describes briefly the methods used in obtaining gross income from farm value.

<sup>4</sup> The conversion ratio was based on as long a period as possible. But when marketings since 1929 showed a marked shift in seasonality these years were omitted from the average.

<sup>5</sup> These estimates include the new B. A. E. (that is, Bureau of Agricultural Economics) calendar-year data of sales and home consumption, farm prices and gross income 1909-37 for wheat, rye, corn, oats, tobacco, cotton, cattle, calves, hogs, wool. Other calendar-year series are yet to be made available but these constitute a large part of the total. The estimates are described in more detail in the analysis of the individual products.

<sup>6</sup> Income from livestock, dairy products, chickens, and eggs—products whose production is on a calendar-year basis—constituted 55.8 percent of total income in 1869, 51.9 percent in 1900, and 58.7 percent in 1929.

<sup>7</sup> The Division of Statistical and Historical Research of the Bureau of Agricultural Economics collected farm prices of important farm products from various sources and combined them in the form of weighted averages. In this bulletin, in contrast to the current B. A. E. series, these price series are designated thus: (B. A. E.).

TABLE 2.—Synopsis of methods by which data on production, prices, and gross income were derived

Item	Production		Farm price		Gross income (basis for conversion from farm value)
	Crop year	Calendar year (basis for conversion from crop year)	Crop year	Calendar year	
Wheat.....	1869-1937, B. A. E.....	Marketings, B. A. E., 1924-35; actual B. A. E. data, 1910-37.	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.); 1910-37, B. A. E.	1869-1908, ratio of "sales and home consumption" to "total production," except in exceptional years; 1909-37, actual B. A. E. ratio, annually.
Corn.....	do.....	Marketings, Crop Reporting Board, 1920-29.	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.); 1910-37, B. A. E.	1869-1908, ratio, 1909-15, of "sales plus home consumption adjusted for exports" to "total production adjusted for exports;" 1909-37, actual B. A. E. ratio, annually.
Oats.....	do.....	do.....	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.); 1910-37, B. A. E.	1869-1909, ratio, 1909-14, of "sales plus home consumption" to "total production;" 1910-37, actual B. A. E. ratio, annually.
Barley.....	do.....	do.....	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.); 1910-37, B. A. E.	1869-1918, ratio, 1924-35, of "gross income" to "farm value;" 1919-37, actual B. A. E. ratio.
Rye.....	do.....	do.....	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.); 1910-37, B. A. E.	1869-1909, ratio, 1909-14, of "sales plus home consumption" to "total production;" 1910-37, actual B. A. E. ratio, annually.
Buckwheat.....	do.....	do.....	1869-1907, Dec. 1; 1908-37, season average.	Calendar-year income divided by calendar-year production.	1869-1909, ratio, 1909-14, of "sales plus home consumption" to "total production;" 1910-37, actual B. A. E. ratio, annually.
Flaxseed.....	1889-1937, B. A. E., 1869-1888, interpolated census.	do.....	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.); 1910-37, B. A. E.	1869-1937, ratio, 1919-37, of "gross income" to "farm value," since annual fluctuations are slight.
Hay.....	1869-1935, B. A. E., tame hay.....	Marketings, Crop Reporting Board, 1920-29, applied only when differences warrant computation.	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.), adjusted; 1910-37, B. A. E.	Computation of amount fed to cattle, horses, and mules in cities.
Potatoes.....	1869-1935, B. A. E.....	Marketings, Crop Reporting Board, 1920-29.	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.), adjusted; 1910-37, B. A. E.	1869-1923, B. A. E., ratio of "gross income" to "farm value," 1924-30; 1924-37, actual B. A. E. ratio.
Sweetpotatoes.....	do.....	do.....	1869-1907, Dec. 1; 1908-37, season average.	Calendar-year income divided by calendar-year production.	1869-1923, B. A. E. ratio of "gross income" to "farm value," 1924-30; 1924-37, actual B. A. E. ratio.
Cotton.....	do.....	1869-1909, average marketings, B. A. E., 1924-35; 1910-37, actual calendar-year sales, B. A. E.	1869-1907, Dec. 1; 1908-37, season average.	1869-1909 (B. A. E.); 1910-37, B. A. E.	Farm value=gross income.

733025-10-2

Cottonseed	Volume of cottonseed crushed.	do.	Value divided by production.	1874-1909, value divided by production 1910-37.	1867-1909, 67 percent of value of cottonseed crushed; 1910-37, B. A. E.
Tobacco	1869-1937, B. A. E.	1869-1908, average marketings, B. A. E., 1924-29; 1909-37, actual calendar year sales, B. A. E.	do.	Calendar year income divided by calendar year production.	Farm value=gross income.
Rice	1909-35, revised B. A. E.; 1869-1908, B. A. E., made consistent.	Marketings, B. A. E. 1926-33.	1909-37, B. A. E.; 1869-1938, estimated according to wholesale prices.		Average B. A. E. ratio 1924-33 applied 1909-37.
Dry beans	1914-35, B. A. E.; 1879-1913, interpolated census; 1869-78, extrapolated.	Marketings estimated by B. A. E.		1869-1923 (B. A. E.), adjusted; 1924-37, B. A. E. crop year price converted.	1910-37, actual B. A. E. ratio of "gross income" to "farm value"; 1869-1918, average B. A. E. ratio 1924-35.
Peanuts	1916-37, revised B. A. E.; 1890-1915, interpolated census; 1869-88, extrapolated census.	do.		1869-1915 (B. A. E.), adjusted; 1916-37, B. A. E. crop year price converted.	1869-1915, farm value-gross income; 1916-37, average B. A. E. ratio of "gross income" to "farm value," for the period 1924-35; 1924-37, actual ratio.
Cane sugar	1919-37, B. A. E.; 1869-1918, B. A. E., raw sugar from cane.	Crop sold in calendar year	1919-37, B. A. E. crop year price converted; 1869-1918, New York wholesale price adjusted.		Ratio of "gross income" to "farm value" estimated on basis of beet sugar.
Beet sugar	1911-37, B. A. E.; 1869-1910, B. A. E., raw sugar from beets.	do.	1911-37, B. A. E. crop year price converted; 1869-1910, New York wholesale price adjusted.		Estimated ratio of "gross income" to "farm value" based on contracts with growers and ratio of wholesale value to farm value.
Butter	B. A. E. estimates	Crop year=calendar year.	1869-1909 (B. A. E.); 1910-37, B. A. E.		Farm value=gross income.
Cheese	do	do	Computed weighted average price.		Do.
Condensed and evaporated milk.	do	do	Computed, based on butter price.		Do.
Fluid milk	Estimated as difference of B. A. E. "total milk" estimate and B. A. E. "manufactured dairy" estimates adjusted.	do	do.		Do.
Chickens	1925-37, B. A. E. estimates; 1879-1924, adjusted census data interpolated; 1869-78, extrapolated.	do	1910-37, B. A. E.; 1869-1909 (B. A. E.), adjusted.		Adjusted for mortality of chickens.
Eggs	1924-37, B. A. E.; 1869-1923, adjusted census interpolated; 1869-79, extrapolated.	do		1869-1909 (B. A. E.); 1910-37 B. A. E.	1924-37, B. A. E. data; farm value=gross income.
Apples (used only for checking purposes).	1889-1937, B. A. E.; 1869-88, cf. total orchard fruits.	Marketings 1917-23.	Computed weighted average price for marketing season.		Farm value=gross income, conversion from crop to calendar year based on marketings.
Total orchard fruits.	1924-37, actual B. A. E.; 1869-1923, adjusted census data interpolated by applying yield of apples and peaches.	do.	Estimated on the basis of apple prices.		Do.

TABLE 2.—Synopsis of methods by which data on production, prices, and gross income were derived—Continued

Item	Production		Farm price		Gross income (basis for conversion from farm value)
	Crop year	Calendar year (basis for conversion from crop year)	Crop year	Calendar year	
Grapes .....	1919-37, B. A. E.; 1899-1918, interpolated census (S. W. Shear); 1889-98, straight line interpolation of census data.	Crop year = calendar year	1924-37, B. A. E.; 1919-23, California price adjusted; 1917-18, f. o. b. price adjusted; 1887-1916, sweet wine price adjusted.		Farm value = gross income.
Citrus fruits .....	1919-37, B. A. E.; 1886-1918, based on shipments of California Fruit Growers Exchange and Florida Citrus Exchange.	Marketings 1924-28	Computed as gross income divided by production		Calendar-year income computed on basis of marketings 1924-28; 1895-1918, f. o. b. income converted to gross income on basis of cost data of California Exchange.
Slaughter:					
Hogs .....	1899-1937, B. A. E. estimates; 1869-98, estimates based on revised B. A. E. data of inventories on farms. Live weight per head, 1899-1937, B. A. E.; 1869-98, adjusted data of Cincinnati Price Current.	Crop year = calendar year	1869-1909, (B. A. E.) adjusted; 1910-37, B. A. E.		Farm value = gross income, exports of live hogs insignificant. Gross income = income from slaughter.
Cattle .....	1899-1937, B. A. E. estimates; 1869-98, estimates based on revised B. A. E. data of inventories adjusted for calves inventories. Live weight estimated from census and B. A. E. data. Slaughter supplemented by exports of live cattle.	.....do.....	.....do.....		Gross income = income from slaughter plus value of exports of live cattle (at farm prices).
Calves .....	1899-1937, B. A. E. estimates; 1869-89, estimates based on computed inventories of calves (using B. A. E. data). Live weight estimates based on B. A. E. and census data.	.....do.....	.....do.....		Gross income = income from slaughter. No exports.
Sheep and lambs .....	1899-1937, B. A. E. estimates of sheep and lamb slaughter combined; 1869-98, estimated on basis of per capita consumption (separately for consumption on farms and in cities.)	.....do.....	1869-89 (B. A. E.) adjusted farm price of sheep; 1890-1909, average of (B. A. E.) adjusted farm price for sheep and for lambs; 1910-37, average of B. A. E. farm price of sheep and lambs.		Do.

Changes in inventory values:				
Hogs.....	Based on B. A. E. estimates of revised census data. Live weight per head of inventories estimated on basis of census and B. A. E. data.	do.....	Same as live-weight price on which slaughter was based.	Gross income from slaughter corrected for changes in inventory values.
Cattle.....	Estimates of number of cattle 1 year old and over based on census and revised B. A. E. inventory data. Live weight estimated from census and B. A. E. data.	do.....	do.....	Do.
Calves.....	Cf. estimates of inventories used in slaughter series. Live weight estimated on basis of average January 1 census, B. A. E. data.	do.....	Cattle price used.....	Do.
Sheep and lambs.....	do.....	do.....	Sheep price used.....	Do.
Wool.....	1910-35, B. A. E.; 1869-1909, National Association of Wool Manufacturers.	Crop year=calendar year.....	1869-1909, (B. A. E.) adjusted; 1910-37, B. A. E.....	Farm value=gross income.

The estimates of gross income from individual farm products are described in detail to make clear the quality of the statistical data and to enable the reader to judge the reliability of the estimates. For several farm products no adequate data could be collected in the form of a consistent series. To make the totals of production, prices, and income comparable throughout the period covered, it was necessary to omit the partial data available for these products. Table 3 lists these products and gives gross income for the crop years 1924-35 according to computations made in the Bureau of Agricultural Economics.<sup>8</sup> Between 1924 and 1928 gross income from the omitted products constituted about 10.5 percent of total income (according to these preliminary B. A. E. data); in 1929 the percentage shrank to 9.5, owing mainly to the sharp reduction in income from forest products.<sup>9</sup>

TABLE 3.—Gross income derived from omitted farm products, crop years 1924-35

Item	1924	1925	1926	1927	1928	1929	1930	1931	1932	1933	1934	1935 <sup>1</sup>

<sup>1</sup> See the discussion on pp. 18-19.<sup>2</sup> The U. S. Department of Agriculture did not publish gross income data for crop years after 1935.

In the years of the deepest agricultural depression, 1931-33, the percentage rose to 12.4, 13.4, and 12.8, respectively, approaching again the 10.5 level in 1934 and 1935. Much of the fluctuation in the per-

<sup>3</sup> UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. FARM VALUE, GROSS INCOME, AND CASH INCOME FROM FARM PRODUCTION, 1924-28, 1929-32. GENERAL SUMMARY OF THE INCOME ESTIMATES. Release, April 1933, pp. 2-3. [Mimeographed.]

See also Crops and Markets (25, v. 10, pp. 144-149; and v. 11, pp. 314-355) and Agricultural Statistics (24, 1937, p. 332).

<sup>4</sup> However, the most recent revisions, not as yet published, show that actually gross income from forest products did not decline in 1929 and that income amounted to \$24.5 million instead of the unadjusted figure of \$17.2 million. This revision raises the 1929 percentage of income from the omitted items to 10.07.

centage after 1930 is due to the increasing importance of truck crops and farm vegetables. For the years since 1929, the authors' estimates of incomplete total gross income, therefore, cannot be considered a measurement of actual gross income. Particularly for comparisons with nonfarm income, both the absolute totals and the index of gross income should and will be corrected for the fluctuations in income from the omitted items (Figs. 5 and 6). The income derived from the omitted farm products makes up 12 percent of the incomplete total prior to 1929. For comparisons with absolute figures of nonagricultural income, the incomplete "total income" figure used here must, therefore, be raised 12 percent for the period prior to 1929.

Probably the percentage of total gross income not accounted for in the incomplete totals here used has not changed greatly during the period covered. The most important items not contained in the incomplete totals are truck crops, farm garden products, forest products, and nursery and greenhouse products. Truck crops, which amounted to 3.3 percent of total income in 1929, contributed only 1.2 percent a decade before, and were even less important earlier. On the other hand, income from forest products was 1.6 percent (2.3 percent according to revised figures not contained in table 3) of the total income given for 1929; for 1879, 4.5 percent. The importance of farm garden products has probably not changed much; income from nursery and greenhouse products ran about parallel with total income, which rose 492 percent between 1879 and 1929; income from nursery and greenhouse products rose 511 percent, according to census figures.

#### COMPARISON WITH OFFICIAL AND OTHER AVAILABLE DATA

As there is no way of arriving at sound yearly estimates for the omitted products and it is possible that in several years the income from these items either surpassed or fell somewhat below the 12-percent figure, which is here assumed to be constant, the unadjusted totals are used in comparisons with the various group subtotals. But after describing the nature of the estimates (tables 4, 5, and 6), tables 7 and 8 and figures 5 and 6 are included, showing the totals adjusted for a constant ratio of 12 percent for the omitted products for years prior to 1924. On the basis of the above evidence, the authors believe that these estimated totals, as well as the indices of gross income, both for the unadjusted total and for the various subgroups, provide a sufficiently accurate picture of the actual movement of gross income since 1869. (These indices are given in the section on gross income data, tables 11 and 12.)

For the period before 1909, only King's figures (9) on the total value produced in agriculture, based largely on census data, have hitherto been available. Despite the common realization that early census data were defective for a number of products, King's figures have been widely used as measures of farm income. It is not possible to trace in detail the reasons for discrepancies. They are sufficiently explained by deficiencies in early censuses and by differences in concept and in methods applied. It seems certain that income data based on early censuses cannot be used to indicate the trend of farm income, and if they are compared with data on nonfarm income serious inaccuracies will result.

<sup>1</sup> Adjusted incomplete totals (column 4) as percentages of complete totals (last row of table 3).

The total B. A. E.-N. B. E. R. income estimates for crop years are compared with the preliminary data of the Department of Agriculture in table 4. Gross-income estimates made by the B. A. E. for 1909-23<sup>10</sup> cannot be compared with the B. A. E.-N. B. E. R. totals, since the former are tentative, based on unrevised crop and livestock data, and represent only 40 crops instead of the 78 that are covered in the B. A. E. estimates for 1924-35. From these 40 crops about 90 percent of total income from crops was derived; the omitted products were assumed to be a constant percentage of the farm products for which actual data had been collected. Since the estimates here given take the latest revisions into consideration, it is certain that final estimates of the Department of Agriculture will be much closer to the 112-percent figure (B. A. E. estimate expressed as a percentage of the incomplete totals) than to the B. A. E. tentative estimates. A detailed check for this period is rendered impossible by the unavailability of crop year estimates by the Bureau of Agricultural Economics of income from individual farm products.

For 1924-33 (24, 1938, p. 432) the income estimates of the Bureau of Agricultural Economics are still in preliminary form, but eventual revisions are likely to cause only slight modifications. The greatest

<sup>10</sup> UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS, COMMITTEE ON FARM INCOME. TENTATIVE ESTIMATES OF GROSS INCOME FROM FARM PRODUCTION, CURRENT VALUE OF AGRICULTURAL CAPITAL AND SELECTED EXPENDITURES, 1909-1931. 23 pp. July 1932. [Mimeographed.]

differences between those estimates and the ones here given are for hay for the years 1924-28 and for dairy products since 1929, as table 5 indicates. The few instances in which the latter income estimates are based on a somewhat different concept than that of the Department of Agriculture are explained in detail in the text.

In figure 4 a comparison is made between the B. A. E.-N. B. E. R. series of gross income for calendar years and the new B. A. E. cash-income series for calendar years 1910-37. Since the movement of the final B. A. E. gross-income series may deviate from the B. A. E. cash-income series, no conclusions can be drawn from these comparisons. The differences between the two series in terms of B. A. E.

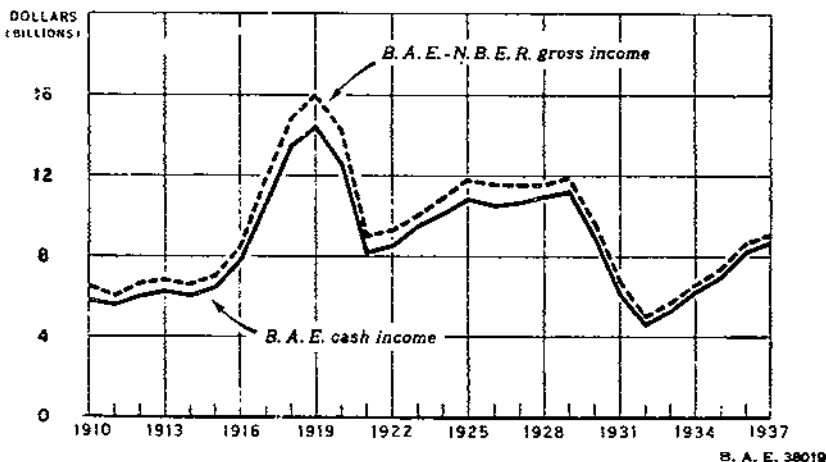

FIGURE 4.—Comparison of B. A. E.-N. B. E. R. gross income and B. A. E. cash income, 1910-37.

cash income as percentage of B. A. E.-N. B. E. R. gross income, calendar years 1910-37 are as follows:

1910.....	88.4	1917.....	89.6	1924.....	92.7	1931.....	92.4
1911.....	91.3	1918.....	90.5	1925.....	92.2	1932.....	92.4
1912.....	90.2	1919.....	90.3	1926.....	90.9	1933.....	92.8
1913.....	91.3	1920.....	87.9	1927.....	92.4	1934.....	95.6
1914.....	90.7	1921.....	90.0	1928.....	95.3	1935.....	94.1
1915.....	91.5	1922.....	91.7	1929.....	94.5	1936.....	94.6
1916.....	92.1	1923.....	93.2	1930.....	92.9	1937.....	95.8

Until 1921, this ratio fluctuated around 90 percent. In the 1920's and 1930's it was somewhat larger and in the years 1934-37 the ratio stood at about 95 percent.

To avoid breaks in the consistency of the B. A. E.-N. B. E. R. series, the income estimates, expressed both in millions of dollars and in index form, are not corrected for these differences. Estimates of the B. A. E. income from hay include interstate sales whereas the B. A. E.-N. B. E. R. estimate is based only on sales for the purpose of feeding animals in cities. To compute income from dairy products the authors use prices received by farmers for sales to wholesalers; the data of the Bureau of Agricultural Economics are from wholesale markets up to 1928; since 1929 prices of retailed milk and milk

products are used for the part of dairy products retailed directly by farmers. This change in computation results in a sudden rise of about 10 percent in 1929 and makes comparisons with earlier years impossible.<sup>11</sup> The Department of Agriculture will eventually revise these data to make a consistent series since 1909. Once these revised data become available they should replace the B. A. E.-N. B. E. R. data unless comparison with income data before 1909 is desired. The differences in livestock income arise partly because the livestock data used by the Bureau of Agricultural Economics in estimating total income are not the latest revisions. Table 5 shows that much of the difference disappears if we compare the estimates with the final revisions of the Bureau of Agricultural Economics (last column of the table); the slight discrepancies are the result of the incorrectness of changing proportions of sheep and lamb slaughter, and price differences that the B. A. E.-N. B. E. R. estimates do not take into account.<sup>12</sup>

TABLE 5.—Differences<sup>1</sup> between B. A. E. and B. A. E.-N. B. E. R. income estimates for crop years 1924-35

Year	Hay	Dairy products	Livestock	
			Unrevised B. A. E. <sup>2</sup>	Revised B. A. E. <sup>3</sup>
	Million dollars	Million dollars	Million dollars	Million dollars
1924	+155	+68	+82	+82
1925	+139	+61	+66	+66
1926	+135	+6	+68	+20
1927	+130	+21	+10	+25
1928	+141	+34	+25	+5
1929	+92	+309	-25	-10
1930	+77	+324	+29	0
1931	+55	+284	+25	+17
1932	+35	+249	-3	-5
1933	+45	+294	-44	-38
1934	+86	+411	+35	+35
1935	+55	+460	+29	+29

<sup>1</sup> Plus sign means that B. A. E. estimates are higher; minus sign, that they are lower.

<sup>2</sup> The data on total income so far released by the Department of Agriculture contain these "unrevised" livestock figures.

<sup>3</sup> UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. FARM PRODUCTION AND INCOME FROM MEAT ANIMALS, 1924-1935. 135 pp. September 1936. [Mimeographed.]

Table 3 indicates what percentages would have to be added to the B. A. E.-N. B. E. R. incomplete totals in order to obtain actual totals. To compare the incomplete totals adjusted for the omitted products with total income as used by the Bureau of Agricultural Economics, the differences in the methods of estimating the products mentioned above must be considered. In the last row of table 3, income from the omitted items is compared with the incomplete total estimates corrected for these differences in methods of estimation. Column 7 of table 4 contains the percentages that the incomplete totals adjusted for differences in methods of estimation are of actual total income (according to the B. A. E.-N. B. E. R. estimates). Column 6 contains the B. A. E. estimates of total gross income expressed as a percentage of the adjusted incomplete B. A. E.-N.

<sup>11</sup> SHEPARD, JOHN B., and SMITH, R. K. MILK PRODUCTION IN THE UNITED STATES. UTILIZATION ON FARMS AND VALUE, WITH DETAILS BY STATES, 1929 TO 1932. U. S. Bur. Agr. Econ. 52 pp. May 17, 1933. [Mimeographed.] See p. 4.

<sup>12</sup> Compare with the description of "Income from the slaughter of sheep and lambs", p. 121.

B. E. R. totals. Comparison of columns 6 and 7 demonstrates the closeness of the B. A. E.-N. B. E. R. estimates and the B. A. E. crop year income estimates. As minor revisions in the B. A. E. estimates are to be expected, it is safe to say that, except for the differences in methods of estimation for a few farm products, the B. A. E.-N. B. E. R. estimates of income for crop years are identical for all practical purposes with those of the Bureau of Agricultural Economics.

The calendar year gross income data in the B. A. E.-N. B. E. R. series cannot be compared with those of the Bureau of Agricultural Economics since the totals have not been released so far. The data for the major products have been used in the computation of the B. A. E.-N. B. E. R. series.<sup>13</sup> Owing to the use of averages in converting marketings from crop to calendar years, it is probable that the calendar-year income data for individual crops may show, in some years, discrepancies with the final estimates of the Bureau of Agricultural Economics. The group totals and the grand totals are likely to differ but slightly.

### PRODUCTION AND PRICE INDICES

Tables 58-75 contain the indices of farm production. The concept applied corresponds to that of gross income; that is, only that part of the production of each farm product which is sold or consumed in farmers' households is included. This part is termed "production entering into gross income." The tables containing the absolute figures of "production entering into gross income" precede the tables containing the indices. The index of "total farm production" contains the same products as the "total income" estimates. It represents, therefore, as do the various group indices, a measure of "net farm production."

The production indices are based on Fisher's Ideal Index formula (6):

$$\sqrt{\frac{\sum Q_1 P_0}{\sum Q_0 P_0} \times \frac{\sum Q_1 P_1}{\sum Q_0 P_1}}$$

$Q_0$  and  $P_0$  represent the annual average quantities and prices of the individual commodities in the base period (calendar years 1910-14 for calendar years, crop years 1909-13 for crop years).  $Q_1$  and  $P_1$  are quantities and prices in the given years. In the tables both data derived from the ideal-index formula and from its components, the weighted aggregates and the harmonic mean, are given. The weighted aggregates are called Arithmetic Index; for the harmonic mean the term Harmonic Index is used.

Tables 76-92 contain the indices of farm prices. As in the case of the production index, Fisher's Ideal Formula was applied:

$$\sqrt{\frac{\sum P_1 Q_0}{\sum P_0 Q_0} \times \frac{\sum P_1 Q_1}{\sum P_0 Q_1}}$$

and the Arithmetic Index, the Harmonic Index, and the geometric mean of these components, the Ideal Index, are presented in tabular

<sup>13</sup> Only preliminary total estimates for calendar years have been published: See press release of May 21, 1938. Farmers' Gross Income over 10 Billion in 1937. These data will be revised as final figures for individual farm products become available.

form.<sup>14</sup> The authors chose the "ideal" index formula for several reasons, both statistical and economic. It was essential for the purposes of this bulletin that the production and price indices meet the factor-reversal test—that the index of prices multiplied by the index of production equal the index of gross income. Only an index number that is based on a crossing of a fixed-year weight index and a given-year weight index conforms to this test. For purposes of subsequent analysis the authors were primarily interested in a measure of total farm production and of production in specific sections of the farm economy as far as they bear upon the income possibilities of the farm economy. Consequently, "net farm production" alone had to be considered and annually changing weights had to be introduced.

In measuring changes in farm prices the authors had to deal with the weighted average of prices of the farm products marketed and consumed in any particular year, which also suggests the choice of the ideal-index formula.

These indices, like all indices, must be used with some caution. The first reason concerns the nature of the basic material and not the particular index formula. Part of the production data are estimates that are sufficiently accurate to indicate the trend of production but cannot be regarded as an accurate measure of short-term year-to-year changes. This point must be kept in mind, particularly with respect to early data on slaughter and dairy production. The second reason concerns index numbers in general. The choice of the ideal formula does not raise distinct difficulties—the most common and most important use of a long-term index is in comparisons of widely separated periods. In a strict sense, such comparisons are not possible unless the composition of the indices and the influence of the fluctuations due to changing production (in the price index) and changing prices (in the production index) are considered. To make this possible, the authors present:

(1) the arithmetic index based on Laspeyre's formula  $\left(\frac{\sum P_1 Q_1}{\sum P_0 Q_0}\right)$  for production and  $\frac{\sum P_1 Q_0}{\sum P_0 Q_0}$  for prices, in which the weights are kept constant);

(2) the harmonic index based on Paasche's formula  $\left(\frac{\sum P_1 Q_1}{\sum P_1 Q_0}\right)$  for production and  $\frac{\sum P_1 Q_1}{\sum P_0 Q_1}$  for prices, in which the weights change yearly);

(3) the "ideal" formula, which is derived by crossing the constant-weight index with the "yearly changing weight" index.<sup>15</sup>

Since in the farm economy most commodities are produced throughout the entire period covered, though the importance of individual products changes, and since the commodities included in the B. A. E.-N. B. E. R., indices represent—measured in value—about 90 percent of the total throughout, a most important economic premise for the possibility of interyear comparison seems to be fulfilled, at least up

<sup>14</sup> After completion of the B. A. E.-N. B. E. R. indices and the explanations here given a monograph on index numbers in the field of agriculture appeared by Black and Mudgett (2). This Bulletin contains an illuminating discussion of the problems involved in the various methods of index-number computation. Though they indicate that theoretically a solution of the index-numbers problem is nearly possible, they recommend (2, p. 11) the use of the "ideal" index formula, or a close approximation, and the presentation of separate indices based on base-year weights and on current-year weights, and stress the need for computing indices for longer periods.

<sup>15</sup> The tables containing the various production and price indices present one decimal. In the computations, two decimals were carried to make the automatic check of the ideal-index formula possible, where the product of the price and production index equals the index of gross income. It should be understood that in view of the quality of some estimates, the decimals are not always meaningful.

to about 1913, when truck crops became increasingly important. The omission of truck crops does not, however, greatly impair the representativeness of the production indices since then. It is true, the B. A. E.-N. B. E. R. production index, not including truck crops, rose from 109.60 in 1919 to 125.74 in 1937, or 14.7 percent; the Department of Agriculture index of truck-crop production (24, 1937, p. 380)<sup>16</sup> increased from 58 to 129, or 122 percent. But as truck crops represented only 1.4 percent of income in 1919 and 4.4 percent in 1937, their inclusion in this production index would hardly change the percentage increase, 1919-37, for the all-inclusive index. A comparison for 1919-34 shows that the B. A. E.-N. B. E. R. production index fell 5.8 percent, truck-crop production rose 89.7 percent. The inclusion of truck crops would have reduced the decline in the B. A. E.-N. B. E. R. total production index to 5.1 percent. To arrive at a fully representative index of production for the post-war period, the authors adjusted their index (excluding truck crops) for the movement of truck-crop production as revealed in the Department of Agriculture index. This was done by computing a weighted average of the changes of the B. A. E.-N. B. E. R. index and the truck-crop index and applying it to the former, excluding truck crops (table 6). The more inclusive index should be substituted for their long-term index for all purposes for which completeness of coverage is required. But, except in a few years the differences are insignificant and even in 1934, the year of the largest discrepancy, it is less than 1 percent.

TABLE 6.—B. A. E.-N. B. E. R. index of total farm production compared with index of total farm production including truck crops, crop years, 1919-37

[1909-13=100]

Year	Truck crops omitted	Truck crops included	Year	Truck crops omitted	Truck crops included
1919	109.8		1929	120.8	121.4
1920	114.7	115.0	1930	120.1	120.1
1921	102.2	102.1	1931	126.1	125.6
1922	110.2	110.9	1932	119.1	119.7
1923	112.9	112.7	1933	114.1	113.9
1924	118.8	119.1	1934	103.3	104.0
1925	118.7	118.9	1935	108.2	108.3
1926	124.2	123.9	1936	109.8	109.9
1927	119.2	119.8	1937	125.7	125.3
1928	124.3	124.0			

Comparison of the Arithmetic Indices and the Harmonic Indices shows that in general the differences are small. Whenever the differences are notable, they are due to changes in production (in the price indices) and to changes in prices (in the production indices) and comparisons for periods far apart can then not be made if strict accuracy is needed.

The B. A. E.-N. B. E. R. production indices cannot be compared with indices previously available since all except the B. A. E. index of 12 important crops are based on unrevised crop data. The B. A. E. index (13, 18) applies constant weights derived from the base period 1910-14 to total production of 12 major crops. The B. A. E.-N. B. E. R. index covers the same 12 crops but excludes production

<sup>16</sup> The weights used in this index are those for the base period 1924-29. In combining our index with the truck crop production index, we applied yearly changing weights based on value data.

used as seed and fed to livestock. The two indices are similar in their long-run movements but differ greatly in their year-to-year movements, owing to the use of "total production" in the B. A. E. index and to the different methods of computation. Figure 1 gives also the B. A. E.-N. B. E. R. index of total production for crop years. Though it indicates that the trend between 1880 and 1910 was similar to that of the B. A. E.-N. B. E. R. 12-crop index, it indicates also that before 1880 and after 1910, the 12-crop index is not representative of total farm production. The production indices for the various subgroups cannot be classified here. The differences in their long-term and year-to-year movements are large enough to warrant separate analysis which will be undertaken in the study on trends and causes of change in basic agricultural-industrial relationships.

The basic statistical data and methods by which farm price, production, and gross income were derived are described, beginning on page 33. This part is preceded by the summary tables 7-12 and figures 5-10.

<sup>1</sup> Contained in the index of crop production of the Bureau of Agricultural Economics: Wheat, corn, oats, barley, rye, buckwheat, flaxseed, hay, potatoes, sweetpotatoes, cotton and cottonseed, tobacco.  
<sup>2</sup> Wheat, rye, potatoes, sweetpotatoes, dry beans, rice.  
<sup>3</sup> Orchard fruits, citrus fruits, grapes.  
<sup>4</sup> Cotton, cottonseed, flaxseed, wool.  
<sup>5</sup> Slaughter of cattle, calves, hogs, sheep and lambs, and export of live cattle.

<sup>1</sup> Contained in the index of crop production of the Bureau of Agricultural Economics: Wheat, corn, oats, barley, rye, buckwheat, flaxseed, hay, potatoes, sweetpotatoes, cotton, tobacco.

<sup>2</sup> Wheat, rye, potatoes, sweetpotatoes, dry beans, rice.

<sup>3</sup> Orchard fruits, citrus fruits, grapes.

<sup>4</sup> Cotton, cottonseed, flaxseed, wool.

<sup>5</sup> Slaughter of cattle, calves, hogs, sheep and lambs, and export of live cattle.

B. A. E. 35540

FIGURE 9.—Gross farm income, calendar years 1869–1937: Total, 12 important crops, staple foodstuffs.

B. A. E. 35541

FIGURE 10.—Gross farm income, calendar years 1869-1937: Meat animals and export of live cattle, dairy products, chickens, and eggs, textile raw materials, fruits.

TABLE 11.—Indices of gross income, from various groups of farm products and from total farm production, crop years [1909-13=100]

Year	12 im- por- tant crops <sup>1</sup>	Staple food- stuffs <sup>2</sup>	Fruits <sup>3</sup>	Dairy prod- ucts, chick- ens, and eggs	Textile raw mat- erials <sup>4</sup>	Meat animals slaughter and ex- port of live cattle <sup>5</sup>	Meat ani- mals ad- justed for changes in inventory values	Total farm pro- duc- tion	Total farm production, adjusted for changes in inven- tory val- ues of meat animals

<sup>1</sup> Contained in the index of crop production of the Bureau of Agricultural Economics: Wheat, corn, oats, barley, rye, buckwheat, flaxseed, hay, potatoes, sweetpotatoes, cotton and cottonseed, tobacco.

<sup>2</sup> Wheat, rye, potatoes, sweetpotatoes, dry beans, rice.

<sup>3</sup> Orchard fruits, citrus fruits, grapes.

<sup>4</sup> Cotton and cottonseed, flaxseed, wool.

<sup>5</sup> Slaughter of cattle, calves, hogs, sheep and lambs, and export of live cattle.

## SOURCES OF DATA AND METHODS OF ESTIMATING PRODUCTION, PRICE, AND INCOME

Sources of data and methods of estimating production, price, and income are here considered for 12 important crops that are included in the Bureau of Agricultural Economics crop production index (19, p. 2).

### WHEAT

Figures of total production of wheat for crop years are the latest revisions as published by the Department of Agriculture. Weighted season-average farm prices, available only since 1910, are used in computing farm value and gross income, 1910-37. Before 1910, December 1 farm prices were applied.<sup>17</sup> Reliable estimates of the wheat used for seed and feed have been made available recently by the Bureau of Agricultural Economics for 1909-36.<sup>18</sup> The seed use for these individual years was estimated by elaborate methods and these estimates may reasonably be regarded as the best available. Before their release the authors made estimates on the basis of previously published data<sup>19</sup> for the years since 1919. The results of this method approximated the recent Bureau of Agricultural Economics estimates which were used in the computation for 1909-37. During the years 1909-14, an average of 10.1 percent of the total wheat crop was used for seed purposes.

The authors' original estimate of feed use took account of earlier estimates by the then Division of Crop and Livestock Estimates which showed that 3.84 percent of the total wheat crop was fed to livestock on farms in 1919. This estimate was corroborated by an independent estimate of the Food Research Institute (16, p. 365). According to this source, the per capita feed use was 0.29 bushels during 1909-14. Converted to absolute figures, the feed use would have been 27.5 million bushels out of a total production of 717 million bushels (average 1909-14). Thus, the feed use would have amounted to 3.83 percent of total production. The recently published Bureau of Agricultural Economics estimates indicate a slightly higher ratio, 4.1 percent. It can be regarded as merely an approximation. The feed-disposition figures for years before 1925 were obtained on the basis of relative prices of wheat and corn as indicated by the relation between relative price to quantity fed during 1925-36. The authors used these annual disposition figures for 1909-37 and assumed a combined seed and feed use of 14.5 percent of total wheat production for 1869-1908 except for years when exceptional conditions prevailed.

In a publication the Department of Agriculture states (20, p. 1): "Wheat is not usually regarded as a substitute for corn as a feed for livestock, but a small carry-over of old corn and a new crop greatly reduced by drought leaves many farmers short of corn for feed \* \* \*." The exceptional years when the ratio of wheat prices to corn prices was low, but presumably favored relatively larger wheat feedings are 1869, 1874, 1881, 1887, 1890, 1892, 1893, 1894, 1901. For

<sup>17</sup> This device is commonly resorted to in Department of Agriculture analyses as well as in those of other investigators. Henry Schultz (14, p. 173) found that the coefficient of correlation between December 1 and season-average farm prices during 1909-29 was 0.9745.

<sup>18</sup> UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. DISPOSITION OF WHEAT, RYE, BUCCWHEAT AND FLAXSEED, CROP YEARS 1909-36 BY STATES. 78 pp. September 1938. [Processed.]

<sup>19</sup> DIVISION OF CROP AND LIVESTOCK ESTIMATES. FARM VALUE, GROSS INCOME, AND CASH INCOME FROM FARM PRODUCTION, 1919-32. Release. March 1934. [Mimeographed.]

these years the combined feed and seed ratio was raised to 17 percent of total production, that is, a feed use of 6.5 percent instead of about 4 percent which is that in "normal" years, was assumed. This percentage was obtained by observing the increase in feed use from 1909-17. During this period 1911, 1913, and 1916 were "exceptional" years and the feed use increased 2.1, 1.6, and 3.1 percent respectively. Increasing the feed ratio 2.5 percent in "exceptional years" prior to 1909 can be regarded merely as an approximation, but it seems certain that this adjustment for the years noted comes nearer the actual feed use. The accompanying percentages, derived from crop-disposition figures of the Bureau of Agricultural Economics<sup>20</sup> were used in deducting the amount of wheat retained for seed and feed to obtain net production since 1909.

1909	12.6	1916	17.8	1923	18.7	1930	26.5

1913	14.4	1920	12.5	1927	14.7	1934	28.5
1914	11.7	1921	14.4	1928	14.9	1935	25.3
1915	10.5	1922	15.5	1929	16.9	1936	25.6

Gross income was computed as the product of production entering into gross income and farm price. Production entering into gross income, farm price, and gross income for crop years 1869-1937 are shown in table 13 and figure 11.

To estimate income data for calendar years, sales and human consumption on the farm during the calendar year were evaluated at calendar-year farm prices. As monthly marketings are available only for recent years an average derived from data for these recent years was applied for the entire period. During the crop years 1924-33 (22, *Yearbook 1935*, p. 359) marketings from July to December amounted to 79.8 percent, and from January to June to 20.2 percent, of total marketings. These percentages are used for 1869-1923. Thus, "production entering into gross income"<sup>21</sup> during the calendar year 1900 is composed as follows: Marketings from January to June 1900 were 20 percent of the wheat crop 1899-1900; marketings from July to December 1900 were 80 percent of the crop 1900-01. The conversion from crop- to calendar-year marketings was carried through on this basis from 1869 to 1909. In connection with the study of income parity for agriculture (estimates for some individual crops and livestock items have already been issued) the Department of Agriculture is attempting to estimate sales, home consumption, and gross income for calendar years for all products. The authors used calendar-year data on sales, home consumption, farm prices, and gross income from that study for 1910-37.

The (B. A. E.) calendar-year farm prices of wheat were used for 1869-1909. This price series includes average weighted farm prices of the following States: Since 1869, Wisconsin, New York, Maryland, Virginia, Illinois; since 1879, Minnesota; since 1890, South Dakota; since 1895, Nebraska. Beginning with 1910, weighted calendar-year farm prices as currently published by the Bureau of Agricultural

<sup>20</sup> See footnote 18.

<sup>21</sup> In the computation, "crop-year production entering into gross income" was converted into calendar-year marketings in order to take into account also those years for which the percentage used for feed and seed is higher than the constant ratio applied for most of the years. This expression is used to indicate the quantity of the total crop that constitutes sales and use for home consumption. In the tables "calendar-year production" refers to the part of the crop of 2 crop years that was marketed during the calendar year.

Economics were applied. To make this price series consistent with the B. A. E. data, statisticians in the Bureau computed an adjustment factor based on the 1910-14 average of both series. The (B. A. E.) wheat price thus found appeared to be only 0.1 percent lower than

B. A. E. 35604

FIGURE 11.—Wheat: Production entering into gross income, farm price, gross income, crop years 1869-1937,

the current B. A. E. price. In view of this small difference the authors used the (B. A. E.) wheat-price series unadjusted. Total production multiplied by calendar-year farm price gives the farm value of wheat. As in the computation based on crop-year data, farm value corrected for the value of wheat used as seed and feed is gross income (table 13).

## CORN

Crop-year production data are the latest revisions of the United States Department of Agriculture. For 1869-1909, December 1 farm prices were used; since 1910, weighted season-average B. A. E. farm prices of the Department of Agriculture<sup>22</sup> were used. Data on the utilization of the corn crop for purposes other than feed and seed (that is, commercial sales for nonagricultural purposes) are too scanty to warrant their use to determine production entering into gross income. Therefore it was not possible to adhere to the authors' usually rigid concept of gross income. Department of Agriculture estimates of the disposition of the corn crop<sup>23</sup> are based on sales data for census years, and for other than census years, on the relationship between the percentages sold (as derived from the census) and reports from crop correspondents on the percentage of the crop shipped out of the county where grown, and on the percentage of the crop sold or for sale. To this is added home consumption (for human purposes). Obviously, this method does not make possible deduction of interfarmer sales between States, and their importance cannot be determined. But undoubtedly a considerable quantity of corn shipped between counties and States and used for feeding farm livestock (which is ultimately represented in income from livestock) cannot be deducted. As there was a wide variation in exports during the period, the authors deducted annual exports from the annual quantity sold and used for home consumption and computed the ratio of the difference to "total production adjusted for exports." The average ratio 1909-15, 18.5 percent, was applied from 1869 to 1908; "production entering into gross income" was computed by adding to the quantity resulting from this ratio the annual quantity exported. Since 1909 the quantity of corn sold and used for home consumption as estimated by the Department of Agriculture was used (table 14).

TABLE 14.—Corn: Ratio of production entering into gross income to total production, crop years, 1909-38

<sup>22</sup> Schultz (*l. c.* p. 175) obtained a coefficient of correlation of 0.9790 between the season average farm price and the December 1 price for 1909-29.

<sup>23</sup> UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. DISPOSITION OF FEED GRAINS (CORN, OATS, BARLEY, AND GRAIN SOYBEANS), CROP YEARS 1909-1938. June 1938. [Mimeographed.]

Production entering into gross income, farm price, and gross income for crop years are shown in table 15 and figure 12.

To compute calendar-year production, crop-year production entering into gross income was converted to calendar year production on the basis of marketings for the period 1920-29.<sup>24</sup>

B. A. E. 35552

FIGURE 12.—Corn: Production entering into gross income, farm price, gross income, crop years 1869-1937

Average marketings amounted to 29.7 percent between October and December and to 70.3 percent between January and September. For 1869-1909, the (B. A. E.) calendar-year farm price was applied.

<sup>24</sup> Unpublished data obtained from the Crop Reporting Board, U. S. Department of Agriculture.

Farm prices of the following States are included in the corn price: Since 1869, Wisconsin, Illinois, New York, Maryland, Virginia, Maine; since 1891, South Dakota; since 1895, Nebraska. This price seems to be weighted in favor of the surplus-producing States. As the 1910-14 average is 9.4 percent less than the B. A. E. farm price, prices from 1869 to 1909 were adjusted accordingly. Farm values were obtained by multiplying calendar-year production by the (B. A. E.) farm prices from 1869 to 1909; since 1910 by multiplying B. A. E. revised calendar-year prices by calendar-year production. The conversion from farm value to gross income 1869-1909 is based on the same method as for crop years. Production entering into gross income, farm prices, and gross income 1910-37 are data of the Bureau of Agricultural Economics (table 15).

**OATS, BARLEY, RYE, BUCKWHEAT, POTATOES, SWEETPOTATOES, AND  
FLAXSEED**

As the procedure of estimating income is essentially the same for oats, barley, rye, buckwheat, potatoes, sweetpotatoes, and flaxseed, it would be repetitious to describe it in detail for each. Therefore the production, price, and income computations for these products are explained in footnotes to each table. Table 16 shows the ratio of production entering into gross income to total production which is identical with the ratio of gross income to farm value. Production entering into gross income, farm price, and gross income derived from these products for crop years are shown in tables 17-23 and figures 13-19.

<sup>1</sup> Explanation.—Total production: Crop year: B. A. E. data. Calendar year: Converted from crop years on the basis of average marketings (Crop Reporting Board files) 1920-29. Average marketings January-June=32.7 percent of preceding crop. In the computation 66.7 and 33.3 percent were used. Production entering into gross income: 1909-35, annual data of ratio gross income ÷ farm values were applied. (Cf. table 16); 1869-1908, average ratio 1909-14 (30 percent) was used. Sales and home-consumption data of Bureau of Agricultural Economics for calendar years 1910-37 were applied. Farm price: Crop year: 1869-1907, B. A. E., Dec. 1 farm price; 1908-37, B. A. E., season average farm price. Calendar year: 1869-1909, (B. A. E.) farm price was raised 6.3 percent. The following States are included: Since 1869, Wisconsin, Illinois, New York, Maine, Maryland, Virginia; since 1890, Minnesota; since 1891, South Dakota; since 1895, Nebraska. 1910-37, B. A. E. revised calendar-year farm prices. Gross income: Crop year: Crop-year production entering into gross income × Dec. 1 farm price 1890-1907; × season average price 1908-37. Calendar year: Calendar-year production entering into gross income × adjusted (B. A. E.) farm price 1869-1909; × B. A. E. calendar-year farm price 1910-37.

<sup>1</sup> Explanation.—Total Production: Crop year: B. A. E. data. Calendar year: Converted from crop years on the basis of average marketings (Crop Reporting Board files) 1829-22. Average marketings July-December=78 percent, January-June=22 percent rounded off to 80 and 20 percent.

Production entering into gross income: 1909-37, yearly B. A. E. data of ratio gross income÷farm value (see table 16); 1869-1908 average ratio 1909-14 (51.5 percent rounded off to 50 percent).

Farm price: Crop year: 1869-1907, (B. A. E.) Dec. 1 farm price; 1908-37, B. A. E. season-average price. Calendar year: 1869-1909, (B. A. E.) price was raised 5.3 percent. The following States are included: since 1869, Wisconsin, Illinois, New York; since 1890, Minnesota; since 1891, South Dakota. 1910-35: B. A. E. revised calendar year farm price.

Gross income: Same as oats.

<sup>1</sup> Explanation.—Total production: Crop year: B. A. E. data. Calendar year: Converted from crop years on basis of average marketings, 1920-29 (Crop Reporting Board files). Average marketings July-December = 79.7 percent of crop; marketings January-June = 20.3 percent of preceding crop; rounded off to 80 and 20 percent.

Production entering into gross income: 1900-37, actual yearly B. A. E. ratio of gross income ÷ farm value (see table 16). Average ratio 1900-14, 73.7 percent was applied for 1909-1909.

Farm price: Crop year: 1869-1907, B. A. E. Dec. 1 farm price; 1909-37, B. A. E. season average price. Calendar year: 1869-1909, (B. A. E.) price was raised 3.4 percent. The following States are included: Since 1869, Wisconsin, Illinois, New York, Maryland, Virginia; since 1899, Minnesota. 1910-37, B. A. E. calendar year farm price.

Gross income: Same as oats.

<sup>1</sup> *Explanation.*—Total production: Crop year: B. A. E. data. Calendar year: Converted from crop years on basis of marketings (Crop Reporting Board files) 1920-29. Average marketings September-December=55 percent of crop; marketings January-August=45 percent of preceding crop.

Production entering into gross income: 1924-37, actual yearly B. A. E. ratio of gross income-farm value (see table 16); 1869-1918, average ratio 1924-35 (66.2 percent).

Farm price: Crop year: 1869-1907, (B. A. E.) Dec. 1 farm price; 1908-37, B. A. E. season-average farm price. Calendar year: computed by dividing "calendar year gross income" by "calendar-year production entering into gross income."

Gross income: Crop year: 1869-1907, "Crop-year production entering into gross income" X Dec. 1 price; 1908-37, X B. A. E. season average farm price.

Calendar year: As no calendar-year farm price is available, crop-year gross income was converted to calendar-year gross income on the basis of marketings.

<sup>1</sup> Explanation.—Total production: Crop years: B. A. E. data. Calendar years: Converted from crop years on basis of average marketings (Crop Reporting Board files) 1920-29. Average marketings July-December=51.2 percent of crop; average marketings January-June=48.8 percent of preceding crop; both rounded off to 50 percent.

Production entering into gross income: 1924-37, actual yearly B. A. E. data of ratio gross income÷farm value (see table 16); 1869-1923, average ratio 1924-35 (82.8 percent).

Farm price: Crop year: 1869-1907, B. A. E. Dec. 1 farm price; 1908-37 B. A. E. season average farm price. Calendar year: 1869-1909, (B. A. E.) price was raised 4.3 percent. The following States are included: Since 1869, Wisconsin, New York, Maine, Maryland; since 1870, Virginia; since 1876, Minnesota; since 1895, Nebraska. 1910-37, B. A. E. calendar year farm price.

Gross income: Same as oats (1910-37, B. A. E. data, however, not yet available).

<sup>1</sup> Explanation.—Total production: Crop years: B. A. E. data. Calendar years: Converted from crop years on the basis of average marketing (Crop Reporting Board files) 1920-29. Average marketings July-December=70 percent of crop; marketings January-June=30 percent of preceding crop.

Production entering into gross income: 1924-37, actual yearly B. A. E. data of ratio gross income ÷ farm value (see table 16); 1869-1923, average ratio 1924-35 (90.8 percent).

Farm price: Crop year: 1869-1909, B. A. E. Dec. 1 farm price. Estimated for 1876, 77, 78, 81, 92, 93, 94, 98 (no Dec. 1 price available); 1910-37, season average farm price. Calendar year: Computed by dividing gross income by "production entering into gross income."

Gross income: Crop year: Same as oats. Calendar year: computed from crop years according to marketings.

<sup>1</sup> Explanation.—Total production: Crop years: 1869-88, interpolated census figures; 1889-1937, B. A. E. data. Calendar years: converted from crop years on the basis of marketings (Crop Reporting Board files) 1920-29. Average marketings: July-December—87 percent of crop; marketings January-June—13 percent of preceding crop; rounded off to 85 and 15 percent.

Production entering into gross income: 1869-1937, average ratio gross income÷ farm value 1919-35 was applied (91.1 percent). Ratio figures are now available since 1906, but the changes would be insignificant.

Farm price: Crop year: 1902-07, B. A. E. Dec. 1 farm price; 1908-37, E. A. E. season average farm price. Calendar year: 1906-1909, (B. A. E.) calendar-year farm price. The following States are included: since 1869, Wisconsin; since 1891, South Dakota; since 1895, Minnesota; 1910-37, B. A. E. calendar-year farm price.

Gross income: Crop year: As Dec. 1 prices are available only since 1902, no data on "crop year income" could be computed prior to 1902. Calendar-year data were used for crop years, since differences are small in most years.

HAY

Production entering into gross income and gross income are computed from revised B. A. E. estimates of tame-hay production.<sup>25</sup> In B. A. E. gross-income estimates, interstate sales cannot be excluded, since the total income for the United States is derived from State data. For this reason, the B. A. E. ratio of gross income to farm value was not used. Instead, it was assumed that to avoid double counting only that part of the hay crop enters into gross income that is sold as feed for cattle, horses, and mules in cities. According to unofficial estimates by the Department of Agriculture, the hay from 1.6 acres is consumed per cow in cities, from 2.92 acres per heavy horse, from 1.25 acres per light horse and mule.<sup>26</sup> Census data on

<sup>25</sup> UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS, CROP REPORTING BOARD. REVISED ESTIMATES OF TAME HAY ACREAGE, YIELD, AND PRODUCTION, 1866-1928, 56 pp. December 1934). Mimeographed.] REVISIONS, ANNUAL LEGUME CROPS AND ALL TAME HAY \* 1924-1935 \* 7, 29 pp. January 1937. [Mimeographed.]

At first the authors attempted to base the income computation on the production of all hay, that is, tame and wild hay. In the final approach, however, the use of "all hay" production data would not have resulted in any noticeable refinement. For the benefit of those who may be interested in production data of "total hay," a table is added which shows the computation for total hay production, based on B. A. E. data for tame hay, and census data for total hay. Line 3 gives the percentage that had to be added to tame hay for each census year; line 4b gives the corrections to be made in intercensal years.

Estimates of total hay production, crop years

Item	1869	1879	1889	1899	1909	1919	1924	1929
(1) Production:								
(a) All hay . . . million tons	27.32	35.15	66.83	71.11	87.22	90.36	88.38	85.28
(b) Tame hay . . . do	24.50	30.82	50.31	53.95	68.82	76.59	78.93	76.10
(2) Difference between all hay and tame hay . . . million tons	2.82	4.33	16.52	17.13	18.40	13.77	9.45	9.18
(3) Percentage by which all hay is greater than tame hay . . .	11.5	14.8	32.8	31.7	26.7	18.0	12.0	12.1
(4) Percentages to be added or subtracted to item (3) in order to interpolate changes in intercensal years								
Increase or decrease between:								
(a) Census years		3.3	18.0	-1.1	-5.0	-8.7	-6.0	.1
(b) Intercensal years		.33	1.80	- .11	- .50	- .57	-1.20	

<sup>26</sup> These average requirements might have been converted into average production requirements per animal unit, in which case the estimates of production entering into gross income would not have been subject to variations in yield. The authors assumed, however, that although the consumption per animal unit probably does not vary greatly, it is conceivable that sales for ultimate urban consumption may actually respond to variations in yield and prices. Insofar as the estimates of production entering into gross income are unnecessarily influenced by variations in yield, this possible criticism holds only for the period 1893-1913.

cows in cities show that in 1900, 3.7 percent of the tame-hay acreage was needed to feed cattle in cities; in 1920, 3.4 percent. B. A. E. estimates for 1924-30 indicate that this percentage had dropped to 2 in 1930.

BAE 35560

FIGURE 20.—Hay: Production entering into gross income, farm price, gross income, crop years 1869-1937.

To measure feed needs for city horses and mules, B. A. E. estimates of horses and mules in cities were used since 1900. Feed needs for cows, horses, and mules in cities combined amounted to 20.5 percent in 1900 and 3.4 percent in 1930. For the period before 1901, a constant percentage of 20.5 was applied; for 1930-35 the percentage was

kept constant at 3.4; for 1936-37 at 3 percent. As the feed-need estimates per animal are averages expressed in acres, it was not possible to take account of varying yields, and the percentage of tame-hay acreage needed to feed animals in cities was applied to the production of tame hay in order to obtain "production entering into gross income" expressed in tons. In 1920-29 (Crop Reporting Board) 56 percent of the crop-year marketings were marketed from July to December and 44 percent from January to June. In the computation, 55 and 45 percent, respectively, were used. As season average farm prices are available only for recent years, and (because of the rather equal distribution of marketings) production entering into gross income shows notable differences only in years of severe fluctuations in production or prices, gross income for calendar years was computed for all years that do not show notable fluctuations. For these years, calendar-year production and income data were used for crop years also; data for these years are in brackets. Severe changes in production or prices or both from one year to the next prevailed in 1879, 1880, 1888, 1889, 1897, 1898, 1899, 1906, 1907, 1908, 1910, 1911, 1912, 1913, 1916, 1917, 1918, 1919, 1920, 1921, 1927, 1928, 1929-34. Crop-year income in these years was computed from calendar-year income on the basis of marketings. Crop-year farm prices are the quotients of crop-year income and production. For 1869-1909 the (B. A. E.) calendar-year farm price was used. This includes prices from New York, Wisconsin, Maryland, Maine, and Virginia since 1869. As prices from important surplus-producing States are not included, the (B. A. E.) price is 12.4 percent higher than the B. A. E. 1910-14 price. The (B. A. E.) price was adjusted accordingly. For the years since 1910, B. A. E. calendar-year farm prices were employed. As the concept used in the computation of gross income is different from that used by the Department of Agriculture, the authors' estimates are lower, particularly in more recent years (cf. table 5). Production entering into gross income, farm price, and gross income for crop-years 1869-1937 are shown in figure 20 and table 24.

TABLE 24.—Production, price, and gross income: Hay

1 Crop year.

NOTE.—Figures in parentheses indicate that calendar-year production and income data are used for crop years also.

## COTTON

For cotton, B. A. E. crop-year production figures (running bales) were converted to 500 pounds gross-weight bales, 1869-98. Adjustment of running bales was based on net weight of lint per bale as

B. A. E. 35561

FIGURE 21.—Cotton: Production, farm price, gross income, crop years 1869-1937.

given in Bureau of Statistics Circular 32 (25, pp. 8-9). Since 1899, B. A. E. production data (expressed in 500 pounds gross-weight bales) were used. Total production equals production entering into gross income. "Calendar year production" figures for 1869-1909 are computed from crop-year production on the basis of monthly

marketings of farmers, 1924-35 (22, 1935, p. 429). January-July marketings are 20 percent, those from August to December 80 percent of the respective crops. Since 1910, actual sales data of the B. A. E. are available for calendar years.<sup>27</sup> For calendar years 1869-1909 (B. A. E.) calendar-year price was used which is based on New Orleans prices weighted by monthly marketings. For 1910-37 B. A. E. calendar-year farm prices were used in the income, price, and production index computations. Owing to the absence of December 1 prices 1869-76, no gross-income data for crop years could be obtained for these years. Calendar-year data have been used. Production, farm price, and gross income for crop years 1869-1937 are shown in figure 21 and table 25.

## COTTONSEED

Beginning with 1909 for crop years and 1910 for calendar years, income data for cottonseed, as computed by the Bureau of Agricultural Economics were used.<sup>25</sup> For 1874-1908 gross income is computed from the total value of cottonseed as published annually by the Bureau of the Census (21, p. 68). Farm income from cottonseed was 65.1 percent of the total average value of crude cottonseed products 1909-15. This factor (taken as 66.7 percent) was applied in order to convert total value of crude cottonseed products to farm income from cottonseed for 1874-1908. Crop-year income was converted to calendar-year income on the basis of marketings. Cottonseed marketings were assumed to be seasonally equal to cotton-lint marketings. Table 26 contains the data on production, price, and gross income from cottonseed.

<sup>25</sup> See the following for crop years: Agricultural Outlook Charts, 1938, Cotton, October 1937; and Agricultural Outlook Charts, 1939, Oil Seeds, October 1938. For calendar years see reference cited in footnote 27.

TABLE 26.—*Production, price, and gross income: Cottonseed, 1874-1937*

## TOBACCO

Revised crop-year production figures of the Bureau of Agricultural Economics were used throughout for tobacco. For 1869-1908 crop-

year production was converted to calendar-year production on the basis of marketings 1924-29.<sup>29</sup> For 1909-35 actual sales during calendar years have been computed by the Bureau of Agricultural Economics.<sup>30</sup> The authors applied B. A. E. December 1 farm prices

H. A. E. 35562

FIGURE 22.—Tobacco: Production, farm price, gross income, crop years 1869-1937.

1869-1908 for both crop and calendar years. It is not certain whether this price refers to December 1 or to the season average. The (B. A. E.) price is based on export prices. Tests made with export prices

<sup>29</sup> UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. INDEX NUMBERS OF PRICES RECEIVED BY FARMERS FOR FARM PRODUCTS, 1910-35. September 1935. See p. 9. [Mimeographed.]

<sup>30</sup> ———. INCOME PARITY FOR AGRICULTURE, PART I, FARM INCOME, SEC. 2. INCOME FROM TOBACCO, CALENDAR YEARS 1909-37. 41 pp. May 1938. [Mimeographed.]

and the aforementioned B. A. E. price series demonstrated that the latter conforms much better to the movement of production and the business situation. Gross income is the product of total crop-year production and B. A. E. farm price for crop years, and of calendar-year production and B. A. E. farm price, 1869-1908. Since 1909, the B. A. E. season-average prices were applied for crop years and B. A. E. calendar-year income data (product of sales and calendar-year farm price) for calendar years. Production, farm price, and gross income for crop years 1869-1937 are shown in figure 22 and table 27.

## RICE

Production data for rice are those of the Bureau of Agricultural Economics throughout; data before 1909 are unrevised.<sup>31</sup> Farm prices are available only since 1909; for earlier years the New York wholesale price is the only consistent series. Although the New York wholesale price does not fluctuate in complete accordance with farm prices, the major fluctuations are indicated. B. A. E. farm prices 1909-13 amounted to 31.9 percent of the New York wholesale price after the price per 100 pounds had been converted to the price per bushel. Since in 1909 and 1910 this percentage was slightly below 30, a conversion factor of 30 was applied to adjust for the difference between New York wholesale prices and farm prices. Marketings from August to December were 62 percent of total crop-year marketings, 1926-35 (*24, 1937, p. 81*), crop-year production was converted to calendar-year on the basis of 60 percent for August-December and 40 percent for January-July. Calendar-year production multiplied by calendar-year price gives calendar-year income. After 1909, crop-year production was multiplied by crop-year price, and the result converted to calendar year income by using the 60-40 proportions. B. A. E. income data 1924-33 show that gross income is 95.02 percent of farm value. As the data before 1909 are merely approximations, they were not adjusted; farm values since 1909 were lowered 5 percent.

Comparisons with census data indicate that the conversion factor based on the relation of the New York wholesale price to the farm price works out satisfactorily; the authors' calendar-year income for 1899 is \$6.3 million, the crop-year income of the census year 1899, \$6.1 million. Production, farm price, and gross income for calendar years 1869-1937 are shown in figure 23 and table 28.

<sup>31</sup> For 1890-1903, Bureau of Statistics, Circular 34 (*26*), barrels converted to bushels (3.6 bushels = 1 barrel); 1904-08, Technical Bulletin 267 (*4, p. 40*); since 1909 (*24, 1937, p. 79*).

## DRY EDIBLE BEANS

For dry edible beans, production figures 1879-1913 are interpolated census figures; before 1879 they are extrapolated trend (1880-1900) data. Owing to a complete lack of evidence concerning the move-

B. A. E. 35584

FIGURE 24.—Dry beans: Production entering into gross income, farm price, gross income, calendar years 1869-1937.

ment of production between census years, straight-line interpolation had to be resorted to. In view of the relative unimportance of the crop during these years, this device will not affect the total for the income subgroup or the grand total noticeably. For the years since

1914, B. A. E. production data were used.<sup>32</sup> Crop-year production was converted to calendar-year production on the basis of marketings (80 percent between September and December, 20 percent between January and August).

The (B. A. E.) farm price since 1869 covers New York, Wisconsin, and Maine. It had to be lowered 13 percent to make it comparable with the B. A. E. farm price since 1910. Farm value before 1924 was computed from production and adjusted farm prices. Gross income amounts to 91.5 percent of farm value, according to B. A. E. data on farm value and gross income 1924-35. Since 1924, B. A. E. crop-year farm income was converted to calendar-year income on the basis of marketings. Production, farm price, and gross income for calendar years 1869-1937 are shown in figure 24 and table 29.

## BEET SUGAR

Data on production of sugar beets, average prices per ton of beets to the producer, and on the farm value of sugar beets have been published since 1911 by the Bureau of Agricultural Economics (22, 1923,

B. A. E. 35565

FIGURE 25.—Beet sugar: Production entering into gross income, farm price, gross income, calendar years 1869-1937.

p. 842; 1933, p. 484) and in Agricultural Statistics (24, 1937, p. 107). Before 1911, production figures are available only for "raw sugar from sugar beets" (22, 1923, p. 845); revised data of Bureau of Agricultural Economics and Bureau of Statistics Bulletin 66 (27) were

used. The only consistent series on prices is the New York wholesale price of raw sugar. Applying this wholesale price to raw sugar production from beets, the authors found that farm value computed as the product of "sugar beets produced" and "farm price of sugar beets" amounted to 44.4 percent of the value based on New York wholesale prices and production of "raw sugar from beets" in the average 1911-17. Before 1911, gross income from sugar beets was therefore computed as 45 percent of the value obtained by multiplying raw sugar produced from sugar beets by the New York wholesale price. This percentage, derived from the comparison of B. A. E. data on the farm value resulting from the sale of sugar beets and the value of raw sugar at wholesale prices, corresponds to the figure that is to be expected, according to the contracts of beet growers with the sugar manufacturers. These contracts provide that the growers receive one-half of the value of the manufactured product at wholesale prices after deduction of taxes. Comparison with census figures shows that this computation of income data yields close approximations to census estimates. The estimates based on the described method are: For 1899, 3.5 million dollars as against a census estimated of 3.3 million dollars; for 1909, 19.8 million dollars instead of a census figure of 19.7 million dollars. Production entering into gross income, farm price, and gross income for calendar years 1869-1937 are shown in figure 25 and table 30.

## CANE SUGAR

For cane sugar, B. A. E. data on production, season-average farm prices, and farm value of sugarcane are available since 1919 (24, 1937,

B. A. E. 35566

FIGURE 26.—Cane sugar: Production entering into gross income, farm price, gross income, calendar years 1869-1937.

*p. 111*). Before 1919, only production data on raw sugar from sugarcane and New York wholesale prices of raw sugar are available.<sup>33</sup> A high correlation exists between the uncorrected farm price of sugarcane

<sup>33</sup> None of the early standard publications (3) contain data on farm prices. (Data furnished by the Bureau of Agricultural Economics.)

and the New York wholesale price of raw sugar. There is no way of checking the assumption that this relationship results in a similar relationship between farm income from sugarcane computed on the basis of wholesale prices and of farm prices, respectively, as was found in the case of beet sugar. The authors' income computation assumes that cane growers receive 45 percent of the income based on wholesale prices, as they do from beet sugar. Since this computation was linked to actual income after 1919 and since the cane-sugar price fluctuates in accordance with the wholesale price, the result is probably a fair representation of actual farm income. No checks with census data are possible because the census figures on production and income from sugarcane combine sugar and sirup. Production entering into gross income, farm price, and gross income for calendar years 1939-1937 are shown in figure 26 and table 31.

ORCHARD FRUITS

Apples, peaches, pears, prunes, plums, and cherries are included under orchard fruits. Since 1924, B. A. E. "actual production" and

season-average farm price were used for each fruit. As data on plums, prunes, and cherries are not available from 1919 to 1923, 11 percent was added to the income from apples, peaches, and pears—the percentage that cherries, plums, and prunes were of the income from these three fruits in 1924 and 1925.

*Production figures* for apples are available yearly since 1889;<sup>34</sup> for peaches and pears yearly since 1909. Census figures on the production of individual fruits were not published before 1889. In the 1880 census, reference is made to a special report by a Mr. Dodge which should give information about production in 1879, but the Bureau of the Census does not have this report and doubts whether it was ever published. The censuses since 1899 report both the total value of these fruits (total orchard fruits) and the total production in bushels. For 1889, total production alone is given; the earlier censuses contain "total value" alone. Owing to the extreme fluctuations in yield of the various fruits, the actual crops of the census years cannot be used to indicate the trend of production; consequently an interpolation on this basis would be meaningless. Fortunately, the Crop Reporting Board has published data on yields since 1866, showing separately the condition of the apple and peach crops expressed as a percentage of full yield.

Consistent price data can be computed for apples alone. The Bureau of Agricultural Economics calculated a weighted-average farm price for Maryland and Virginia combined (unpublished); furthermore, monthly prices for New York are available. Marketings in New York State (measured by earlot shipments) from September to December are 63.5 percent of total marketings (*22, 1924, p. 666*) (based on marketings 1917-23). The authors computed a weighted average price for these 4 months, the weights based on marketings in each month. This average weighted New York farm price for apples was combined with the (B. A. E.) weighted-average farm price for Virginia and Maryland, New York having a weight of 2 as against 1 for Virginia and Maryland together (basis: census data on production in these States). This computed apple price was used to estimate the price of orchard fruits 1869-1909, when B. A. E. season-average farm prices begin.

The authors' first approach to estimating income from orchard fruits was to use production of apples and estimate production of other fruits. Owing to lack of adequate basic data, this procedure was not satisfactory and the following method was used. It should be clear, however, that even income estimates for very recent years need revision. Therefore, the estimates can merely be regarded as the best available approximations.

Table 32 shows full crop production for census years. This computation was necessary to obtain the production trend of total orchard fruits. The censuses 1890-1920 contain production figures for "all orchard fruits." In order to adjust for fluctuations in yield, the combined data (weighted) on the condition of the peach and apple crops (*22, 1923, pp. 732, 746*) (expressed as a percentage of full yield) were applied as correction factors. Thus, the authors obtain pro-

<sup>34</sup> YOUNGMAN, W. H., comp. STATISTICS AND CHARTS OF THE APPLE INDUSTRY. U. S. Bur. Agr. Econ. 99 pp. 1930. [Mineographed.]

UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. REVISED PRODUCTION OF APPLES, PEACHES, PEARS, GRAPES AND CHERRIES, 1919-1935. June 28, 1937. [Mineographed.]

— Agricultural Outlook Charts, October 1937, Fruits and Nuts.

duction (in bushels) of "all orchard fruits" upon the assumption of constant crop conditions (full yield) for census years; through straight-line interpolation they obtain the yearly production figures upon the assumption of full yield (table 32). As these data can be adjusted for annual fluctuations in yield, straight-line interpolation is warranted.

TABLE 32.—*Computation of trend data of the production of all "orchard fruits"*  
[Based on census quantities]

Item	1880	1899	1909	1919
Actual production of all orchard fruits.....million bushels..	187.2	212.4	214.7	217.0
Yield of apples and peaches.....percent	68.8	38.0	50.3	53.8
Production of all orchard fruits assuming full yield.....million bushels..	267	558	430	403
Relatives (1899=100).....percent	42.8	100.0	77.0	72.0

The censuses of 1870, 1880, and 1890 contain data on the value of all orchard fruits (table 33). These values were corrected for the fluctuations in prices by expressing the values in constant prices (1899=100). Values at 1899 prices are of actual crops. To arrive at "values for full crops" in the respective years, the data were corrected for fluctuations in yield. Thus, the full crop of 1899 (558 million bushels) would have had a value of \$220.5 million. On the basis of this relationship between full crop in millions of bushels and its value at 1899 prices, the 1879 crop was 45.1 percent of the 1899 crop; that of 1869, 13.5 percent. These trend data are interpolated to arrive at yearly production data upon the assumption of full yield. The interpolated figures are then adjusted for the yearly fluctuations in yield. The adjusted data represent the estimated actual crops of all orchard fruits 1869-1919.

The use of prices of apples instead of prices of peaches, pears, etc., for orchard fruits other than apples would result in undervaluation. The authors found that in 1909 the volume of fruits other than apples constituted 37 percent of that of all orchard fruits but the value was 41 percent of the total, which means that the price of fruits other than apples was 10.7 percent higher than the price of apples.

TABLE 33.—*Computation of trend data of the production of "all orchard fruits"*  
[Based on census values]

Item	1899	1879	1869
(1) Actual values of all orchard fruits.....million dollars	83.8	50.9	47.3
Apple price:			
(2) Per bushel.....cents	52	43	83
(3) Index (1899=100).....percent	100	82.7	159.6
(4) Value of all orchard fruits at 1899 prices.....million dollars	83.8	61.6	29.6
(5) Yield of actual crop, percentage of "full crop".....percent	38.0	62.3	99.2
(6) Value of all orchard fruits at 1899 prices assuming full yield.....million dollars	220.5	99.4	29.8
(7) Relatives of item (6.) 1899=100.....percent	100	45.1	13.5
(8) Estimated production of all orchard fruits assuming full yield.....million bushels	558	251	75.5

For 1919 this percentage was 11.7. Assuming that before 1889 the crop of fruits other than apples was 30 percent of the apple crop; from then to 1918, 50 percent, and thereafter 66 percent,<sup>35</sup> that is, that the

<sup>35</sup> The ratio for 1909 is 65.1 percent, according to census data. From what little information there is prior to 1909, the production trend of fruits other than apples was steeper than that of apples. The ratios indicate the trend, but their actual magnitude is more or less arbitrary. The possible error would not affect the income estimate appreciably, however.

crops of fruits other than apples were 23, 33, and 40 percent of the crop of total orchard fruits, the following percentages were added to the value of orchard fruits based on apple prices: 1866-89, 2.5; 1899-1918, 3.5, in order to correct for the higher value of fruits other than apples.

The price data, corrected for the price differential of fruits other than apples which include the three States only, are apparently not representative for the total United States. The census gives for some years both value and volume data for total orchard production. According to these data, the price series here used is too high and calls for downward adjustments: 26.3 percent in 1899 and 22.6 percent in 1909.<sup>36</sup> Therefore, they corrected the income data, obtained by multiplying actual production by this computed price, by lowering the values 26 percent from 1869 to 1899, and 23 percent from 1900 to 1908. Since 1909, the B. A. E. weighted season-average price of apples was used as given in publications of the United States Department of Agriculture. This price had to be raised 3.5 percent from 1909 to 1918 to adjust for the difference in the price of apples and of fruits other than apples.

The income data from orchard fruits for crop years (June-May) that resulted from these computations were then converted to calendar years on the basis of marketings. Marketings of apples from June to December amounted to 81.5 percent of the 1917-23 total marketings in the United States (22, 1924, p. 667). The crop of other orchard fruits is marketed during the calendar year. To take into account the changing importance of apple production, the following marketing percentages were computed: 1869-1888: 85 percent, June-December, 15 percent, January-May; 1889-1918: 90 percent, June-December, 10 percent, January-May; 1919-35: 95 percent, June-December, 5 percent, January-May. Calendar-year income for 1870 was thus computed by adding 15 percent of the 1869 crop-year income (income January-May 1870) and 85 percent of the 1870 crop-year income (June-December 1870).

Income in 1882 and 1895 seems to be exceedingly high, because large crops did not result in low prices; that is, prices in all three States were high despite large crops. Production in these States amounted to 23 percent of total United States production in 1909. The movement of the general price level does not explain the coincidence of large production and high prices, nor does the export situation give the clue to this unusual supply-price relationship. Exports of fresh apples during the crop year 1882 were about 5 percent of production and twice those in the preceding year, but prices were about 10 percent higher; dried-apple exports were more than 3 times as large with prices unchanged. Also during the year preceding and the year following 1895 exceedingly large quantities of both fresh and dried apples were exported. It does not seem reasonable that the small proportion of the crop exported at higher prices is a sufficient explanation for the high domestic prices in the face of high production in these 2 years. Production, farm price, and gross income for crop years 1869-1937 are shown in figure 27 and table 34.

<sup>36</sup> This price adjustment is not altogether satisfactory, as no comparisons for census before 1899 can be undertaken. But there is no other possible way to evaluate the differential between this computed price and other prices for the total United States.

## CITRUS FRUITS

Production estimates for citrus fruits made by the Bureau of Agricultural Economics begin in 1919. For the earlier years, production had to be computed from shipments and returns gathered by the California Fruit Growers Exchange and the Florida Citrus Exchange. Total shipments from California are available since 1886 (10, p. 70), from Florida (30) since 1884. The California data are given in number of cars, those for Florida in number of boxes; the number of boxes per car ranged from 374 to 396 between 1903 and 1913. Boxes were converted into cars on the basis of 374 boxes per car, before 1909. (W. H. Shaw of the National Bureau of Economic Research found later, that annual data on boxes per car are available. The results would not differ greatly, however.) Since 1895, f. o. b. returns of the California Fruit Growers Exchange have been published together with the percentage that exchange shipments were of total shipments. This percentage was applied in order to obtain f. o. b. returns for the entire State 1895-1909. Florida prices were assumed to equal California prices during this period; thus, the percentage that Florida shipments were of California shipments in each year was applied to the f. o. b. returns for California to obtain f. o. b. returns for Florida. This may result in a slight overvaluation, but between 1895 and 1908 the ratio of Florida shipments to California shipments fluctuated only between 4 and 30 percent; in most years the difference would be insignificant. Since 1909 separate data on f. o. b. returns for California and for Florida are available.<sup>37</sup> The f. o. b. returns include the costs of picking, hauling, packing, selling, and advertising. In accordance with the income concept used throughout this study, picking and hauling costs should be added to the price of the fruit on the tree in order to obtain gross income; selling and advertising costs, however, must be deducted from the f. o. b. income. Table 35 indicates the ratios of picking and hauling costs to the cost of the "fruit on tree" and of the gross-income items (price of "fruit on tree" plus costs of picking and hauling) to the f. o. b. income. The authors therefore deducted 27.9 percent from f. o. b. income in order to obtain gross income. The income data that resulted from using adjusted f. o. b. returns check with census figures for the early years and with B. A. E. gross income after 1919. For the years since 1919 B. A. E. production and farm-price data were used.<sup>38</sup>

The conversion from crop to calendar-year was based on marketings for more recent years. Carlot shipments of citrus fruit November-December 1924-28 were 23.9 percent, those from January to the end of the crop year 76.1 percent, of total crop-year shipments. Crop-year income was converted to calendar-year income by distributing income 25 and 75 percent respectively.<sup>39</sup> Gross income could not be computed before 1895,<sup>40</sup> because of the lack of price data. Since the census value of oranges for 1889 is \$6.6 million, it seems probable that gross income in the 1880's may have fluctuated around \$5 million. Production, farm price, and gross income for crop years 1869-1937 are shown in figure 28 and table 36.

GRAPES

For grapes, production data 1919-37 are B. A. E. figures for the United States (24, 1938, p. 190), those for 1899-1918 are based on census data interpolated by Shear.<sup>41</sup> The interpolations are based on the annual condition of the grape crop as reported by the then Division of Crop and Livestock Estimates. "Full crops" for census years

<sup>41</sup> On file in the Bureau of Agricultural Economics.

were computed by using these yields and the trend of the full crop thus obtained was interpolated by applying annual yields; in addition, the result was checked with more detailed information about the

B. A. E. 35569

FIGURE 29.—Grapes: Production, farm price, gross income, calendar years 1869-1937.

development of the grape crops in California. The data for 1889-98 were computed by straight-line interpolation, as no annual series are available.

Farm prices have been published by the Bureau of Agricultural Economics since 1924. From 1919 to 1923 California farm prices

(15, p. 122) were raised 10 percent to make them comparable with B. A. E. farm prices. For 1917 and 1918, only the f. o. b. price of 4 wine varieties (15, p. 120) is available; this price was linked to the prices for the later years. From 1887 to 1916 prices of sweet-wine grapes<sup>42</sup> were linked to the more recent price series by raising them 180 percent. These prices are published only in graphic form. In view of the wide fluctuations in prices of the various varieties, it is not possible to state that this price series is representative. However, a comparison of census data with these estimates indicates that the adjusted prices used in the computation are very close to the actual prices. According to these estimates, income amounted to 15.1 million dollars in 1899, 22.0 million dollars in 1909, and 95.4 million dollars in 1919, as against census estimates of 14.1, 22.0 and 95.6 million dollars in the corresponding years.

Harvesting and marketing of grapes falls within the calendar year, therefore no conversion is necessary.

Production, farm price, and gross income for calendar years 1869-1937 are shown in figure 29 and table 37.

TABLE 37.—Production, price, and gross income: Grapes, calendar years, 1889-1937

## PEANUTS

For peanuts, farm-value and gross-income data of the Bureau of Agricultural Economics start in 1924, production data in 1916.<sup>43</sup> Census figures on the production of peanuts harvested for nuts have been published since 1889 in bushels. As (B. A. E.) farm price refers to pounds, the census production data were converted into pounds. The conversion factor from bushels to pounds is different

<sup>42</sup> SHEAR, S. W., and PEARCE, G. G. SUPPLY AND PRICE TRENDS IN THE CALIFORNIA WINE-GRAPE INDUSTRY. Giannini Found. Agr. Econ. Mimeographed Rpt. 34, Pt. 2. Berkeley, June 1934. See Chart 5.

<sup>43</sup> Production data, 1916-21 (24, 1924, p. 793). For data since 1921, see the following: UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS, Agricultural Outlook Charts, 1938, Fruits and Nuts.

for the various varieties of peanuts: For Virginia growths it is 1:22, for runners 1:28, for Spanish 1:30. Virginia growths declined in relative importance. At present, it is about half of the other two

B. A. E. 35570

FIGURE 30.—Peanuts: Production, farm price, gross income, calendar years 1869-1937.

combined. Therefore a weight of 1 was applied for Virginia and of 2 for the others in the computation of the conversion from bushels to pounds after 1915. For 1909-14 the weights are 1 and 1; before 1909, 2 and 1. Thus the conversion before 1909 is on the basis of 24 pounds to a bushel; for 1909-14, 26 pounds; and after 1915, 27 pounds.

Census data on production were interpolated to get yearly production figures 1889-1915. The data for 1869-88 are extrapolated trend figures of census data. The (B. A. E.) farm price refers to Virginia peanuts and had to be raised 29.2 percent to be comparable with the more inclusive B. A. E. farm price. Crop-year production was converted to calendar-year production on the basis of marketings (80 percent August-December, 20 percent January-July). As the census data refer to production of peanuts harvested for nuts, farm value is equal to gross income. For 1916-23, B. A. E. production figures for total peanuts were multiplied by farm prices to get farm value. Between 1924 and 1935 farm income represented 60.5 percent of the average farm value. Farm income 1916-23 was therefore assumed to be 60 percent of farm value. After 1924, crop-year gross income as computed by the B. A. E. was converted to calendar-year income on the basis of marketings.

Production, farm price, and gross income for calendar years 1869-1937 are shown in figure 30 and table 38.

TABLE 38.—Production, price, and gross income: Peanuts, calendar years 1870-1937

DAIRY PRODUCTS

Income from dairy products is computed from B. A. E. data <sup>44</sup> on the production of the principal manufactured dairy products since

<sup>44</sup> For butter data see the following: UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. THE DAIRY SITUATION. DS-30, 19 pp., illus. February 1934. [Mimeographed.]  
 For data on condensed and evaporated milk see: UNITED STATES BUREAU OF AGRICULTURAL ECONOMICS. THE DAIRY SITUATION. DS-65, 12 pp., illus. April 16, 1937. [Mimeographed.]  
 For a detailed explanation of the methods used in arriving at the estimates, see VIAL, E. E. PRODUCTION AND CONSUMPTION OF MANUFACTURED DAIRY PRODUCTS (29).

1869, and on B. A. E. tentative revisions and interpolations of census figures for milk production (fig. 31).<sup>45</sup>

The B. A. E. production series for processed dairy products contains separate data for butter (farm and factory), cheese, and condensed and evaporated milk production. These production figures were used in their original form as compiled by the Bureau of Agricultural Economics.

The (B. A. E.) farm price of butter includes farm prices of the following States: since 1869, New York, Wisconsin, Maryland, Virginia, Maine, Illinois; since 1895, Nebraska. These States seem to be representative, since for 1910-14 the farm price derived from them is equal to the B. A. E. weighted farm price; moreover, they produce a large part of total production. Gross income from butter production is computed by multiplying farm price by butter production (table 40).

Prices of cheese had to be computed on the basis of New York (13) and Wisconsin (11) farm prices. New York and Wisconsin together produced 80 percent of the manufactured, and 45 percent of farm cheese in 1870; 70 percent of total cheese in 1900; and 72 percent of total cheese in 1930. The weighted-average Wisconsin-New York cheese price may therefore be taken as representative. The prices were weighted according to census production in 1870, 1900, and 1930 in New York and Wisconsin. In 1910, New York production was about 10 times greater than Wisconsin; in 1900, 1½ times greater; and in 1930 production in Wisconsin was 4 times greater than production in New York. Between these weights interpolations were made for 5-year periods. The Wisconsin farm prices for cheese are given in cents per pound, the New York price was computed on the basis of the butter price; for 1850-1910, 2.2 pounds of butter were equal in value to 1 pound of cheese according to computations of Ronk (13). The value equivalents are given for 10-year periods, during which they fluctuated very little. These variable conversion factors were used to compute cheese prices from butter prices in New York. The weighted-average cheese price of New York and Wisconsin was multiplied by cheese production to obtain income from cheese production (farm and factory) (table 41).

The price of condensed and evaporated milk is equal to about one-tenth of the butter price, this being the conversion factor used by the Bureau of Agricultural Economics. Income from condensed and evaporated milk was obtained by multiplying production by price<sup>46</sup> (table 42). Aggregate income from butter, cheese, and condensed and evaporated milk production represents total income from manufactured dairy products, farm and factory.

During recent years total milk production has fluctuated less than production of manufactured dairy products. Therefore, milk utilization in fluid form was assumed not to be a constant percentage of manufactured dairy products (expressed in milk equivalent) but the difference between B. A. E. estimates on total milk production and production of total processed dairy products expressed in milk equivalents. The B. A. E. revisions of the census figures on total milk

<sup>45</sup> These data have been published in chart form only and may be subject to later revisions.

<sup>46</sup> The authors' income figures for census years are considerably lower than the cost of milk used in the manufacture of condensed milk as given in the Census of Manufacturers. These costs amounted to \$1.3 million and \$1.7 million respectively in 1890 and 1900, whereas the authors' corresponding income figures from evaporated milk are \$0.5 million and \$4 million.

production start with 1899. These data and the smoothed series of production data of processed dairy products have almost a parallel movement. Consequently, the latter series was used and the series of total milk production was extrapolated from 1899 to 1869 on the basis of the actual relationship after 1899.

It proved impossible to compute gross income from fluid milk by applying prices of fluid milk. Neither the Wisconsin nor the New York series of fluid-milk prices is consistent during the period in question. The Wisconsin series at times represents wholesale and at other times retail prices. New York farm prices of milk for most of the years covered, are actually prices for milk sold at retail. Their use would therefore result in higher income than if computed at local farm prices. The B. A. E. computations of gross income from dairy production for 1924-37 show that the use of retail prices for the part of the fluid milk that has actually been retailed raises the total income from dairy production about 10 percent above the computation in which also the part of the milk that has been retailed was evaluated at wholesale prices. This means that the use of such unsatisfactory data on milk prices could only result in farm-income data for fluid milk that were far above actual income. On the other hand, fluctuations in milk prices seem to correspond closely to those in butter prices. (This conclusion is based on a comparison between New York State milk and butter farm prices.) Ronk states that for 1871-1930, 5.6 pounds of butter were on the average equal to 100 pounds of fluid milk, the slight changes over the entire period may be due to the incompleteness of the milk-price data. This factor, 5.6, is about the same as the usual conversion factor from butter to milk volume.

It was assumed, therefore, that the income from a certain quantity of milk would be about the same whether it resulted from the sale of fluid milk or the production of butter. Apparently, during most of the period covered, fluid milk held a slight premium over manufactured dairy products, so that the use of the price of manufactured dairy products results in a small undervaluation. For this reason the part of the milk that was fed to calves and does not enter into gross income was not deducted. This percentage fluctuated between 2 and 3, and it seems safe to assume that the omission of this correction approximately balances the undervaluation resulting from the use of manufactured dairy prices instead of fluid-milk prices. However, 3 percent of total milk production was deducted to adjust for the waste factor. This percentage is derived from recent census data; it is impossible to check whether this ratio holds also for early years. Gross-income data for fluid milk are shown in table 43.

The differences between the production of total manufactured dairy products expressed in fluid-milk equivalents and of total milk production for each year were thus computed as a percentage of manufactured dairy production, and this percentage was added to the income from manufactured dairy products in order to obtain income from total dairy production. An attempt was made to check the B. A. E.-N. B. E. R. gross-income data by comparing income derived from the production of total dairy and from manufactured milk-production data on the one hand and the butter price and the condition of the feed crop (of the preceding year) on the other hand. This check led to the following corrections: In 1882, the extrapolated figure of total milk

production is undoubtedly too high. The yield of the corn crop in 1881 was extremely low—19.8 bushels as against 27.3 in 1880 and 26.5 in 1882. This is expressed in the butter price of 1882, which was 24 cents as against 21 in 1881 and 20 in 1883. The extrapolated figure of total milk production for 1882 would indicate that fluid-milk production amounted to 83 percent of that of manufactured dairy products expressed in milk equivalent, as compared with about 65 percent in the preceding and following years. This percentage was therefore corrected from 83 to 65, according to the percentages in the immediately preceding and following years, which lowers the income figure correspondingly.

Similarly, the extrapolated data of total milk production from 1891 to 1894 seem too high for the same reason. The yield in 1890, 1892, 1893, and 1894 was low; the authors' fluid-milk production data (expressed as a percentage of manufactured milk) between 1891 and 1894 would again be too high and were also lowered on the basis of the percentage data of the preceding and following years. The yield of corn in 1901 was 18.2 bushels as against 28.1 in 1900, and 28.5 in 1902. The butter price rose from 17 cents in 1901 to 19 cents in 1902. The interpolated 1902 production figure of fluid milk would be too high—83 percent of the production of manufactured dairy as compared with 61 percent in 1901 and 75 percent in 1903. The figure was corrected accordingly.

Table 39 compares the B. A. E.-N. B. E. R. gross-income data from total dairy production with the preliminary estimates of the Department of Agriculture. Though the estimates are based on entirely

1933.....	959	1,263	76.72
1934.....	1,067	1,478	72.19

different methods, they are fairly close until 1928. The differences of between 0.3 and 6.6 percent are probably due mainly to the fact that the B. A. E.-N. B. E. R. series is based on prices of manufactured dairy products instead of fluid-milk prices and the price differential is assumed to be compensated for by the inclusion of milk fed to calves. In 1929 the Department of Agriculture changed its methods. Retail prices were applied to the estimated part of milk production that was marketed at retail. The increase in the differences between the two estimates indicates that this part has been rising since 1929. As it is

REVISED 1940. U.S.D.A. TECHNICAL BULLETINS. ST. PETERSBURG, FLORIDA  
GROSS FARM INCOME AND INDICES OF FARM PRODUCTION AND PRICES IN  
STRAUSS, F. BEAN, L. H. —

impossible to estimate the quantity of milk sold at retail for the years before 1929, the authors carried the estimates forward by using manufactured dairy prices as was done for the period before 1929, which

B. A. E. 35805

FIGURE 31.—Dairy products: Production, farm price, gross income, calendar years 1869-1937.

explains most of the increasing discrepancy between the two estimates. Production, price, and gross income from total dairy products are shown in figure 31 and table 44.

## POULTRY AND EGGS

For 1925-37, recently revised estimates of the Bureau of Agricultural Economics on the number of chickens sold and consumed in farm households, and on the number of eggs sold and consumed in farm households have been used in the income computation for poultry and eggs.<sup>47</sup> The sales and home-consumption data are given in number and were converted to pounds on the basis of 3.7 pounds per chicken. Farm price of chickens and of eggs, 1909-37, are also B. A. E. revised figures (*23 v. 13, p. 46; 24, 1938, p. 371*) but differ slightly from those given in the aforementioned source which shows separate price data for chickens and eggs sold and consumed in farm households, owing to the different weighting of State prices for these two categories. As this segregation is not available for earlier years, prices for chickens and eggs sold were applied throughout. The differences are slight.

Data on chickens for earlier years are derived from census data. As is well known, these census data greatly underenumerate production. The Department of Agriculture states that

while reasonably complete for numbers of farm poultry on hand at the time of taking the census, it seems evident that they are low in the reported number of eggs laid and sold, and of chickens raised and sold during the previous year. These production and sales figures are not enumerations of facts within the immediate knowledge of the farmer, but merely a record of his judgment or best guess, or that of his wife, or of the enumerator. Omissions and understatements under these conditions are to be expected.<sup>48</sup>

Using the best supporting evidence then available, the Department of Agriculture attempted to adjust the census data for errors resulting from differences in the date on which the enumeration was made and from differences in the census schedule. These adjustments led to upward corrections for the number of chickens on hand of 38 percent in 1880, 12 percent in 1900, 15 percent in 1910 and to a reduction of 25 percent of the census figure for 1890.<sup>49</sup> There exists a nearly constant ratio between the number of chickens on hand and the number raised for the census years 1910, 1920, and 1925, namely 143.0, 142.1, and 144.1 percent. The adjusted census figures, 1880-1910, of the number of chickens on hand were therefore converted to "number of chickens raised" by applying the approximate ratio figure, 145 percent, for 1910-25. As indicated, these estimates attempt to take care of the aforementioned inaccuracies in the census data. The most recent estimates by the Department of Agriculture utilized additional information as secured by extensive experimental enumerations by the field statisticians of the Crop Reporting Board, by data on rural and urban consumption, and by an analysis of data for sample flocks. This improved method resulted in the necessity of increasing the original estimates of the number of chickens raised 11.6 percent in 1930 and 11.8 percent in 1935. It was assumed that a similar ratio of omission was prevalent in earlier years; therefore the adjusted census figures on number of chickens raised were marked up 10 percent. The revised data, 1925-37, indicate that the number of chickens lost amounts to about 8 percent of the number raised. The revised data

FIGURE 32.—Chickens: Production, farm price, gross income, calendar years 1869-1937.

live weight of the chickens sold and consumed on farms was estimated to have decreased from 4 to 3.7 pounds between 1900 and 1910. The (B. A. E.) farm price for chickens was applied from 1869 to 1908. It includes the following States: Since 1859, New York, Wisconsin, Maine, Illinois; since 1873, Maryland; since 1883, Virginia. It had to

be lowered 9.6 percent to make it comparable with the B. A. E. price for the United States. Production, farm price, and gross income for calendar years 1869-1937 are shown in figure 32 and table 45.

Census data on egg production are even more strongly affected by the diverse dates of the census enumeration. From a comparison of census figures with estimates of the Department of Agriculture, which attempt to adjust for this variation, it appears that censuses taken in January show by far the largest underenumeration. It is impossible to correct for this factor exactly. But based on recent experience the January enumerations were raised 30 percent, on the basis of the 1935 census, the April enumerations 20 percent, and the June enumerations 15 percent. This adjustment is not entirely satisfactory, but as no additional evidence is available, it results in far closer approximations than would the use of census data. Annual data were procured by straight-line interpolation. For 1869-1908 the (B. A. E.) farm price of eggs was used. It is based on prices for the following States: Since 1869, New York, Wisconsin, Maine, Maryland, Virginia; since 1871, Illinois; since 1891, South Dakota; since 1895, Nebraska.

Production, farm price, and gross income for calendar years 1869-1937 are shown in figure 33 and table 46.

WOOL

Before 1909 production data for wool, as published by the National Association of Wool Manufacturers, were used (*5, v. 1, p. 244; 1, p. 18*). Apparently the Bureau of Agricultural Economics considers this series the most reliable of those available (*24, 1937, p. 280, footnote*). Since 1909 revised production, price, and income data of the Department of Agriculture could be utilized.<sup>30</sup> The (B. A. E.) farm price was raised 16.9 percent to make it consistent with the B. A. E. farm price.

Production, farm price, and gross income for calendar years 1869-1937 are shown in figure 34 and table 47.

<sup>30</sup> Published in the meantime in the series Income Parity for Agriculture.

CATTLE

Department of Agriculture estimates of slaughter are available since 1899 (24, 1938, p. 293). The Department of Agriculture derives total slaughter (number of head) by estimating four kinds of slaughter separately: Federally inspected, noninspected wholesale, retail, and farm slaughter. By adjusting for the yearly variations in live weight per head of these four kinds of slaughter, a consistent slaughter series, expressed in pounds of live weight, is obtained. The (B. A. E.) calendar-year farm price of beef cattle includes the following States and cities: since 1870, Iowa; since 1891, South Dakota. The (B. A. E.) price is 0.7 percent below the B. A. E. average price 1910-14 and was adjusted accordingly. Gross income from cattle since 1899 was computed by multiplying B. A. E. estimates of slaughter by the (B. A. E.) adjusted farm price of beef cattle.

Slaughter for 1869-98 was estimated on the basis of inventories of cattle on farms. Fortunately, the Department of Agriculture recently completed its revised estimates of annual livestock inventories since 1867<sup>51</sup> which are undoubtedly a marked improvement over

<sup>51</sup> U. S. Bureau of Agricultural Economics. LIVESTOCK ON FARMS, JANUARY 1, 1867-1919. REVISED ESTIMATES, NUMBER, VALUE PER HEAD, TOTAL VALUE, BY STATES AND DIVISIONS. 137 pp. January 1932. (Miscographed.)

previous estimates. The estimates of "cattle inventories" include "all cattle on farms," therefore it was necessary to obtain separate series for inventories of "cattle 1 year and over" and for "calves under 1 year."

The Censuses of Agriculture for 1910, 1920, and 1935, taken as of January 1, show 23.6, 23.2, and 23.6 percent of calves under 1 year (percentage of total cattle). The indications are—according to census data for earlier years adjusted for differences in the date of enumeration—that this ratio has not varied notably. A series of "inventories of cattle 1 year and over" was computed by subtracting 23.5 percent from the "inventories of all cattle on farms."

Some experts stress the nearly constant relationship between "inventories of cattle on farms" and slaughter. The 1900 Census of Agriculture says that "the number of beef cattle marketed in any 1 year bears a nearly constant ratio to the number of cows and calves remaining on farms" (p. CLIII). After studying this ratio extensively one of the early experts of the Department of Agriculture, Holmes (8, p. 70), wrote:

Meat supply per head of meat animals in stock has increased particularly since 1870, 1880, and 1890. The practice of slaughtering cattle at younger ages, which began less than a score of years ago and which has continuously reduced the average age of cattle slaughtered to the present time, has a certain arithmetical result upon the fraction of meat production by any given number of cattle in stock.

If at the present time 100 cattle in stock produce on the average 24.1 percent of their number annually for slaughter—calves under 1 year not included—computations of the fraction of slaughter under supposed former conditions at the older average age of years also indicate that the fraction of slaughter for cattle, not including calves under 1 year, was perhaps 20 or 21 percent.

Holmes' ratios for 1899 of cattle slaughtered to inventories of cattle 1 year and over are amazingly close to the ratios computed from B. A. E. data. Relating the B. A. E. estimates of slaughter to the B. A. E.-N. B. E. R. computed data on inventories of cattle 1 year and over, the following percentages were obtained: 1900, 23.2; 1901, 24.1; 1902, 23.9; 1903, 24.3; and 1904, 24.1.

The number of head slaughtered was consequently estimated by applying these ratios to the cattle-inventory series. The ratio was assumed to have increased continuously from 20.7 percent in 1867 to 24.1 percent in 1899. An average constant live weight of 950 pounds per head of cattle slaughtered was used to convert slaughter in number of head to slaughter in pounds of live weight, 1869-99. This corresponds to Department of Agriculture estimates for the years around 1899. The age at which cattle were slaughtered declined during this period, but it was assumed that this was compensated for by the better feed utilization due to improvements in breeding. The 1900 Census says: "owing to improvements in breeding \* \* \* 2-year old steers are often produced at a weight equal to that of the older cattle marketed in preceding years." Although there is undoubtedly a margin of error in the assumption of a constant live weight, it is small. Over the entire period 1900-1930 the live weight in any 1 year did not depart more than 5 percent from the average.

An effort was made to check the slaughter estimates derived from

"inventories of cattle 1 year and over on farms" by computing a slaughter series based on consumption of beef per capita. Using B. A. E. slaughter estimates since 1899, farm and nonfarm per capita consumption of beef was computed in pounds. Per capita beef consumption of the farm population was 22.98 pounds in 1899, 32.46 pounds in 1910, 22.59 pounds in 1920, and 11.74 pounds in 1929. The nonfarm population consumed 212.53 pounds, 197.15 pounds, 153.88 pounds, and 118.0 pounds in the corresponding years. Assuming for 1869-98 a per capita consumption of 200 pounds for the nonfarm population and of 20 pounds for the farm population, and basing the computation for census years on estimates of farm and nonfarm population made by the Agricultural Adjustment Administration (28), it was found that the trend of slaughter as indicated by this method of estimating is similar to the trend computed on the basis of inventories. Intercensus year data were obtained from a straight-line interpolation of the percentage of farm population to total population. This check has meaning only insofar as the total movement of slaughter during these three decades is concerned; that is, it corroborates the indication that slaughter increased from about 4 billion to 10 billion pounds.

Only a slaughter series corresponding to inspected slaughter has formerly been available for 1879-99. This was known to include a serious bias arising from the sharp increase in Federal inspection. It apparently included about 42 percent of total slaughter in 1879 as against about 70 percent in 1899. The estimates of federally inspected slaughter (old series) as percentages of the B. A. E.—N. B. E. R. estimates of total slaughter of cattle are as follows:

1879.....	41.6	1886.....	41.1	1893.....	72.9
1880.....	42.9	1887.....	44.3	1894.....	76.0
1881.....	41.8	1888.....	50.3	1895.....	73.4
1882.....	41.9	1889.....	55.6	1896.....	74.9
1883.....	59.9	1890.....	61.8	1897.....	73.9
1884.....	40.3	1891.....	60.7	1898.....	62.5
1885.....	41.0	1892.....	68.8	1899.....	70.2

Gross income from the slaughter of cattle was computed for 1869-98 by multiplying slaughter estimates (in pounds) by the (B. A. E.) adjusted farm price of beef (expressed in cents per pound of live weight).

To income from slaughter the income from exports of live cattle was added. Calendar-year exports of live cattle before 1877 were computed by averaging 2 fiscal years; from 1877 to 1904 calendar-year export figures are those of the Cincinnati Price Current; since 1905, the figures are from the Department of Agriculture. According to data of the Department of Agriculture and of G. K. Holmes, the average weight of exported cattle is 1,250 pounds. Exports of cattle, expressed in pounds of live weight, were multiplied by the B. A. E. adjusted farm price of beef cattle to obtain gross income from exports of live cattle.

Production, farm price, and gross income for calendar years 1869-1937 are shown in figures 35 and 36 and tables 48-50.

NOTE.—Minus sign means decrease from preceding year.

CALVES

Estimates of slaughter of calves also are based on the revised inventory estimates of the United States Department of Agriculture. The method was explained in the description of the cattle-slaughter estimates. According to Department of Agriculture data, 29.2 percent of the calves inventories were slaughtered in 1899. Holmes' estimate (8, p. 71) was 31 percent, and he maintained that "the fraction of calves dropped that go to slaughter has undoubtedly increased, partly because of the increase of dairying and partly because of the increased demand for veal in cities." The estimate of the fraction of calves inventories slaughtered 1869-98 here used assumes that 10 percent of the inventories were slaughtered in 1869 and that this percentage increased gradually to 1898. Owing to the roughness of these estimates, the income estimates can be regarded merely as approximations. Department of Agriculture figures for years about 1899 show live weight per head of 170 pounds; this figure was used to compute slaughter in pounds of live weight. To obtain gross income from the slaughter of calves, 1869-98, the B. A. E-N. B. E. R.

slaughter estimates were multiplied by the (B. A. E.) adjusted farm price of calves (veal). The States included in this price are: Wisconsin and Maryland since 1867; New York and Maine since 1882. The B. A. E. farm price, 1910-14, is 10.4 percent lower than the (B. A. E.) price,

B. A. E. 35574

FIGURE 37.—Calves: Production, farm price, gross income, calendar years 1869-1937.

so the latter was adjusted accordingly. Since 1899 Department of Agriculture data on slaughter of calves were used; B. A. E. price data were applied from 1910 to 1935. Slaughter, farm price, and gross income for calendar years 1869-1937 are shown in figures 37 and 38 and tables 51 and 52.

NOTE.—Minus sign means decrease from preceding year.

## HOGS

Revised slaughter estimates (number of head) and data on live weight per head, recently carried back to 1899 by the Department of Agriculture (24, 1938, p. 304) were used. According to these estimates, slaughter (number of head) averaged 102.2 percent of inventories during 1899-1910. The deviations from the average are slight, corroborating Holmes' statement (8, p. 72) that "with regard to hogs, there has been no perceptible increase in the fraction of slaughter (to inventories) on account of slaughtering at younger ages." For 1869-98 slaughter (number of head) was computed as 102.2 percent of inventories. The inventory data are revised Department of Agriculture estimates.<sup>52</sup>

Starting in 1883, the Cincinnati Price Current published data on gross live weight per head. These data were adjusted for differences (after 1899) in the more inclusive live-weight series of the Department of Agriculture. Before 1883, only net live weight per head was available. Net live weight was converted to gross live weight and adjusted to make the data consistent with the later Department of Agriculture data. The (B. A. E.) calendar-year farm price of hogs (cents per pound of live weight) was applied. Gross income from the slaughter of hogs was estimated by multiplying slaughter (total live weight) by farm

<sup>52</sup> See footnote 50.

prices. Exports of live hogs are insignificant and income from exports is therefore not included in the income data here given.

Changes in inventories (number of head) are based on revised Department of Agriculture figures. A constant live weight of 125

B. A. E 35576

FIGURE 39.—Pork and pork products: Production, farm price, gross income, calendar years 1869-1937.

pounds for total inventories was assumed, derived from the 1920 Census of Agriculture (table 53). Since completion of this Bulletin, better data on live weight of inventories have become available for 1924-33. According to these data, the average live weight appears to have been somewhat higher than that used here.

TABLE 53.—Live weight of hogs, based on 1920 Census figures

Item	Percent of total inventories	Live weight
		Pounds
Pigs under 6 months.....	45	50
Breeding stock.....	20	232
All over 6 months.....	35	158
Weighted average live weight.....		123.2

Slaughter, farm price, and gross income for calendar years 1869–1937 are shown in figures 39 and 40 and tables 54 and 55.

SHEEP AND LAMBS

Slaughter data for sheep and lambs combined are available since 1899 in the form of revised Department of Agriculture estimates (24, 1938, p. 320). Owing to rapid changes in taste, particularly

B. A. E. 35577

FIGURE 41.—Sheep and lambs: Production, farm price, gross income, calendar years 1869-1937.

after about 1890, no constant ratio of slaughter to inventories can be detected. According to B. A. E. slaughter data for 1900, nonfarm consumption per capita amounted to 21.16 pounds (live weight), farm consumption to 1.5 pounds. Many observers believe that consumption of mutton and lamb increased rather constantly before 1900.

Holmes' investigations (8) proved to him that "the fraction of lamb slaughter has undoubtedly increased, beginning a few years preceding 1900, on account of the growing taste for lamb meat." He does not indicate the development of total consumption in the early period. The authors let per capita nonfarm consumption gradually increase from 10 pounds in 1869 to 21.16 pounds in 1900 and kept farm consumption constant at 1.5 pounds per capita. Data on farm and non-farm population are those described in the explanation of cattle slaughter. Since before 1890 consumption was predominantly of sheep, and as sheep and lamb prices differed little during this period, sheep prices were applied for 1869-89. From 1890 on, an arithmetic average of sheep and lamb prices was computed. This price may contain a downward bias, inasmuch as it does not consider the influence of the growing taste for lamb meat. The (B. A. E.) sheep price had to be raised 8.1 percent and the lamb price had to be lowered 2.2 percent, to make this series comparable with the B. A. E. series since 1909. Income from the slaughter of sheep and lambs is calculated by multiplying estimated slaughter by farm price. Exports of live sheep and lambs were insignificant. Changes in inventory value were computed with revised Department of Agriculture figures. The average live weight of inventories was assumed to be 85 pounds per head, based on the 1920 census and observations made by the Department of Agriculture.

Slaughter, farm price, and gross income for calendar years 1869-1937 are shown in figure 41 and tables 56-57.

## INDICES OF FARM PRODUCTION AND PRICES

The method of computation of indices of farm production and of farm prices is briefly explained in the introduction to this bulletin.

Figures 42-57 and tables 58-92 show production and price indices for crop years and, whenever the original data are not presented in tables in the section beginning on page 36, they are presented in tables containing data on "Production entering into gross income." Figures 50 through 57 show the various farm-price indices together with the Bureau of Labor Statistics wholesale price index of all commodities.

The original data are described on pages 33 to 122 in connection with the data on gross income.

TABLE 58.—Indices of farm production: Total farm production, crop years  
[1909-13=100]

Year	Arithmetic index	Harmonic index	Ideal index	Year	Arithmetic index	Harmonic index	Ideal index
1869	35.2	33.4	34.3	1903	91.2	89.3	90.3
