#### ACKNOWLEDGMENTS

I am deeply indebted to F. Van Emden, British Museum (Natural History), London, for comparing specimens with the types of Trapanca merarna (Waik.) and vicina (v. d. W.) and to F. L. Blanc, California Department of Agriculture, Sacramento, who borrowed specimens from several west coast collections specifically for this study. I also express my appreciation to the following individuals and institutions for lending me specimens: Paul II. Arnaud, Jr., California Department of Agriculture, Sacramento; Carl Brandborst, University of Nebraska, Lincoln; R. R. Dreisbach, Midland, Mich.; C. F. Knowlton, Utah State University, Logan; and L. W. Quate, formerly of the University of Nebraska. Lincoln; — Academy of Natural Sciences of Philadelphia; American Museum of Natural History, New York; California Academy of Sciences, San Francisco; California Department of Agriculture, Sacramento; California Insect Survey, Sacramento; University of California, Berkeley; University of California, Davis; University of California, Riverside; Carnegie Museum, Pittsburgh, Pa.; University of Colorado, Boulder: Florida State Plant Board, Gainesville: University of Idaho, Moscow: University of Funsas, Lawrence; Los Angeles County Museum, Los Angeles, Calif.; Museum of Comparative Zoology, Harvard University, Cambridge, Mass.; Naturhistorisches Museum, Vienna, Austria: San Diego Natural History Museum, San Diego, Calif.; San Jose State College, San Jose, Calif.; and Stanford University, Stanford, Calif. The U.S. National Museum was an important source of study material.

## A Revision of the Genus TRUPANEA in America North of Mexico

(Diptera, Tephritidae)

By RICHARD H. FOOTE, entomologist, Entomology Research Division, Agricultural Research Service

The genus Trupanea Guettard is a group of small fruit fly species that have gray pollinose bodies, yellowish heads and legs, and wings with a distinctive starlike pattern. Males and females alike visit the flowers of a large number of plants of the family Compositae, and according to the scant biological literature treating this genus, the larvae inhabit ovaries of these flowers, thereby affecting to an unknown extent the production of seed. Apart from an occasional isolated rearing, no concerted effort has been made to study the biology of any of the species or to evaluate the host specificity. The genus is worldwide in distribution, but because of its apparent lack of economically important species, it has been neglected as a taxonomic study.

The genus Trupanea was erected without any included species by Cuettard (1762). Most authors, under the impression that Guettard first used it prior to 1758, have credited Schrank (1765 or 1756) with the name. However, Schrank in his publication assigned a single species, stellata Fuessly (as radiata Schrank 1795 or 1796), which automatically becomes the type by being the first species published in connection with the genus. The name was emended to Trypanea by Agassiz (1846), Bezzi (1913), and by many American entomological writers. The name Urellia Robineau-Desvoidy (1830) is a subjective synonym, since the first of the two included species, calcitrape R.-D., designated as type by Coquillett (1910), is also a synonym of stellata. The common use of the name Urellia by European and American entomological writers is limited to the years prior to 1914, probably a result of Loew's (1862, 1873) adoption of it for European and American species.

The zoological concept of the genus has changed very little through the years, principally because of the very characteristic wing pattern. The keys to the tephritid genera by Loew (1873), Coquillett (1899). Williston (1908), Phillips (1923), and Curran (1932, 1934) reflect rather accurately the proper niche for this genus in the classification systems in use in those years. Keys to North American species of Trupanea have been published by Adams (1904), Phillips (1923), and Curran (1932). The most recent revision of the genus is by

Malloch (1942).

Because wing characters are so easily seen and almost universally present, they have been used almost to the exclusion of other characters to place the species in conveniently handled groups and to identify

<sup>&</sup>lt;sup>1</sup>The year in italies after the author's name is the key to the reference in Literature Cited, p. 26.

species. However, my past attempts at *Trupanea* identifications have met with only partial success because of considerable variation in the wing characters in some species—a fact not mentioned or insufficiently recognized in the past by authors. This revision incorporates my observations on intraspecific variation and is an attempt to remedy this situation. In addition, the photographs of wings and the recast keys should facilitate more accurate identification of the species.

Some species vary considerably in the presence or absence of an infuscation in the distal end of cell R. Since these species appear in two places in the keys to both males and females, no difficulty from this

variation should be encountered in identifying specimens.

Passing reference to sexual dimorphism in the genus has been made in the literature. The differences between males and females are most obvious in nearly every species in the wing pattern. The male wing tends to have larger hyaline areas, with the dark markings correspondingly reduced, broken, or sometimes completely absent. Trupanea bisetosa, femoralis, imperfecta, jonesi, and radifera differ rather markedly in respect to this type of wing pattern. The wings of both males and females of these species are illustrated at the end of this bulletin. Many other species exhibit similar differences in the development of hyaline areas but to a less extent. The separate keys to females and males have been provided to avoid any difficulty that might arise on account of this dimorphism.

Information on hosts in each species discussion has been taken largely from pin labels and represents only those plants from which the adults were collected. It is not intended to be descriptive of the

larval habitat, except where rearing is specifically indicated.

Urella (sic!) Johnson, 1925, Oceas, Papers Boston Soc. Nat. Hist. 7 (15): 264.
 Trupanca (Trupanca), Benjamin, 1934, U.S. Dept. Agr. Tech. Bal. 401: 52.

Diagnosis.—Head usually predominantly yellow or yellowish gray; anterior oral margin not markedly produced; proboscis not geniculate; two pairs upper fronto-orbitals; three pairs lower fronto-orbitals, anterior pair often shorter and weaker than others, but rarely lacking. Thorax and scutellum densely gray dusted; humerals and supra-alars present; one pair dorsocentrals, closer to suture than to line drawn through supra-alars; one pair scutellars, in addition some setae fringing posterior margin of scutellum. Wing with preapical dark mark

and rays radiating to wing margins from stigma to at least cell 2d M and sometimes to cell  $Cu_1$ ; cell 1st A hardly drawn to point at its junction with vein  $Cu_2+2d$  A; veins r—m and m separated by distance along  $M_{1+2}$  approximately equal to length of vein r—m. Legs yellow, with femora sometimes slightly infuscated; males often with series of fine erect hairs on anterior or anteroventral surface of midfemur. Abdomen densely gray dusted; ovipositor and external male genitalia

shining brown or black.

The characteristic subapical stelle a marking of the wing (see figures), together with the absence of dark markings in the proximal posterior quarter of the wing disk, distinguishes species of Trupanea from those of all other North American tephritid genera except Tephritis. However, the definition of a discontinuity between these two genera poses a problem that is not easily solved. Tephritis pura (Lw.), Tephritis subpura (Johns.), Tephritis stigmatica (Coq.), Tephritis labecula Foote, and Trupanea femoralis form a group that, on the basis of wing pattern alone, connects Trupanea and Tephritis by perfectly intergrading steps. These species in the order named show progressively noticeable development of dark markings in the posterior proximal quarter of the wing disk. Trupanea femoralis (figs. 2 and 3) most closely resembles the Trupanea-like end of the intergrade with the lowest degree of such development, and Tephritis pura the other, with a relatively darkened field characteristic of most of the Tephritis species. The separation of the two genera on the basis of wing pattern alone then is not practicable.

Euarestoides and a part of the genus Euaresta have been relegated to the status of subgenera in the genus Trupanea by Benjamin (1934). It is evident that Euarestoides (Foote 1958) has close affinities with Trupanea as defined herein, but we know little about the Neotropical species assignable to it. The genus Euaresta as defined by Quisenberry (1950) is a group of closely related species considerably removed from Trupanea, and the placement of some of its species in Trupanea would no longer reflect its true phylogenetic composition. Moreover, the relationship to Trupanea of the species in Neotephritis and Paroxyna, genera not mentioned by Benjamin in this connection, should be more fully evaluated before Benjamin's views are adopted.

According to most European entomological authors and Quisenberry (1951), this impasse is resolved by restricting the genus Trapanca to those stellate-winged species having only one pair of scutellars and three pairs of lower fronto-orbitals. I agree with Quisenberry that the tendency of wing patterns to be Trapanca-like in the species placed in Tephritis by this concept (e.g., stigmatica and labecula) is of only specific significance. Tephritis stigmatica, commonly regarded in the past as a Trapanca species with two pairs of scutellars, has already been included by Quisenberry (1951) in his revision of Nearetic Tephritis species, as have Tephritis pura and submara.

On the basis of wing pattern, the species fall into the following

groups:

A. Dark my from stigma to cross vein as wide or nearly as wide as length of stigma—conjuncta, femoralis, nigricornis, and bisetosa

- AA. This dark ray much narrower than length of stigma
  - B. Two dark rays through cell 1st M<sub>2</sub>—dacetoptera, arizonensis, wheeleri, mevarna, texana, and ageratae
  - BB. Only one dark ray through cell 1st M2
    - C. Hyaline spot at base of cell R<sub>5</sub> indistinct—actinobolic, californica, and vicina
    - CC. Hyaline spot at base of cell R<sub>s</sub> wide and extending completely across cell—jonesi, pseudovicina, radifera, eclipta, and imperfecta

In this outline no attempt was made to establish primitive or advanced conditions of the groups relative to one another. The major divisions are essentially the same as those used in the keys and were conceived primarily for convenience in identifying species.

#### KEY TO FEMALES 2

1. Unbroken dark-brown area in distal anterior quarter of wing disk; proximal half of wing light brownconjuncta (Adams) (p. 8) Wing with preapical dark area in distal third or half of cell R <sub>2</sub> and basal half of cell R <sub>3</sub> , with narrow dark rays diverging from it to margins 2
2. Vein r-m connected to stigma by dark ray as wide or nearly as wide as length of stigma
3. Two dark rays partially or entirely across cell 1st M <sub>2</sub> : vein Cu <sub>2</sub> +2d A infuscated on most of its length
<ol> <li>Two dark rays through cell 1st M<sub>2</sub>, proximal one sometimes broken in posterior half of cell and not attaining vein M<sub>1</sub>+Cm<sub>1</sub> or broken in center of cell.</li> <li>One dark ray through cell 1st M<sub>2</sub>: in addition, sometimes a spot near middle of that cell and a dark spot in line with it on vein M<sub>2</sub>+Cm<sub>1</sub> or with other markings within cell proximal to distal ray.</li> </ol>
5. Distal ray through cell 1st M <sub>2</sub> continuing to hind margin of wing; if broken in cell Cu <sub>0</sub> , its continuation always marked by a dark marginal spot
6. Proximal ray ending at middle of cell 1st M <sub>2</sub> ; never with a dark spot in line with it on vein M <sub>3</sub> + Cu <sub>1</sub>
7. Distance along vein Ma+Cu <sub>t</sub> between proximal and distal rays in cell—1st M <sub>2</sub> greater than distance between distal ray and vein m; dark mark on vein M <sub>4</sub> +Cu <sub>t</sub> at middle of that veinarizonensis Mail. (p. 12) Distance along vein M <sub>5</sub> +Cu <sub>t</sub> between proximal and distal rays equal to or less than distance between distal ray and vei; m; dark mark on vein M <sub>2</sub> +Cu <sub>t</sub> distinctly apical of middlemaculigera, n. sp. (p. 13)
8. Elongate dark streak from base to middle, or beyond, of vein M <sub>4</sub> +Cu <sub>4</sub> , wheeleri Curr. (part) (p. 14) Base of vein M <sub>4</sub> +Cu <sub>4</sub> entirely without infuscation, but a dark spot may be
present near middle of that vein9

<sup>2</sup> Female of ageratac Benj. not known,

9.	Marginal light spot at apex of vein R <sub>2-2</sub> centered in surrounding dark area: hyaline spot immediately distad of stigma rather pointed apically	
10.	Hyaline spot immediately anterior to vein m quadrate and attaining vein $R_{\text{2-$\pi$}}$ along most of its widthimperfecta (Coq.) (p. Hyaline spot immediately anterior to vein m rounded anteriorly and rarely exceeding posterior two-thirds of cell $R_{\text{2}}$	18) 11
11.	Distal end of cell R completely hyaline, but occasionally a very narrow band of infuscation bordering vein r-m	12 18
12.	Dark ray from stigma to vein r-m distinctly broken either in cell $R_1$ or cell $R_2$ .  Dark ray from stigma to vein r-m complete in cells $R_1$ and $R_2$ , although it may be broken within stigma.	13 14
13.	Dark ray from stigma to vein r-m broken in cell R, and complete in cell R,———————————————————————————————————	Ĺ
14.	Infuscation at center of vein $M_2 + Cu_1$ elongate, at least three times as long as wide	·
15.	Marginal light spot at apex of vein R <sub>2-3</sub> very close to distal margin of dark area surrounding it	
16.	Proximal light spot in cell $R_2$ distinct, broadly based on vein $M_{1-2}$ , and extending about two-thirds of way across cell $R_3$ .  **pseudovicina Her. (p. Proximal light spot in cell $R_4$ lacking, indistinct, or extending clear across	
17.		_
18.	Apex of cell R with dark even infuscation similar to that in base of cell R <sub>7</sub> ; proximal border sharply delimitedvicina (v. d. W.) (p. Apex of cell R with infuscation either in distinct spot surrounded at least in part distally by a lighter or hyaline area, or broad and lightly arcolate; proximal border never sharply delimited	25} 19
19.	Vein M <sub>2</sub> +Cu, with elongated infuscated streak from its base to its mid- point or slightly pastwheeleri Curr. (part) (p. Infuscation on vein M <sub>2</sub> +Cu <sub>1</sub> in form of spot or entirely lacking	14) 20
20.	Brownish species with hyaline area immediately distad of stigma more or less acute apically	15) 21
21.	Infuscation in apex of cell R with distinct margins.  signala, n. sp. (part) (p.	
22.	Infuscation in apex of cell R indistinctly margined  Marginal hyaline spot at apex of vein R <sub>243</sub> separated from next distal hyaline area by a dark ray about as wide as that covering vein m; Western United States  ———————————————————————————————————	

#### KEY TO MALES

1.	An unbroken dark-brown area in distal anterior quarter of wing disk; proximal half of wing light brown	
2,	Dark ray connecting stigma with vein r-m as wide or nearly as wide as length of stigma	3
3,	Two dark rays partially or entirely across cell 1st M <sub>2</sub> ; vein Cu <sub>2</sub> +2d A infuscated on most of its length	i. 81
4.	Third antennal segment dark brown to black; apical Y-shaped mark incomplete; vein M <sub>2</sub> +Cu <sub>1</sub> with dark spot at center.  **nigricornis** (Coq.) (1)	
	Third antennal segment yellow, about same color as second; apical Y-shaped mark complete; vein $M_3$ + $Cu_4$ completely devoid of markings————————————————————————————————————	
<b>5</b> .	Two dark rays through cell 1st $M_2$ , the proximal one sometimes broken in posterior half of that cell and not attaining vein $M_1 + Cu_1 - Cu_2 - Cu_3 - Cu_4 - Cu_3 - Cu_4 - Cu_5 - C$	C

20.	Apex of cell R with dark even infuscation similar to that in base of cell R, its proximal border sharply delimitedvicina (y, d, W,) (p. 2). Apex of cell R with infuscation either in a distinct spot surrounded at least in part by a lighter or hyaline area, or broad and lightly areolate, the proximal border never sharply delimited	5) 21
21.	Vein M <sub>3</sub> +Cu <sub>1</sub> with elongate infuscated streak from its base to its midpoint or slightly pastwheeleri Curr. (part) (p. 1. Infuscation on vein M <sub>2</sub> +Cu <sub>1</sub> in form of a spot or entirely lacking	4) 22
22.	Brownish species with hyaline area at apex of stigma more or less acute apicallymevarna (Walk.) (part) (p. 13) Grayish species with hyaline area at apex of stigma rounded broadly posteriorly or ending broadly along vein R <sub>1-5</sub>	5) 23
23.	Infuscation in apex of cell R with distinct margin.  signata, n. sp. (part) (p. 2)	91
	Infuscation in apex of cell R indistinctly margined	24
24,	Marginal hyaline spot at apex of vein R <sub>2-7</sub> separated from next distal hyaline area by a dark ray about as wide as that covering vein m; Western United States	-

#### DESCRIPTIONS OF SPECIES

#### Trupanea conjuncta (Adams)

(Fig. 1)

Urcilia conjuncta Adams, 1904, Kans. Univ. Sci. Bul. 2: 450, 451 (type loc. Bill Williams Fork, Ariz., holotype 9, descr.).—Snow, 1904, ibid. 2: 345 (in list Dipt. Ariz.).

Trypunca conjuncta. Malloch, 1942, U.S. Natl. Mus. Proc. 92: 4, 12, fig. 1, n (short descr., fig. wing ?).

Previously recorded distribution.—Bill Williams Fork and White Mountains, Ariz.

Material examined.—Holotype 9 with the following labels: "Bill Williams Fouls, Axis 2 and "Tains 2"

Williams Fork, Ariz." and "Type."
ARIZONA: 1 &, White Mountains, 7.VII.33. Parker Lot 106.
CALIFORNIA: 1 &, Andreas Canyon near Palm Springs, 1.III.51.
on Encelia farinosa, Timberlake.

Location of type.—University of Kansas, Lawrence.

Discussion.—This species will not be mistaken for any other North American Trupanea on account of its unusual wing pattern (fig. 1), which consists of an unbroken dark-brown area occupying the anterior distal quarter of the disk. This dark area is separated from the light-brown area in the anterior proximal half of the wing by several hyaline spots and by a very narrow dark ray from the stigma to near vein r-m (in this respect similar to Euurestoides ubstersa (Lw.)). The heads of both sexes are subquadrate from the lateral aspect, the forefemora of the male are distinctly dilated, and the ovipositor sheath is approximately 1½ times as long as the two preceding abdominal tergites.

#### Trupanea femoralis (Thomson)

(Figs. 2 and 3)

Trypctu femoralis Thomson, 1868, Fregatten Eugenies Resa 6 (2); 582 (type loc. Calif., holotype ', deser.).—Loew, 1873, Smithsu, Inst. Misc. Collect. 11 (256); 342 (Thomson's orig. deser. reprinted).

Urcilia femoralis, Loew, 1873. ibid. 11 (256): 336, 339 (transfers to Urcilia).—Osten Sacken, 1878, ibid. 16 (270): 195 (Calif.).—Adams, 1904. Kans. Univ. Sci. Bul. 2: 450 (in key N.A. spp.).—Aldrich, 1905. Smithsu. Inst. Misc. Collect. 46 (1444): 613 (in list N.A. spp., refs., distr.).

Urcilia occidentalis Adams, 1904, Kans. Univ. Sci. Bul. 2: 450 (in key N.A. spp., descr.). NEW SYNONYMY.

Trypanca occidentatis, Malloch, 1942, U.S. Natl. Mas. Proc. 92: 17 (short descr.). Trypanca femoratis, Malloch, 1942, ibid. 92: 3, 10, fig. 1, i (short descr. £, fig. wing).

Previously recorded distribution.—California.

Material examined.—Male holotype with the following labels: "California," "Kinb.," "Typus," "Trypeta femoralis Thoms.," and "402-57." One 3. two 22, various localities in California (cotype series of occidentalis Adams—see below for lectotype designation).

CALIFORNIA: 42 & 8, 61 9 9, 57 localities throughout State, January through December. Among these localities the larvae have been reared to adults from the flowers of Aplapappus renetus. Aster spinosus, and Heterotheca grandiflora. Adults have been collected

from the following plants: Amaranthus graccizans, Aplopappus linearifolius, Atriplex polycarpu, A. semibaccata, Bussia hyssopifolia. Centromodia pungens, Erodium cicutarium, Franseria acanthocarpa, Hemizonia sp., Layia platyglossa, and Monolopia major. They have also been captured in traps baited for the walnut husk fly (Rhugoletis completa Cress.) and the melon fly (Dacus cucurbitae Coq.).

Location of types.—()f femoralis—Naturhistorisches Museum, Vienna; of lectotype of occidentalis—University of Kansas, Lawrence.

**Discussion.**—The type series of *occidentalis* consists of one male and two females from California and one male from Wyoming. The California female with the labels "L. S. Jr. U., Lot 61, sub.," "Type," and in red, "cotype, Urellia occidentalis Adams" is hereby selected as the lectotype of *occidentalis*. The three California specimens fall without question within the range of variation of the California material of *femoralis* examined in this study, whereas the Wyoming male is obviously *Tephritis labecula* (Foote 1959).

The wing of the male holotype differs from that of the Desert Springs, Calif., specimen shown in figure 2 in possessing only a very small remnant of the apical Y-shaped mark, a slightly larger hyaline spot at the apex of vein R<sub>2.3</sub>, and a more distinct hyaline area on each side of vein r-m. In addition, the dark rays in cell 1st M<sub>2</sub> are complete from vein M<sub>1,2</sub> to a point about halfway across the cell, where they disappear. Considerable variation in the pattern in cell 1st M<sub>2</sub> was observed in the males studied, but in every specimen at least the presence of both rays was indicated, and the dark ray connecting the subapical dark area to the stigma leaves the apical half to two-thirds of the stigma almost completely hyaline along the costa. The male possesses a patch of long, dark, creet setae on the middle half of the anterior surface of the midfemur. These are usually arranged in three irregular rows; the most ventral is the longest and stoutest.

The wing of the female (fig. 3) is similar to that of the male, but the apical Y-shaped mark is always present, the hyaline areas on each side of vein r-m are reduced, and the two rays through cell 1st  $M_2$  are nearly always complete. The heads of both sexes are higher than long from the lateral aspect. The ovipositor sheath is about as long as the three preceding abdominal tergites, and its basal half is covered with short, stout, yellow setae.

The reader is referred to the discussion (p. 3) of the generic limits of *Trapanea* regarding the separation of *femoralis* from the species closely related to it, and to an article by Foote (1959) for a description of *Tephritis laberala*, the wing pattern of which is very similar to that of *femoralis*.

#### Trupanea nigricornis (Coquillett)

(Fig. 4)

Urchin nigricornis Coquillett, 1899, N.Y. Enr. Soc. Jour. 7: 266 (type loc. Colo., holotype ?, descr.), "Snow, 1904, Kans. Univ. Sci. Bul. 2: 345 (in list Dipf. Ariz.).—Adams, 1904. Ibid. 2: 450 (in key N.A. spp.).—Addrich, 1905, Smithsn. Inst. Misc. Collect. 46 (1444): 614 (in list N.A. spp., distr.).

Trypanca nigricovnis, Curran, 1932, Amer. Mus. Novitates No. 556: 6 (in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 3, 5, 10, fig. 1, f (short descr., fig. wing  $\,^{\circ}$ ).

Previously recorded distribution.—Arizona and Colorado.

Material examined.—Males only. Male holotype with the following labels: "Colo., 1684," "Collection Coquillett," "Type No. 4411,

U.S.N.M.," and "Trypanea nigricornis Coq."

ARIZONA: 8, Atacosa Mountain, Bill Williams Fork, Boulder Dam, Chiricahua Mountains, 15 miles west of Gila Bend, Lee Siding (Pedregosa Mountains), Tusayan, 6.VI to 8.AII. (CALIFORNIA: 59, 31 localities throughout State, January through December. COLORADO: 3, 7 miles south of Glade Park, Meeker, 22.VI to 21.VII. IDAHO: 9, Albion, Burleigh, Castleford, Conant, Hollister (Mountain Home), Murtaugh (Oakley), 10.VI to 2.IX. NEVADA: 8, Austin, Glendale, Reno, Wells, 6.V to 23.X. NEW MEXICO: 7, Fort Wingate, Nogal, Santa Rosa, 23.VI to 1.VIII. OREGON: 1, Harney County, 29.VI.53. UTAH: 63, 19 localities throughout State, May through September. WYOMING: 3, Green River, Yellowstone National Park, 2.VII to 12.VIII.

Females of "nigricornis-bisetosa" have been taken in Arizona, California, Colorado, Idaho, Nevada, New Mexico, Utah, and

Wyoming.

Adults have been collected from Artemisia tridentata. Atriplew rosea, Baccharis pilularis. Beta vulgaris, Chrysothamnus paniculatus. C. speciosus. Croton longipes, Encelia farinosa, Franscria sp., Melilotus sp., Pluchea sericea, Salsola kali var. tenuifolia, Senecio douglasii, Stanleya sp., and Taraxacum sp.

Location of type.—U.S. National Museum, Washington, D.C.

**Discussion.**—Males of this species may be recognized easily by the very dark-yellow to black third antennal segment: the distinctly quadrate nature of the infuscated spot posterior to the stigma, in which vein  $R_{4-5}$  is infuscated to a point directly below the major bend of the subcosta; the presence of a distinct dark spot in the center of vein  $M_3+Cu_1$ : and the absence of the posterior arm of the apical Y-shaped mark. The wing of the Nevada specimen shown in figure 4 differs from that of the Colorado type only by the slightly smaller hyaline spot at the anterior end of vein  $R_{2+3}$ . Differences from bisetosa, its absence of the unique that species.

its closest relative, are discussed under that species.

Although males of nigricornis and bisetosa can always be separated according to the characters given above and under bisetosa. I have failed to discover any satisfactory means for associating females with the males of either of these species. A large series of females from California and other localities in the Southwestern United States were examined. Every possible intergrade between black and yellow was found in the third antennal segment, the character used by Malloch (1942) in his key to females. Furthermore, each of the other characters useful in distinguishing males of nigricornis from those of bisetosa breaks down; consequently, a separation of the large series into two distinct groups, each of which might be assignable to one or the other species on the basis of more than a single character, has been unsuccessful repeatedly. Variations in the female wing pattern of bisetosa are discussed under that species.

#### Trupanea bisetosa (Coquillett)

(Figs. 5 and 6)

Urcllia bisotosa Coquillett, 1899, N.Y. Ent. Soc. Jour. 7: 266 (type loc. Las Cruces, N. Mex., brief descr.).—Snow, 1904, Kans. Univ. Sci. Bul. 2: 345 (in list Dipt. Ariz.).—Adams, 1904, ibid. 2: 450 (in key N.A. spp.).—Aldrich, 1905, Smithsn. Inst. Misc. Collect. 46 (1444): 613 (in list N.A. spp., distr.).

Trypanea bisetosa, Curran, 1932, Amer. Mus. Novitates No. 556: 6 (in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 4, 5, 12, fig. 1, o, p (brief

descr., fig. wings of and ?).

Previously recorded distribution.—Arizona, New Mexico, and Utah. Some of these records may apply to nigricornis, since identifications may have been based on females alone.

Material examined.—Female holotype with the following labels: "Las Cruces, N.M.," "Ckll. 4846, on Bigelovia," "U.S.N.M. Acc.

30623," "Type No. 4410, U.S.N.M.," and "Urellia bisetosa Coq."

The following localities are based on males only. ARIZONA: 1, 5 miles east of Kingman, 1.VII.52. CALIFORNIA: 36, 33 localities throughout State, February through December. COLORADO: 1, Glenwood Springs, 5.VIII.20. IDAHO: 1, Hammett, 12.VIII.40. NEVADA: 1, Fallon, 12.VIII.40. NEW MEXICO: 1, Bernalillo County, VI.96. TEXAS: 1, El Paso, 8.VII.48. UTAH: 1, Learnington, 7.VII.54. WYOMING: 1, Teton, 19.VII.36.

Adults have been collected from Baccharis sergiloides, Croton

californicus, Encelia californica, E. farinosa, Helianthus annuus, H.

sp., Melilotus sp., and Senecio sp.

Females of "nigricornis-bisetosa" have been taken in Arizona, California, Colorado, Idaho, Nevada, New Mexico, Utah, and Wyoming.

Location of type.—U.S. National Museum.

Discussion.—The holotype of bisetosa is taken to be a female from Las Cruces, N. Mex., labeled as stated above by Coquillett, although he

failed to publish a designation in his original description.

As a consequence of my inability to definitely associate females with males known to be nigricornis, I have illustrated the wing of a Santa Paula, Calif., female. The pattern of the holotype wing differs from that of this specimen only in having the dark ray through cell 1st M<sub>2</sub> complete to vein M<sub>3</sub>+Cu<sub>1</sub> and vein R<sub>5</sub> infuscated somewhat more

proximally.

The wing of the *bisetosa* male (fig. 6) differs significantly from that of the nigricornis male, because the infuscated spot posterior to the stigma is somewhat slanted toward vein m, so that the infuscation of vein  $R_{4+5}$  begins well distad of the major bend in the subcosta. There is no trace of a dark spot in the center of vein M3+Cu4, and the apical Y-shaped marking is uninterrupted. In addition, the distance along vein M1+2 between veins r-m and m is about equal to the length of vein r-m in bisetosa and distinctly longer in nigricornis.

#### Trupanea dacetoptera Phillips

(Fig. 7)

Trypanea dacetoptera Phillips, 1923, N.Y. Ent. Soc. Jour. 31: 148, fig. 59 (type loc. Karner, N.Y., holotype 9, descr., fig. wing).—Johnson. 1925, Occas. Papers Boston Soc. Nat. Hist. 7 (15): 265 (in list Dipt. N. Eng.).—Carran, 1932, Amer. Mus. Novitates No. 556: 6 (in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 4, 5, 14, fig. 1, t (short descr., fig. wing 9). Trupanea (Trupanea) dacctoptera, Benjamin, 1934, U.S. Dept. Agr. Tech. Bul.

401: 54, fig. 38, A-G (descr., hosts, distr., fig. wings of and 9).

Previously recorded distribution.—Connecticut, Florida, Maine, Massachusetts, New Hampshire, New York, and Rhode Island.

Material examined.—DISTRICT OF COLUMBIA: 2 & &, Rock Creek Park, 15.VI.13. FLORIDA: 21 & &, 12 & &, Orlando, 29.IX to 23.XI, 1929 and 1930. MARYLAND: 1 &, Chesapeake Beach, 2.VII.24. MICHIGAN: 2 & &, Cheboygan and Livingston Counties, 6.VI to 20.VI. NEW HAMPSHIRE: 1 &, White Mountains. NEW JERSEY: 1 &, 2 & &, Cape May, Morgan, 31.VII to 11.IX. NEW YORK: 1 &, 1 &, Babylon (L.I.), Ithaca, 24.V. NORTH CAROLINA: 1 &, Lake Toxaway. PENNSYLVANIA: 3 & &, Germantown, Hazelton, Pleasanton, 5.VII to 11.VIII. SOUTH CAROLINA: 1 &, Clemson, S.VIII.51. VIRGINIA: 1 &, 1 &, Difficult Run, 14.IX.13. WEST VIRGINIA: 1 &, French Creek (Upshur County), 19 to 24.IX.38.

Larvae have been reared in Florida from Chrysopsis microcephala and Gnuphalium obtusifolium.

Location of type.—Cornell University, Ithaca.

**Discussion.**—The combination of the following characters in the female distinguishes ducetoptera from all other Trupanea species having the distal ray through cell 1st M2 to the hind margin: Ray from stigma to vein r-m complete or nearly so; marginal hyaline spot at apex of vein R<sub>2-3</sub> narrower than dark area just distal to it; distal dark ray through cell 1st M2, if broken posterior to vein M2+Cu1, with definite dark spot marking its termination on hind margin of wing: proximal ray ending in middle of cell 1st M2; and area in cell R from vein r-m to point proximad of apex of vein R, broadly infuscated. In many females distal ray in cell 1st M2 and that covering vein m are fused; hyaline spot is left just below their origins. Proximal ray through cell 1st  $M_2$  never attains vein  $M_3$ +Cu<sub>1</sub> and often bends distinctly proximad in that cell, in distinct contrast to that ray in urizonensis, in which it continues over vein M3+Cu1, or if it is broken in cell 1st M2, it is continued beyond vein M3+Cu1. T. dacetoptera differs from arizonensis in its larger size, broad infuscation in apex of cell R, and absence in cell Cu, of continuation of proximal dark ray through cell 1st M2, and other differences discussed under arizonensis.

The wing pattern in males closely resembles that in figure 7. The principal differences are the variable position of the hyaline spot at the apex of vein  $R_{2+3}$  and the variable extent of infuscation in the apex

of cell R.

A study of the type of polyclona Lw. from Cuba in the Museum of Comparative Zoology, Harvard University, shows that it is certainly congeneric but resembles in no way any North American Trupanea.

#### Trupanea arizonensis Malloch

(Fig. 8)

Trypanea arizonensis Mailoch, 1942, U.S. Natl. Mns. Proc. 92: 5, 15, fig. 1, v (type loc. Tucson, Ariz., holotype ?, descr., fig. wing).

Previously recorded distribution.—Tucson, Ariz.

Material examined.—Holotype 2, the topmost specimen on one pin with four females, each on a point, and with the following labels: "Tucson, Ariz., 25.II.34, Bryant 429" and "U.S.N.M. Type, top speci-

men." Paratypes, six 9 %, same data as type, three on a pin with the holotype and three on another pin with the label "Paratypes."

ARIZONA: 2 99, 9 miles west of Onion Saddle (Chiricahua Mountains), Pinery Canyon, 12.VI to 10.IX. CALIFORNIA: 2 35, 19, Hunter's Spring (Riverside County), Redondo, 10.V to 18.VII. TEXAS: 1 9, Brownsville, 4.II.45.

Location of type.—U.S. National Museum.

**Discussion.**—T. arizonensis resembles maculigera, n. sp., in having the proximal dark ray through cell 1st  $M_2$  continuing to at least vein  $M_3+(u_1)$  and often beyond, and it is similar to ducetoptera in the position of the marginal hyaline spot at the apex of vein  $R_{2+3}$ . However, arizonensis readily can be distinguished from both these species by the angle at which the proximal dark ray extends through cell 1st  $M_2$ , resulting in a greater distance along vein  $M_2+Ca_1$  between the proximal and distal rays than between the distal ray and that covering vein m. Males of this species are like the females in every important wing-pattern character.

#### Trupanea maculigera, new species

(Fig. 9)

Head.—Slightly higher than long from lateral aspect: width of cheek directly below eye about one-fifth eye height; apex of third antennal segment nearly attaining oral margin; width of froms at vertex equal to length of from from vertex to lumile and 1½ times

as wide as one eye.

Thorax.—Mesonotum light-gray pollinose, with number of slender, whitish setae covering surface, other bristles black; humerus, notopleuron, and upper border of mesopleuron yellow pollinose; pleural sclerites gray pollinose as mesonotum; scutellum concolorous with mesonotum, single pair of scutellars black. Legs entirely yellow; midfemur of male with three to five erect, anterior, yellowish bristles. Wing (fig. 9) with preapical dark area similar to that of most other species of genus; apical Y-shaped mark present and complete in both sexes; marginal hyaline spot at apex of vein R2-3 about same width as infuscated marginal area immediately apicad; dark ray connecting stigma to vein r-m distinctly narrower than length of stigma, especially in that cell, broadening somewhat posterior to stigma and fading to yellow brown along proximal edge of ray; cell R broadly infuscated apically, this dark area fading to yellow brown proximally; hyaline spot immediately unterior to vein m small, rounded, occupying posterior third of cell R, at that point; distal infuscated ray through cell 1st  $M_2$  continuing over vein  $M_3 + Cu_1$  to margin, unbroken in type series, sometimes joined narrowly to dark ray over vein m, thus a small hyaline spot left near their bases; proximal dark ray in cell 1st M2 extending unbroken halfway into cell, at which point it is joined by short dark spot lying parallel with long axis of cell 1st M2; this proximal ray continuing unbroken in females across vein M3+Cu1 and extending well into cell Cu1: in males ray across posterior half of cell 1st M2 often broken; both sexes with distinct dark area along vein M3+Cu, proximal of proximal ray and joining it on vein, this dark area of vein Ma+Cu, from three to six times as long as wide and sometimes extending almost to base of vein; proximal third of wing hyaline.

**Abdomen.**—Color, pollinosity, and setation as on mesotherax and scutellum; ovipositor sheath shining black, about as long as last two abdominal tergites, basal third to half covered with yellowish-white hairs; external male genitalia shining black.

Types and material examined.—Holotype: 2, Otay, San Ysidro (Calif.), 4.XI.50, reared from galls in *Gnaphalium* sp., San Ysidro No. 1335. U.S. National Museum Type No. 64291. Paratypes: 1 & , 4 2 2, same data as holotype (U.S. National Museum): 1 2, Warner Springs (San Diego County, Calif.), 30.VIII.51 (lost).

Location of type.—U.S. National Museum.

**Discussion.**—The species is distinctive in having two infuscated rays through cell 1st  $M_2$ , the proximal to beyond vein  $M_4+Cu_1$  and with transverse dark spots attached to it in the middle of cell 1st  $M_2$  and along vein  $M_4+Cu_1$ , the distal extending to the wing margin. The species closely resembles ducetoptera, from which it may be separated by the position of the hyaline spot at the apex of vein  $R_{2+3}$ , the proximal dark ray through cell 1st  $M_2$  crossing vein  $M_3+Cu_1$ , and by the presence of outstanding anterior midfemoral bristles in the male.

This species has been reared from the same host as that reported by Benjamin (1934) in Florida for dacetoptera. In spite of all similarities, I consider this to be a distinct species until intergrades have been discovered in the very wide geographical area separating maculigera and dacetoptera.

#### Trupanea ageratae Benjamin

(Fig. 10)

Trupanca (Trupanca) ageratae Benjamin, 1934, U.S. Dept. Agr. Tech. Bul. 401; 56, fig. 40 (type loc. No Name Key, Fla., holotype 7, descr., fig. wing), Trypanca ageratae, Malloch, 1942, U.S. Natl. Mus. Proc. 92; 3, 8, fig. 1, c (fig. wing 9).

Previously recorded distribution.—Florida.

Material examined.—Male holotype with the following labels: "Ferry Landing, No Name Key, Fla., 23.X1.30." "Bred from Ageratum littorale, D. J. Nicholson," "U.S.N.M. Type No. 54386," and Trupanea ageratae, type." This is the only specimen seen in this study.

Location of type.—U.S. National Museum,

**Discussion.**—The relationships of the holotype to dacetoptera and mevarna have been discussed adequately by Benjamin (1934). In his treatment no mention has been made of texana, which ageratae markedly resembles, or is any reference made to this relationship by Malloch (1943). The two species may be separated by their geographical distribution and by the characters given in the key. Further discussion of ageratae will be found under texana.

#### Trupanea wheeleri Curran

(Fig. 11)

Trypanca wheeleri Curran, 1932, Amer. Mus. Novitates No. 556; 6, 7, fig. 1 (type loc. San Diego, Calif., holotype 4, descr., fig. wing, in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92; 6, 17 (brief descr.).

Previously recorded distribution.—San Diego, Calif.

Material examined.—Holotype 2 with the following labels: "San Diego, Calif., II.23.97" and "Trypanea wheeleri Curran & type."

Two female paratypes, same data.

ARIZONA: 1 9, Chiricahua Mountains, 7.VIII.41. CALIFOR-NIA: 39 & &, 103 & 2, 79 localities throughout State, every month of the year. Collected from species of Aster, Baccharis, Chrysothamnus, Oirsium, Coreopsis, Encelia, Gutierrezia, and from Lepidospartum squamatum. It has been reared from flowers of Aplopappus venetus and Aster spinosus and has been caught in traps baited for the melon fly in a wide variety of plants in this State. NEW MEXICO: 3 9 9, Alamagordo, 30.IV to 9.V.02. UTAH: 1 8, 1 9, Logan Canyon, Promontory, 26.V to 13.IX.

Location of type.—American Museum of Natural History.

Discussion .- The elongate streak from the base to past the middle of vein M3+Cu1 distinguishes this species from all others with the apex of cell R definitely infuscated and from all North American species except femoralis, which has a broad dark ray from the stigma to vein r-m. In the long series available to me there is considerable variation in the completeness of the proximal dark ray across cell Figure 11 shows one extreme, in which this ray is entirely absent, whereas other specimens have the ray complete, and all intermediates are present. Very often the two ends of the ray are discernible as outcroppings of the dark area around vein r-m and anterior extensions of the distal end of the elongate marking on vein M3+Cu1. Males are in all respects similar in wing pattern to females.

The wing of the type differs from that illustrated in having the anterior ray of the apical Y-shaped mark missing and more extensive markings near the apex of cell R. The proximal ray through cell 1st M<sub>2</sub> is complete in one wing of the holotype but almost completely missing in the other. In both paratypes the apical Y-shaped mark is complete, and in one there is a bridge between the distal ray

through cell 1st M2 and the ray covering vein m.

#### Trupanea mevarna (Walker)

(Fig. 12)

Trypela mevarna Walker, 1849, List Dipt. Brit. Mus. 4: 1023 (type loc. Fla., holotoype 2).—Osten Sacken, 1858, Smithsn. Inst. Misc. Collect. 3 (1): 79 (Fb.).—Loew, 1862, ibid. 6 (1): 59, 61, 96 (in list N.A. sop.).

Trypanca mevarna, Phillips, 1923, ibid. 31: 148 (=daphne Wied.).—Johnson, 1925. Occas. Papers Boston Soc. Nat. Hist. 7 (15): 264 (in list Dipt. N. Eng., solaris Lw. a synonym).—Malloch. 1942. U.S. Natl. Mus. Proc. 92: 4, 6, 14, fig. 1, s (deser., fig. wing ₹).

Trupanca (Trupanca) merarna, Benjamin, 1934, U.S. Dept. Agr. Tech. Bul. 401:

54, fig. 39, A-L (descr., discuss., hosts, fig. wings 6 and 9, larva).

Previously recorded distribution.—Of mevarna—Arizona, California, Florida, Massachusetts, New Jersey, Oregon, Rhode Island, and Texas; of solaris-Guerrero (Mex.), "prob." California, Georgia, Kansas, and Oregon. No specimens recognized as merarna were found in this study from localities other than the Eastern States. Any references indicating merurna and solaris occur in western localities are without doubt based on misidentifications.

Material examined.—Holotype 9 with the following labels: "Georgia," "Loew Colln.," "solaris Loew," and "Type 13223."

ALABAMA: 1 2, Birmingham, 8-9, VIII.16, FLORIDA: 11 & &, 30 9 9 . Benson Springs, Bonifay, Gainesville, I mile west of Malabar, Martin County, Orlando, Ponce de Leon, 6 miles northwest of Tavares, 11.V to 5.XI. Reared from the following species of Chrysopsis in this State—graminifolia, graminifolia var. lutifolia, microcephala, and oligantha. GEORGIA: 1 8, 3 9 9, St. Simon's Island, southern Georgia, 22.V to 12.VI. NEW JERSEY: 1 & Lucaston, 11.IX.10. NORTH CAROLINA: 1 8, collection of Coquillett. SOUTH CAROLINA: 1 &, 1 &, Clemson, Ellorce, 14.VI to 18.VIII.

Location of types.—Of mevarna—British Museum (Natural History); of solaris-Museum of Comparative Zoology, Harvard Uni-

versity.

Discussion.—Several writers have considered solaris Loew a synonym of merurna. After a careful examination of the type of solaris Loew at Harvard University, I have no doubt that it is conspecific with mevarua Walker. Phillips' (1923) unexplained synonymy of mevarna and solaris with dupline (Wied.) is in my opinion incorrect. Although I have not seen the type of dupline (from Montevideo, Urugnay), I agree with Benjamin (1934) that there are few, if any, species of Trupanea described from the Neotropical region that extend into the Nearctic. In spite of the marked similarity in wing pattern between occasional North and South American species, in my experience always other unrecorded differences of a specific level can be found upon a close comparison of specimens.

The wing pattern of most specimens of merarna differs from that in figure 12 in having a more distinct dark mark in the stigma, a slightly less extensive infuscation in the apex of cell R, and the absence of most of the proximal dark ray in cell 1st M2. The specimens examined in this study are extremely variable in the amount of infuscation within the stigma, in the apex of cell R, and in cell 1st M2. The proximal dark ray through cell 1st M2 is entirely lacking in some, whereas in others it is represented only by a spot indicating its termination on vein  $M_3+Cu_1$ ; figure 12 shows the fullest development encountered in this study. As pointed out by Benjamin (1934, p. 55), mevarna is most closely related to dacetoptera, from which it may be separated by the termination of the distal ray through cell 1st  $M_2$  at vein  $M_3+Cu_1$ , by the more acutely pointed hyaline area immediately distad of the stigma, and by the more central position of the marginal hyaline spot at the apex of vein  $R_{2+3}$  in the surrounding dark area. The male wing pattern of merurna is similar to that of the female in all important respects.

F. Van Emden, British Museum (Natural History), upon comparing females from Orlando, Fla., (fig. 12) with the Walker type in the British Museum, stated that the type has a dark infuscation in the apex of cell R, and it is almost fused with the dark area surrounding vein r-m. In addition, he reported that vein r-m is connected to the infuscated spot near the center of cell 1st M<sub>2</sub> by an uninterrupted

dark ray.

#### Trupanea texana Malloch

(Fig. 13)

Trypanca icrana Malloch (nec Hering), 1942, U.S. Natl. Mus. Proc. 92: 4, 5, 18, fig. 1, r (type loc. Arlington, Tex., holotype &, descr., fig. wing ?).

Previously recorded distribution.—Arlington and Dallas, Tex.

Material examined.—Male holotype with the following labels: "Arlington, Texas, 12.XI.07," "Aphanost. skirrob.," "F. C. Bishopp, Collector," and "Type No. 54401, U.S.N.M." Paratypes: Dallas,

Tex., 5 9 9, 24.IV.08; 1 9, 8.V.08.

ARIZONA: 1 &, 2 & 2, Arivaca, 18 miles northwest of Nogales, Rustler's Park, 5 to 26.VII. LOUISIANA: 1 &, Lake Charles, 9.VI.17. NEW MEXICO: 5 & &, 1 &, Alamogordo, Las Cruces, 16 to 26.VI. OKLAHOMA: 2 & &. Stillwater, 14 to 21.VI.54. TEXAS: 6 & &, 11 & &, Catarina, Coleman, El Paso, Giddinas, Juno, Kerrville, Tyler, Waco, 9.V to 8.VII.

The species has been swept from various unidentified grasses and

mesquite.

Location of type.—U.S. National Museum.

Discussion.—The type series of terana shows considerable variation in the posterior terminations of the dark rays through cell 1st  $M_2$ . Some specimens in this study have both rays entire as in ageratae, but in many, as well as in the entire type series, the proximal ray ends at the middle of cell 1st  $M_2$ , and numerous specimens have both these rays ending short of vein  $M_4+Cn_1$ . All specimens of terana in this study were distinguishable from the single male of ageratae by the position of the marginal hyaline spot at the apex of vein  $R_{2*3}$ ; in the former it appears near the middle of the surrounding dark area, whereas in the latter it is closer to the wing apex. Furthermore, all specimens of terana have the two dark rays through cell 1st  $M_2$  of equal width, and every wing shows the slight bulging near the apex of cell  $R_1$  along the costa. The males have no erect anterior midfemoral bristles.

#### Trupanea imperfecta (Coquillett)

(Figs. 14 and 15)

Urcilia imperfecta Coquillett, 1902, N.Y. Ent. Soc. Jour. 10: 181 (type loc. Williams, Ariz., holotype &, descr.).—Adams, 1904, Kans. Univ. Sci. Bul. 2: 450 (in key N.A. spp.).—Aldrich, 1905, Smithsn. Inst. Misc. Collect. 46 (1444); 614 (in list N.A. spp.).

Trypanea imperfecta, Curran, 1932, Amer. Mus. Novitates No. 556: 5 (in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 3, 5, 10, fig. 1, g-h (short descr., figs. wings of and ?).

#### Previously recorded distribution.—Williams, Ariz.

Material examined.—Male holotype with the following labels: "Williams, Ariz., 28.5," "H. S. Barber, Collector," "Type No. 6639, U.S.N.M.," and "Trypanea imperfecta Coq."

ARIZONA: 2 & &, 1 &, Pinery Canyon, Tucson, Williams, 29.V to 26.VII. CALIFORNIA: 9 & &, 17 9 9, 14 localities in southern half of State, February through December. NEVADA: 1 3, 1 2, Glendale, Nelson, 27.IV to 3.X.

The species has been swept from Bebbia juncea var. aspera, Chrysothamnus paniculatus, and Encelia sp., "apparently frutescens var.

Location of type.—U.S. National Museum.

Discussion.—The female is easily distinguished from those of all other Trupanea species by the quadrate hyaline spot immediately anterior to vein m. This spot in every specimen extends the full width of cell R5 and is almost always connected to the hyaline area immediately anterior to it in cell R3. Another unique character is the tendency toward disappearance in the female of the posterior arm of

the apical Y-shaped spot as shown in figure 14.

The wing pattern in males is characterized by much larger hyaline areas, a somewhat more diffuse pattern resulting, with the usual Trupanea-like markings rather obscured. There is never more than a single dark spot near the apex of vein R445 to indicate the apical Y-shaped mark. The hyaline area at the center of cell Rs is almost always present, and the dark ray through cell 1st Me is often broken. The amount of darkening on vein M3+Cu1 is variable. The male holotype has a complete ray through cell 1st M2, and the spot in the center of cell Rs is smaller than that shown in figure 15.

#### Trupanea radifera (Coquillett)

(Figs. 16 and 17)

Urellia radifera Coquillett, 1899, N.Y. Ent. Soc. Jour. 7: 267 (type loc. Tucson, Ariz., holotype o, descr.).

Trypanea radifera, Curran, 1932, Amer. Mus. Novitates No. 556: 5 (in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 3, 6, 11, fig. 1, j-k (short descr., fig. wings o and ?).

Trypanca hebes Curran, 1932, Amer. Mus. Novitates No. 556: 6, 9, fig. 7 (type loc. Buck Creek, Wyo., holotype 2, descr., fig. wing 2).—Mailoch, 1942, U.S. Natl. Mus. Proc. 92: 11 (as synonym of radifera).

Previously recorded distribution.—Of radifera—Alberta (Canada) and Arizona, Colorado, Idaho, New Mexico, South Dakota, and Texas; of hebes-Wyoming.

Material examined.—Holotype 2 with the following labels: "Buck Creek, Wyo., VIII.14.95," "W. M. Wheeler Collection," and

"Trypanea hebes Curran 2."

ARIZONA: 3 & &, 6 & Q, Chiricahua Mountains, 15 miles west of Gila Bend, Littlefields, Tucson, 22.VII to 8.XII. CALIFORNIA: 13 & &, 28 & Q, 25 localities throughout State, January through December. COLORADO: 1 &, 7 & Q, Fort Collins, Peaceful Valley, Tennessee Pass, Wilkerson Pass, 6.VII to 4.IX. IDAHO: 1 &, 2 & Q, Burley, Hollister, 10.VI to 21.VII. KANSAS: 1 &, Manhattan, 5.IX.39. NEBRASKA: 3 & &, Arapaho, Ravenna, 4 to 10.VII.53. NEVADA: 1 Q, Glendale, 5.VI.30. NEW MEXICO: 3 & &, 7 & Q, 10 localities throughout State, 29.V to 14.X. SOUTH DAKOTA: 1 &, White River, 28.VIII.13. TEXAS: 4 & &, 4 & Q, Brewster County, Clarendon, 13.VI to 31.VII. UTAH: 2 & &, 2 & Q, Uintah County. WYOMING: 2 & &, 4 & Q, Lance Creek, 28 miles south of Newcastle, Redbird, Teton County, 8.VI to 18.VIII.

Location of types.—Of radifera—U.S. National Museum specimen

lost; of hebes—American Museum of Natural History.

**Discussion.**—T. radifera is a widespread western species belonging to the group in which the apex of cell R is entirely hyaline. The wing pattern in females is distinctive in that the dark ray from the stigma to vein r-m is always broken in cell  $R_1$ , but it may be complete through the stigma itself, unlike the condition shown in figure 16. There is always a distinct ray or partial ray through cell 1st  $M_2$ , and the dark mark in the center of vein  $M_3 + Cu_1$  varies from triangular to rectangular, but if rectangular, it is never more than four times as long as wide. Females are easily separable from those of eclipta by their geographic distribution, the nature of the break in the dark ray from the stigma to vein r-m, and the presence of a dark spot on vein  $M_3 + Cu_1$ . No males of radifera seen in this study possess a ray from vein  $R_1$  to vein r-m; they are most easily distinguished from males of other species in this group by this character alone.

#### Trupanea eclipta Benjamin

(Fig. 18)

Trupanca (Trupanca) celipta Benjamin, 1934, U.S. Dept. Agr. Tech. Bul. 401: 57, fig. 42, A-K (type loc. Orlando, Fla., holotype &, descr., figs. wing & and \$\varphi\$, larva).

Previously recorded distribution.—Florida.

Material examined.—Holotype & with the following labels: "Nov. 1, Orlando, Fla.," "bred from Eclipta alba," "D. J. Nicholson, Collector," and "Type No. 54383, U.S.N.M."

FLORIDA: 85 & &, 97 9 9, Fort Pierce (Orlando), 16.VIII to

29.XII,

Location of type.—U.S. National Museum.

**Discussion.**—This species is easily distinguished from all other species in the group having the apex of cell R hyaline, by the break in the dark ray from the stigma to vein r-m, which occurs in cell  $R_3$ . The wing pattern of the *eclipta* male resembles that of the female in every important respect and may be easily distinguished from that of the very different *radifera* (fig. 17).

#### Trupanea jonesi Curran

(Figs. 19 and 20)

Trypanca jonesi Curran, 1982, Amer. Mus. Novitates No. 556: 6, fig. 6 (type loc. Corvallis, Oreg., holotype 9, descr., fig. wing 9, in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 6, 15, fig. 1, u (short descr., fig. wing 9).
 Trypanca microstigma Curran, 1982, Amer. Mus. Novitates No. 556: 6, 7, fig. 8

Prypanca microstiyma Curran, 1932. Amer. Mus. Novitates No. 556; 6, 7, fig. 8 (type loc. Crater Lake, Oreg., holotype \$, descr., fig. wing, in key N.A. spp.).— Malloch, 1942. U.S. Natl. Mus. Proc. 92; 3, 6, 11, fig. 1, 1-m (short descr., figs. wings \$\delta\$ and \$\delta\$). NEW SYNONYMY.

Previously recorded distribution.—Of jonesi—California, Nevada, Oregon, and Wyoming; of microstigma—California, Idaho, Nevada, and Oregon.

Material examined.—Holotype 2 with the following labels: "Corvallis. Ore., Aug. 10, 1931." "reared fr. Aster douglasii Lindl.." "S. C. Jones, Coll.," and "Trypanea jonesi Curran. 2, type." Holotype 2 with the following labels: "Crater Lake, Ore., So. Rim, 7100'. July 29, 1930." "H. H. Scullen, Coll.," and "Trypanea microstigma

Curran, type.

ARIZONA: 1 2, Lee Siding, 27.VIII.37. CALIFORNIA: 55 & 232 9 9, 107 localities throughout State, every month of the year. COLORADO: 2 & 3, 1 9, 7 miles south of Glade Park, Longmont, Ukiah Grade, 10.V to 14.IX. IDAHO: 1 & 21 9 9, 14 localities throughout State, 2.VII to 14.IX. MONTANA: 1 2, Glacier National Park, 26.VII.36. NEVADA: 25 & 3, 26 9 9, Austin, Carson City, Ely, Glendale, Ormsby County, Wells, 14.II to 13.VIII. NEW MEXICO: 5 9 9, Alamogordo, Santa Rosa, 9.IV to 28.VI. OREGON: 4 9 9. Devils Lake, Mount Hood, 12.VII to 8.VIII. TEXAS: 1 9, between La Tuna and Vinton, 29.VIII.37. UTAH: 34 & 3, 42 9 9, 10 localities throughout State, 12.V to 27.IX. WYOMING: 2 & 6, 5 9 9, Big Horn County, Dubois, Fort Bridger, Teton County, Yellowstone National Park, 18.VI to 6.IX.

The species has been reaved from Corcopsis sp. Adults have been collected from Achillea sp., Agropyron cristatum, Aplopappus linearifolius, Atriplex polycarpa, Baccharis sergiloides, Bacria chrysostoma, Chrysothamnus nauscosus, Corcopsis calliopsidea, Croton californicus, Eriogonum sp., Erodium cicutarium, Layia platyglossa, Lepidospartum squamatum, Medicago sativa, Monolopia major, Phacelia sp., Pluchea sericca, Salsola kali vav. pestifer, S. kali vav. tennifolia,

and Wyethia sp.

Location of types.—()f jonesi and microstigma—American Museum

of Natural History.

**Discussion.**—A very close study of the Curran types of *jonesi* and *microstigma* based on structural characters leaves no doubt that the two are conspecific. This conclusion is verified by a further examination of a large number of specimens from California and other Western States. In that series there is every possible variation in the completeness of the dark ray through ceil 1st  $M_2$ —entire in females of *jonesi* and completely broken in that cell in *microstigma*. The clongate nature of the dark spot on vein  $M_3 \pm Cu_4$  is a very constant feature of the wing pattern, and this, together with the unbroken dark ray from vein  $R_4$  to vein r-m, distinguishes females from

all those species belonging to the group having the apex of cell R entirely hyaline. Males of *jonesi* also have an elongate streak on vein  $M_a+Cu_1$  but lack the ray from vein  $R_1$  to vein r-m, and the apical Y-shaped mark is always incomplete or completely absent. Females of pseudovicina, the closest relative, have a triangular infuscation on vein  $M_a+Cu_1$ , and the marginal hyaline spot at the apex of vein  $R_{2*3}$  is closer to the center of the surrounding dark area than in *jonesi*, whereas the wing pattern of the pseudovicina male differs in no important respects from that of the female.

#### Trupanea californica Malloch

(Fig. 21)

Trypanca californica Malloch, 1942, U.S. Natl. Mus. Proc. 92: 4, 6, 17 (type loc. Emerald River (Tahoe, Calif.), holotype ?, descr.).
Trypanca microsciulosa Malloch, 1942, ibid. 92: 4, 6, 17 (type loc. Lakeside (Tahoe, Calif.), holotype &). NEW SYNONYMY.

Previously recorded distribution.—Of californica—Emerald River; of microsetulosa—Lakeside; both in Tahoe, Calif.

Material examined.—Holotype & with the following labels: "Emerald R., Tahoe, Carif., June 30, '27," "J. M. Aldrich, Coll.," "Type No. 54399, U.S.N.M.," and "californica type." Paratypes of californica: 2 & & . 1 & . same data as type: 1 & . Fallen Leaf. Calif., 6500' elevation, 15.VII.17: 1 & . San Francisco, Calif., 12.X.19: 1 & . Kerrville, Tex., 30.V.04. Holotype & with the following labels: "Lakeside, Tahoe, Calif.," "J. M. Aldrich, Coll., VI.1927," "Type No. 54400, U.S.N.M.," and "microsetulosa."

ARIZONA: 3 & & , 5 & 2 , Cochise County, 6 miles south of Dos Cabezos, Felton, Globe, Rustler's Peak, Santa Catalina Mountains, 15.V to 10.IX. (ALIFORNIA: 57 & & , 29 & 2 & , 45 localities throughout State, May to November. COLORADO: 1 & NEVADA: 1 & Austin, 12.VIII.40. NEW MEXICO: 18 & & , 18 & 2 , 16 localities throughout State, June to August. TEXAS: 7 & & , 4 & 2 , Brewster County, Enchanted Rock, Fort Stockton, Kerrville, Marta, Van Horn, Waco, 1.IV to 27.X. WASHINGTON: 1 & . near La Connor, 28.VI.43.

Reared from larvae in flowers of Gnaphalium sp. in California and collected there and elsewhere from Artemisia sp., Parthenium argentutum, Prunus emarginata, seed cabbage (presumably Brassica oleracea var. capitata), and Nolanum clacagnifolium.

**Location of types.**—Of *microsciulosa* and holotype and paratypes of *californica*—U.S. National Museum.

**Discussion.**—I am unable to find any differences between the holotypes of californica and microsetulosa other than the more extensively bristled vein  $R_{1+5}$  of the latter mentioned by Malloch (1943). Both holotypes are from the Tahoe region of California, as are several of the paratypes of californica. T. californica is easily distinguished from actinobola by the close proximity of the marginal hyaline spot at the apex of vein  $R_{2+5}$  to the distal margin of the surrounding dark area; a short ray is produced between that spot and the distal margin of about the same width as that lying upon vein m.

#### Trupanea pseudovicina Hering

(Fig. 22)

Trypanca texana Hering (nec Malloch), 1942, Siruna Seva, Folge 4: 29, fig. 18 (type loc. Dallas, Tex., holotype 6, fig. wing).
Trypanca pseudoricina Hering, 1947, ibid. 6: 12 (new name for texana Hering, nec Malloch).

Previously recorded distribution.—Dallas, Tex.

Material examined.—ARIZONA: 5 & &, 1 &, Florence Junction, Rillito, Santa Catalina Mountains, Sasaba, Tucson, 5.IV to 17.X. CALIFORNIA: 5 & &, 6 & &, China Flat (El Dorado County). 12 miles southeast of Ivanpah (San Bernardino County), Oasis Nature Area (Joshua Tree National Monument), Palm Springs (Riverside County), San Diego, San Ysidro, Santa Monica, Whitewater Canyon, Wood Lake (Tulare County), 2.I to 22.XII. NEW MEXICO: 2 & &, Las Vegas Hot Springs, Socorro, 8.VIII. TEXAS: 1 &, Brewster County, 13 to 17.VI.08.

No host data are available, but the species has been caught in traps baited for the Mexican truit fly (Anastrepha ludens (Loew)) and in rotary traps in California.

Location of type.—Not known.

**Discussion.**—Females of pseudovicina so closely resemble those of jonesi that at first glance they may be confused easily. The former species at the middle of vein  $M_3+Cu_1$  has a triangular infuscation that is never clongated along that vein; the hyaline marginal spot at the apex of vein  $R_{2\cdot 3}$  is smaller and located closer to the center of the surrounding dark area; the ovipositor sheath is much shorter; and the head is slightly higher than long from the lateral aspect in contrast to that of jonesi, in which it is slightly longer than high. The wing pattern of the pseudovicina male differs in no important respect from that of the female, and therefore it may be distinguished easily from that of the jonesi male.

#### Trupanea signata, new species

(Fig. 23)

Head.—Distinctly higher than long from lateral aspect; antennae about three-fourths times as long as face, apex of third segment somewhat darker than remainder of segment, arista rather dark; front slightly grayish pollinose, at vertex 1½ times as wide as width of one eye, very slightly longer than width at vertex; three pairs lower fronto-orbitals, anterior pair distinctly weaker than other two and about one-half times as long as middle pair; ocellars strongly proclinate and distinctly longer than posterior pair of fronto-orbitals.

Thorax.—Mesothorax, scutellum, and pleural sclerites heavily and very dark-gray pollinose, disk of mesothorax and lateral surfaces of scutellum with short rather stout golden hairs, other bristles shining brownish black: humeri and extreme lateral margins of mesothorax with tendency to be yellowish, but never distinctly so. Legs entirely yellow with yellow to light-brown femoral and tibial setae. Wing pattern (fig. 23, holotype 2) consisting of typical preapical dark-brown area; complete narrow ray from stigma to vein r-m, this ray

often lighter or almost completely absent within stigma; distinct well-defined dark spot in apex of cell R of variable size, but almost always separated from infuscation lying upon vein r-m by unbroken hyaline area so as to leave no connection between two dark areas; hyaline spot immediately distad of vein r-m narrow but always rather distinct and extending from two-thirds to completely across cell R<sub>5</sub>: marginal hyaline spot at apex of vein R<sub>2+3</sub> situated so as to leave dark ray between it and distal margin of surrounding dark area 11/2 to 2 times as wide as dark ray covering vein m; one dark ray across cell 1st M2, usually ending at vein M3+Cu1, but in some specimens short of that vein; and extremely short dark part of infuscation lying upon vein r-m extending posteriorly into cell 1st M2 in direction of midpoint of vein  $M_3 + Cu_3$ , at which point there is dark infuscation two to four times as long as wide lying on vein; basal half of wing completely hyaline, except for darkening of basal fourth of vein  $Cu_2+2d$  A.

Abdomen.—Color, pollinosity, and setation as on mesothorax and scutellum; ovipositor sheath brownish black to black, about 21/4 to 21/2 times as long as two preceding abdominal tergites, covered dorsally with fine pale setae, which are somewhat longer and stouter on proximal half than on distal half; external male genitalia shining brownish black to black.

Types and material examined.—Holotype 2 with the following labels: "Covina, L. A. Co., Calif., 22.V.51," "reared fr. Gnaphalium chilense," and "C. Henne, Collector." Paratypes as follows (all Calif., except where noted): 7 & &, 2 9 9, same data as type (Los Angeles County Museum); 1 9, Berkeley, 26.V.07 (California Insect Survey); 1 2, Brookings, Oreg., 6-7.VII.51 (California Academy of Sciences); 1 &, 2 & 2, Coalinga, 12.X.58 (U.S. National Museum); 2 & &, Firebaugh, 22.IV.48 (California Insect Survey); 1 &, Freestone, 7.IX.50 (California Department of Agriculture); 1 &, Idyll-wild, San Jacinto Mountains, 16.VI.40 (California Insect Survey); 1 8, 2 9 9, Lake Anza, Oakland Hills, 19.X.50 (California Insect Survey and U.S. National Museum); 1 2, Oakland, 3.IV.50 (U.S. National Museum); 1 3, Sacramento, 4.IV.29 (California Department of Agriculture); 1 2, San Benito County, VIII.56, ex NH<sub>3</sub> walnut husk fly trap (California Department of Agriculture); San Francisco, 2 & &, 1 &, 23.IV.09 (California Academy of Sciences and California Insect Survey), 1 &, 20.X.19 (California Insect Survey); Sun Francisco, reared ex Anaphalis, 2 & &, 2 & 2, 1.111.34 (California Department of Agriculture); 1 &, 3 & \$, San Francisco. 27.VIII.36 (California Department of Agriculture); 3 & \$,5 9 9, 5.X.37 (U.S. National Museum); 2 & \$, Snowline Camp, El Dorado County, 7.VII.48 (California Insect Survey and U.S. National Museum); 1 9, Solano County, 24.VI.50, citronella bait tran (California Department of Agriculture); 4 & & , 2 9 9, Tahquitz, Riverside County, 14.III.38, on "everlusting" (San Diego Natural History Museum); 1 &, Triniti, 10.I.38 (California Insect Survey): Wood Lake, rotary trap, 1 9, 31.III.47, 1 8, 16.V.47, 1 9, 26.V.47, 1 9, XI.47 (California Insect Survey).

Additional material as follows: ARIZONA: 1 9, Mount Lemmon, 16.VI.57. CALIFORNIA: 1 9, Fallbrook (San Diego County), 14.VIII.58. OREGON: 2 99, Brookings (Curry County), 6

to 7.VII.51; 1 9, Clatsop, 17.VII.25, collected by Dellinger bag. TEXAS: 1 \$, 2 9 9, Clarendon, 19.IX.05, on Grindelia squarrosa; 1 9, Marfa, 6.IV.09.

Location of type.—California Academy of Sciences.

**Discussion.**—The marginal hyaline spot at the apex of vein  $R_{2+3}$  is separated from the next distal hyaline area by a short dark ray at least as wide to two times as wide as the dark ray over vein m. Most specimens in this study were easily separated by means of this character from *californica*, in which this short ray is rarely wider than that over vein m. In addition, the infuscation in the distal end of cell R is very distinctly margined in *signata*, whereas in *californica* the infuscation is present but indistinct. T. pseudovicina is closely related, but it possesses no infuscation in the apex of cell R and the marginal hyaline spot at the apex of cell  $R_{2+3}$  is smaller and farther removed from the next distal hyaline area.

#### Trupanea actinobola (Loew)

(Fig. 24)

Trypeta actinobola Loew, 1873, Smithsn. Inst. Misc. Collect. 11 (256): 326 (type loc. Tex., holotype &, descr.).

10c. Tex., nontype 5, descr.).
11c. Urcllia actinobola, Loew, 1873, ibid. 11 (256); 326 (transfers to Urcllia).—
11c. Coquillett, 1899, N.Y. Ent. Soc. Jour. 7; 266 (mistakenly as synonym of mevarna Walk.).—Snow. 1903, Kans. Univ. Sci. Bul. 2; 219 (in list Dipt. Kans.).—Adams, 1904, ibid. 2; 450 (in key N.A. spp.).—Aldrich, 1905, Smithsn. Inst. Misc. Collect. 46 (1444); 613 (in list N.A. spp.).

Trypeta (Urellia) actinobola, Osten Sacken, 1878, ibid. 16 (270): 194 (refs.).
Trypanca actinobola, Curran, 1932, Amer. Mus. Novitates No. 556: 6 (in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 4, 6, 16, fig. 1, x (short descr.. fig. wing §).

Trupanca (Trupanca) actinobola, Beujamin, 1934, U.S. Dept. Agr. Tech. Bul. 401: 56, fig. 41, A-K (descr., discuss., figs. wings / and ?).

Previously recorded distribution.—Mexico and Arkansas, California, Florida, Georgia, Indiana, Kansas, Massachusetts, Nebraska, New Mexico, Rhode Island, and Texas.

Material examined.—Lectotype here selected is a male in the series of Loew cotypes with the following labels: "Texas, Lefv.," "94," "Loew Coll.," "Type 13321," and "used by Benjamin (1934) as type of name actinobola."

TEXAS: 11 &, 12 9 9, 12 localities throughout State, 3.IV to 17.IX. UTAH: 2 & &, 3 9 9, Bellevue, Blue Creek, Brigham, Leeds, St. George, 30.V to 12.IX. VIRGINIA: 1 &, Kearney, 25.V.36. WYOMING: 1 &, 1 9, Lance Creek, 28 miles south of Newcastle, 14 to 18 VIII.

Adults have been collected from Gutierrezia lucida, G. sarothrae, Hymenoclea sulsola, and Pluchea sericea in various States. They have also been reared in Florida from larvae in flowers of Actinospermum sp., Aster adnatus, Erigeron quercifolius, E. vernus, Hieracium sp.,

Solidago chapmanii, S. serotina, and S. sp.

Location of type.—Museum of Comparative Zoology, Harvard University.

Discussion.—T. actinobola is an extremely variable and widespread species with a single ray through cell 1st M2, commonly ending short of vein M3+Cu1, the apex of cell R with or without infuscation, and with or without a spot at the center of vein  $M_3 + Cu_1$ . Curvan (1932) keys actinobola by the presence of a spot on vein M3+Cu1, but many specimens have this character on one wing and not on the other, or the spot may be absent on both wings. T. actinobola may be recognized most easily among closely related species by the head, which in both sexes is about as long as high with a rather flat front in profile. The wing (fig. 24) is from a New York specimen but resembles that of the Texas type in every important respect, except that in the latter the hyaline area in the extreme base of cell R5 is more diffuse and occupies more of the cell width.

T. actinobola may be distinguished from californica, principally by its shorter ovipositor (usually determined only by a side-by-side comparison of females of the two species) and more easily by the position of the marginal hyaline spot at the apex of vein  $R_{2+3}$ . In actinobola this spot forms, with the distal margin of the surrounding dark area, a short ray more than twice as wide as that over vein m, whereas in californica (fig. 21) this spot is usually much closer to the next distal hyaline area. T. californica is apparently restricted to the Western States, where its separation from the more widely distributed actinobola is more difficult than can be made outside that area on the basis

of geographic distribution,

Possibly a statistical study based on a much larger number of specimens than are now available would show the presence of several subspecies on the North American Continent. The material is not now adequate to demonstrate the presence of discontinuities and/or intergrades within the concept of the species as presented in this study.

#### *Trupanea vicina* (van der Wulp)

(Fig. 25)

Urctlia vicina van der Wulp, 1899, in Salvin and Godman, Biol. Cent.-Amer. 2: 427, fig. (type loc. Orizaba, Mex., descr. from 2 99, fig. wing).—Snow, 1904, Kans, Univ. Sci. Bul. 2: 345 (in list Dipt. Ariz.).—Adams, 1904, ibid. 2: 450 (in key N.A. spp.).—Aldrich, 1905, Smithsn. Inst. Misc. Collect. 46 (1444); 614 (in list N.A. spp.) .- Cresson, 1907, Amer. Ent. Soc. Trans. 33: 106 (brief descr.).

Trypanca vicina, Curran, 1932, Amer. Mus. Novitates No. 556: 6 (in key N.A. spp.).—Malloch, 1942, U.S. Natl. Mus. Proc. 92: 6, 13, fig. 1, q (descr., fig. wing \( \varphi \)).

Previously recorded distribution.—Orizaba and Gulf of California (Mex.) and Arizona, New Mexico, and Texas.

Material examined.—ARIZONA: 1 \$, 5 \$ \$, Bill Williams Fork, Chiricahua Mountains, 12.VII to 7.VIII. CALIFORNIA: 1 \$, 4 \$ \$, La Jolla, San Diego, 20.VI to 13.VII. NEW MEXICO: 15 \$ \$, 15 \$ \$, Alamogordo (Bernalillo County), Cloudcroft, La Luz, Las Cruces, Las Vegas, Steins, Tajique, 25 miles west of Tularosa, 22.IV to 8.VIII. TEXAS: 4 \$ \$, 8 \$ \$, Austin, Big Bend National Park, Brewster County, Chisos Mountains, Crystal City, Victoria, 4.II to 6.IX.

Adults have been reared from larvae in the flowers of marigold and have been collected from spinach, tumbleweed, and Sphaeralcea anaustifolia.

Location of type.—British Museum (Natural History).

**Discussion.**—A specimen resembling Trupanea vicina was compared with the type of that species by F. Van Emden, British Museum (Natural History). The pattern of the right wing of the Crystal City specimen (fig. 25), according to Van Emden, differs in no important respect from that of either type. The most distinctive feature of this wing pattern is the extensive evenly dark nonareolate infuscation in the apex of cell R and the characteristic manner in which the dark ray through the stigma tends to run into it rather than more obliquely to vein r-m. In addition, the marginal hyaline spot at the apex of vein  $R_{2+8}$  is more or less centered in the dark area on each side of it. Van der Wulp's figure is misleading in indicating both these characters are otherwise, but his illustration of an incomplete ray through cell 1st  $M_2$  is well within the range of variation I have seen. Malloch's figure (1942) is a much more accurate representation of the wing pattern of vicina.
