Supply and Demand for Livestock Credit in Sub-Saharan Africa: Lessons for Designing **New Credit Schemes**

M. A. JABBAR, S. K. EHUI and R. VON KAUFMANN * International Livestock Research Institute (ILRI), P.O. Box 5689, Addis Ababa, Ethiopia

Summary. — Based on analysis of credit supply in Ethiopia, Kenya, Uganda and Nigeria, it is shown that public credit institutions do not have sufficient funds to meet the demand for livestock credit and cannot mobilize savings from their clients or other commercial sources for one reason or another. In addition, available credit does not reach those who need it the most and with whom it could have the greatest impact due to the application of inappropriate screening procedures and criteria to determine creditworthiness. The analysis of demand based on borrowing and nonborrowing sample households using improved dairy technology, it is shown that not all borrowers borrowed due to liquidity constraint while some borrowers and some nonborrowers had liquidity constraint but did not have access to adequate credit. Logistic regression analysis show that sex and education of the household head, training in dairy, prevalence of outstanding loan and the number of improved cattle on the farm had significant influence on both borrowing and liquidity status of a household, though the degree and direction of influence were not always the same in each study country. Based on the findings it is suggested that combining public and commercial finance could solve the problem of inadequate credit supply while inventory finance to community level input suppliers and service providers might help in getting credit to worthy and needy smallholders at lower cost than providing credit to smallholders directly. © 2002 Published by Elsevier Science Ltd.

Key words — Africa, Nigeria, Ethiopia, Uganda, Kenya, credit, livestock

1. OBJECTIVES AND BACKGROUND

This paper reports the results of a study 30 conducted in four countries in sub-Saharan Africa to: (a) assess the extent to which formal agricultural credit institutions target smallholder livestock producers, the mechanisms they use for selecting borrowers and delivering credit, and the volume, type, purpose and conditions of their livestock loans, and the nature of benefits for the borrowers; (b) determine the factors that influence the demand for livestock credit, particularly for dairy production, and to assess the role of credit relative to the liquidity status of the borrower; and (c) discuss the implications of the findings for designing new credit schemes to overcome the major deficiencies of the existing systems.

Smallholders are typically trapped in poverty because they do not have the money required to invest in income-enhancing innovations. This 47 constraint has been addressed by a variety of 48 smallholder credit schemes and a number of 49 studies have found positive correlations be- 50 tween supplies of credit from formal credit in- 51 stitutions 1 and expenditure on modern inputs 52 such as improved seeds, irrigation and fertilizer 53

^{*}The authors are grateful to two anonymous referees who commented on an earlier version of this paper. The revised version benefited from comments of participants at the Workshop on Structured Short and Medium Term Finance to Small Scale Farmers in Africa, organized by the Common Fund for Commodities, Nairobi, Kenya, April 4-6, 2001. The African Development Bank and ILRI funded fieldwork for the study. However, the authors alone are responsible for the content of this paper. Final revision accepted: 6 February 2002.

WORLD DEVELOPMENT

that resulted in increased agricultural output (Braverman & Guasch, 1986; Desai & Mellor, 1993; Malik, Mushtaq, & Gill, 1991). In this way formal credit played a major role in the wide scale adoption of improved technologies that led to the Green Revolution. It has been shown that formal credit increases in importance relative to informal credit as economies develop and new technologies are adopted (Desai & Mellor, 1993; Heidhues, 1995).

There is less empirical evidence on the role of credit in the smallholder livestock sector. For example, contrary to expectations, the Grameen Bank in Bangladesh extends as much as 40– 50% of its loans to landless and poor farmers to acquire and raise livestock. The incentive for this is livestock's potential for generating regular incomes and realizable assets that are essential to enabling the beneficiaries to stay out of poverty in times of adversity. Processing and marketing of livestock products are also especially attractive to women borrowers. But these farmers rarely adopt improved livestock technologies leaving untapped much of the potential of the animals they purchase. A recent study in East Africa has shown that credit has a higher potential for impact through higher input use and milk yield if targeted to liquidityconstrained farms than otherwise (Freeman, Ehui, & Jabbar, 1998). A better understanding of the role of credit in the adoption of livestock technology in sub-Saharan Africa is urgently required to make it more effective in improving the livelihoods of resource-poor livestock owners and low-income consumers of livestock products.

During the 1970s and early 1980s, growth in the demand for meat and milk in sub-Saharan Africa outstripped supply partly because of subsidized imports, particularly that of milk. Thereafter, as productivity continued to decline, the deficit could not be made up by imports because of falling foreign exchange reserves and consumers had less meat and milk on their tables. Projections to 2020 indicate continued rising demand for animal products with corresponding deficits, unless productivity can be improved significantly (Delgado, Rosegrant, Steinfeld, Ehui, & Courbois, 1999). This deficit is an important issue because, apart from providing high-value food, the livestock sector contributes substantially to the economies of sub-Saharan countries by providing income, employment and foreign exchange. They contribute to sustainable agricultural production with inputs and services such as draught power, manure and transportation for crop production. Livestock products—meat, milk, eggs, 111 wool, hides and skins—on average account for 112 28% of agricultural GDP of sub-Saharan Af- 113 rican countries. This share increases to about 114 35% when the value of animal traction, trans- 115 port and manure are included. In addition, the 116 share increases as agriculture intensifies. In 117 summary, the livestock sector is a vital com- 118 ponent of national development with multiplier 119 effects in processing and marketing which is 120 falling far short of its potential (Winrock, 121 1992).

Since the early 1990s, the introduction of 123 structural adjustment programs led to a re- 124 duction of real expenditure on agriculture. This 125 included falling supplies of agricultural credit, 126 which reduced uptake of innovations by the 127 majority of resource-poor smallholders. Live- 128 stock technology adoption has probably suf- 129 fered proportionately more in this process (De 130) Haan, 1995) because livestock enterprises such 131 as those involving high-yielding crossbred dairy 132 cows require high initial outlays to acquire the 133 animals and construct housing and install other 134 infrastructure. They also require substantial 135 working capital. Furthermore, in contrast to 136 annual crops, it takes several years to raise in- 137 come from investment in livestock production; 138 meanwhile substantial expenses are incurred in, 139 for example, maintaining maturing animals.

In this paper, the supply and demand side 141 issues related to livestock credit are analysed 142 based on field surveys in four countries. In 143 Section 2, sampling and data sources are de-144 scribed. In Section 3, the issues related to credit 145 supply are discussed. In Section 4, the current 146 extent of borrowing and liquidity constraint, 147 and the determinants of being borrowers and 148 being liquidity constraints are discussed. In 149 Section 5, the findings are summarized and 150 their implications for designing new credit 151 schemes are discussed with an illustration.

2. SOURCES OF DATA

In order to assess the issues related to the 154 supply of credit to smallholder livestock pro- 155 ducers, information was collected from the 156 principal agricultural credit institutions in 157 Uganda, Ethiopia and Nigeria in 1992. These 158 were the Uganda Commercial Bank (UCB), the 159 Agricultural and Industrial Development Bank 160 (AIDB) in Ethiopia, and the Nigerian Agri- 161 cultural and Cooperative Bank (NACB). In 162

each country, structured questionnaires were mailed to the selected branches in predominantly livestock producing areas. A senior bank official provided the required information from individual borrower records and other relevant bank documents. The responses included information on the borrowers' assets such as herd size, crop and grazing lands, how they got credit, the prerequisites for loan approval, what they used it for, the loan characteristics such as the amount, interest rate, length of grace periods, the repayment period, and collateral.

In order to determine the demand for credit among smallholder dairy producers, data were collected through crosssectional surveys among farmers in Ethiopia, Kenya and Uganda. Particular attention was given to dairy farmers because dairying is an important agricultural subsector in the selected countries and improved dairy technologies (crossbred cows, improved feeds and management etc.) are already in use. Further expansion of these technologies is being promoted through development projects in which credit could be an important component. Credit is expected to raise dairy productivity through enabling smallholders to invest in productivity increasing inputs. The results of the surveys were expected to contribute to designing better development projects that target borrowers more objectively, and assisting governments in formulating enabling policies for livestock development.

A two-stage sampling procedure was followed for the farm surveys in Selale and Debre Libanos Awrajas (districts) in Ethiopia, Githunguri and Limuru divisions in Kiambu district in Kenya, and Mukono and Mpigi districts in the central region of Uganda. The sites were purposively selected in locations with histories of improved smallholder dairying and the use of credit. A one-page questionnaire on herd inventory was administered to all the households in the selected study locations. This generated information from 2,630 households in Ethiopia, 1,225 in Kenya and 500 in Uganda. Farms having at least one dairy cow were identified, out of which random samples were drawn for detailed survey. Data were collected from 75 households in Ethiopia, 94 in Kenya and 73 in Uganda during November 1992-April 1994 by structured questionnaires (for details see, Freeman, Jabbar, & Ehui, 1998).

3. SUPPLY OF INSTITUTIONAL LIVESTOCK CREDIT FOR SMALLHOLDERS

(a) Credit delivery mechanisms

In Uganda, the most important source of 220 formal credit for smallholder livestock farmers 221 was the government-owned UCB, a multipur- 222 pose bank providing loans to industry, trans- 223 portation, commerce and agriculture. The 224 Rural Farmers Scheme (RFS), a specialized 225 scheme for integrated rural development, was 226 the primary channel in the UCB for lending to 227 smallholders. Although RFS incorporated as- 228 pects of small-scale agro-industry, rural trans- 229 port and rural housing, most of the lending was 230 for agricultural production. RFS's funds were 231 provided by the African Development Fund at 232 a nominal service charge of 0.75% per annum. 233 The remaining funds were grants from the 234 government to cover administrative costs.

In 1992, UCB had 10 regional offices and 185 236 local branches, and RFS engaged 22% of the 237 bank's branches and 5% of its current staff. 238 Potential borrowers were not required to pro- 239 vide collateral but the local council was re- 240 quired to certify their credit worthiness. In 241 addition, loan applicants had to provide evi- 242 dence of prior experience with livestock hus- 243 bandry and ownership of some livestock- 244 related infrastructures such as barns.

To avoid diversion of loan funds to nonapproved activities, the RFS disbursed most loans 247 in kind and very little in cash. For example, 248 over 90% of the livestock-related loans dispursed in 1991–92 were in the form of live analysis or materials for fencing. The few cash 251 loans given were mainly intended for payment 252 of hired labor. The nominal interest rates 253 charged to borrowers under the RFS were 37% 254 and 32% per annum for unsecured and secured 255 loans, respectively. These translated into real 256 interest rates of, respectively, -10.1% and 257 -13.4%. ²

In Ethiopia, the government-owned AIDB 259 was the principal source of agricultural credit 260 including loans for livestock. The bank offered 261 short-term (one year), medium-term (2–5 years) 262 and long-term (over five years) credit to private 263 and public investors in the agricultural and 264 industrial sectors. Its lending portfolio as of 265 June 1992 was 77% to agriculture, 17% to in- 266 dustry and 6% to other sectors. It received its 267 funds directly from the state treasury and in- 268 directly through specific lines of credit from 269

WORLD DEVELOPMENT

external donors. It was not allowed to mobilize savings from the public. In 1992, AIDB ac-

counted for 99% of the total volume of rural credit from the formal sector; the Commercial Bank of Ethiopia disbursed the remaining 1%.

In 1992, AIDB had a network of 11 branches and 19 subbranches. Its lending policies were directed by the central bank, the National Bank of Ethiopia (NBE) whose Board of Directors was also the governing board of AIDB. Lending policies were not always dictated by commercial considerations. For example, as of June 1992, the bank had extended about 90% of its agricultural loan portfolio in unsecured loans to state farms and cooperatives, which owed 97% of all delinquent loans.

During 1982–92, agricultural loans constituted 62% of all approved loans by AIDB, and the smallholder sector accounted for only 9% of total rural loans (Tilahun, 1994). Of the agricultural loan portfolio, 94% was allocated to the crop sector and 6% to livestock. About 76% of livestock loans were allocated to government farms, 22% to service cooperatives and 1% each to producer cooperatives and private individuals.

AIDB had a two-tier system in which credit funds were advanced to Service Cooperatives for lending to farmers through their Peasant Associations (PAs). As the primary borrowers, Service Cooperatives were responsible for determining their members' creditworthiness and ability to repay. Service Cooperatives were provided two types of incentives by AIDB to encourage vigorous loan collection. A service cooperative was allowed to generate revenue by adding up to 2% to the bank's basic 5% interest rate. It would receive fresh loans only when outstanding loans were fully repaid by its borrowing members. The service cooperatives were expected to extend this requirement to the individual PAs as well. In recent years, government policy reforms have led to restructuring of the cooperative system. Almost all producer cooperatives have been dissolved while large number of service cooperatives are either nonfunctional or were expected to be liquidated.

NGOs such as the Finnish Development Aid Agency FINNIDA and the Canadian Physicians for Aid and Relief have also been providing smallholder livestock credit. In most cases these loans were provided in kind except for a few loans for cattle fattening that were given in cash. AIDB branches usually administered these loans on behalf of the NGOs. At the time of the survey in 1992, AIDB did not

have any regular credit program for livestock 326 farmers. 327

Interest charged on loans was fixed by the 328 central bank. Prior to 1992, the nominal inter-329 est rate on lending ranged between 5% and 7% 330 per annum with preferential rates for state-331 owned enterprises and cooperatives. In 1992, as 332 part of financial sector reforms, interest rates 333 were increased to between 11% and 11.5% per 334 annum and preferential rates were abolished. 335 Lending rates have changed periodically since 336 1992. The real interest rate in 1992 was 0.9%. 337 In September 1994, the lending rate on all types 338 of loans was between 14% and 15% per annum. 339

In Nigeria, the primary supplier of livestock 340 credit was the NACB, which was established by 341 the Federal Government in 1973 to provide 342 agricultural loans to individual farmers, cooperatives, limited liability companies, state and 344 federal government agencies. The NACB relied 345 entirely on the government or donors for its 346 funds. It did not mobilize any savings from its 347 clients. As of January 1993, NACB had nine 348 departments, five zonal offices, over 50 branches and about 300 representatives throughout 350 the country.

The NACB had two operational schemes for 352 lending to smallholders. One was the small- 353 holder direct loan scheme under which loans 354 were mostly disbursed for crop production. 355 Potential borrowers were not required to pro- 356 vide collateral security but they had to provide 357 evidence that they were full-time farmers, were 358 resident in the village in which they had their 359 farm, and two guarantors who should be per- 360 sons of good standing in the community. The 361 second scheme, specifically intended for live- 362 stock development, was the smallholder cattle- 363 fattening and work-oxen loan scheme. Loans 364 could be used either to fatten mature cattle over 365 a six-month period, or to purchase pairs of 366 work-oxen, complementary equipment and 367 other related inputs over a period of three 368 years. Borrowers were required to procure all 369 inputs, which were usually given in kind, from 370 the National Livestock Projects Division, a 371 government agency. As with other NACB loans 372 intended for smallholder producers, borrowers 373 were not required to provide collateral security, 374 rather they had to provide two guarantors who 375 had to be persons of good standing and proven 376 character in the community. NACB charged 377 15% and 17% nominal interest rates on its beef- 378 fattening and work-oxen loans, respectively. 4 379 These rates were below the 25% lending rate 380 charged by commercial banks for similar ac- 381

tivities. In real terms interest on NACB loans 383 for beef fattening and work-oxen were -20.5%384 and -19.1%, respectively (Gefu, 1992).

A common feature of the credit programs was an elaborate process for screening applicants involving third parties to do the screening or to vouch for the applicant. Attending to these processes involved high transaction costs for applicants for small amounts of credit. The smaller credits had proportionately higher transaction costs.

(b) Purpose of livestock loans

Analyses of the purposes for which loans were given were based on data on UCB loans disbursed in 1992, AIDB loans disbursed during 1985-89 and NACB loans disbursed in 1988/89. Of all the livestock loans given by UCB in Uganda, 48% were given to purchase animals (15% for purchasing purebred exotic breeds and 33% for purchasing crossbreeds), 22% for development of infrastructure, e.g., fencing and water development, 14% for animal health inputs, and 16% for purchase of feeds and other inputs. The use of loan funds usually depended on the type of animals farmers kept, herd size and the size of grazing area. For example, farmers keeping up to 10 crossbred cows spent 11% of loan funds on animal health; those with the same number of purebred exotic cows spent almost double that amount on animal health. This suggests that the adoption of purebred exotic cows with higher milk productivity potential was more dependent on credit than more robust crossbred herd operations.

In Ethiopia, 46% of livestock loans disbursed by AIDB were given for dairy enterprises including milk-processing activities by state farms, 22% for beef fattening, 21% for animal traction, 10% for feed processing and 1% for dairy goats. The aggregate nature of the data did not permit clear distinction of smallholders from other categories of borrowers. AIDB staff suggested however, that smallholders were given loans mainly to finance animal traction and beef fattening while state farms were given loans primarily for dairy operations. About 78% of loans disbursed by NGOs were for the purchase of oxen, 22% for beef-fattening enterprises, and less than 0.5% for dairy enter-

In Nigeria, of the livestock loans disbursed by NACB 82% were given for beef fattening (purchase of cattle, supplementary feeds, veterinary drugs, and construction of barns), 8% 436 for sheep fattening, 9% for poultry rearing, and 437 438 1% for animal traction.

(c) Beneficiaries of livestock loans

In Uganda, only 13% of the total number of 440 livestock loans disbursed went to smallholders 441 with less than five hectares of cultivable land, 442 17% to owners of 5–10 hectares, 23% to owners 443 of 10-20 hectares, 34% to owners of 20-50 444 hectares and 13% to owners of over 50 hectares. 445 Average loan size was US\$290 per borrower. 5 446 There were, however, large variation in loan 447 size depending on the location of the borrower 448 and the purpose of the loan. At branches near 449 major urban centers such as Kampala, loans 450 tended to be larger, averaging between US\$359 451 and US\$431 while average loan size for rural 452 bank branches ranged between US\$232 and 453 US\$314. A major reason for this disparity in 454 loan size was that borrowers close to urban 455 areas, such as Kampala, tended to purchase 456 more purebred exotic animals than rural bor- 457 rowers. These were more expensive than 458 crossbred cows and they required larger outlays 459 for veterinary care and feed.

In Ethiopia, farms are generally small due to 461 the egalitarian distribution of land by the pre- 462 vious government, and the small number of 463 livestock loan recipients other than the state 464 farms could be classified as smallholder live- 465 stock producers. Detailed data collected from 466 three sample areas where AIDB operated 467 showed that average farm size of borrowers 468 ranged between 2.6 and 4.7 hectares while av- 469 erage herd size was between five and six cattle. 470 Average loan size ranged between US\$290 and 471 US\$580 for dairy loans, US\$242 and US\$611 472 for oxen loans, and US\$169 for beef-fattening 473

In Nigeria, three sample areas in the north of 475 the country where NACB operated, the mean 476 farm sizes of loan beneficiaries ranged between 477 two and eight hectares while average herd size 478 ranged between three and 16 cattle. The cattle- 479 fattening loan was US\$289 for first time bor- 480 rowers with the amount rising to US\$867 for 481 borrowers with a proven credit worthiness 482 rating. The maximum loan for work bulls or 483 equipment was US\$867.

(d) Duration and repayment of livestock loans

The banks in Uganda and Nigeria tended to 486 provide short-term loans to individuals and 487

organized groups while the bank in Ethiopia mostly provided long-term loans. The majority of loans given by UCB in Uganda were for a fixed 18-month term regardless of the purpose of the loan. Repayment started after six months and the borrower was expected to pay the loan in full within the fixed term. In Ethiopia, loans for beef fattening were given for five years with the borrowers required to make one repayment per year. Dairy loans were given for five years. Repayment started after one year with equal annual repayments for the next four years. Oxen loans were given for four years with one repayment required in each year. In Nigeria, NACB loans for beef-fattening operations were given for a period of six months, to be repaid in one lump sum at the end of the period.

In Uganda, the average recovery rate of livestock loans was 66%. In Ethiopia, AIDB could not provide up-to-date records on livestock loan recovery rates. But, aggregate loan recovery performance of the bank was poor. For example, as of June 1993, 89% of total outstanding loans were in arrears (Tilahun, 1994). Moreover, rates of defaults appeared to be increasing due, in part, to the dissolution of the service and producer cooperatives. In the absence of enforcement mechanisms, most cooperatives were dissolved without repaying their loans. In Nigeria, NACB reported steadily increasing loan recovery rates since the inception of the smallholder direct loan scheme. When the scheme started in 1988, loan recovery rate was at a dismal 2%. By 1992, average loan recovery rate had increased to 87% although there were wide variations in recovery rates by state and branches. This steady improvement in NACB's loan recovery was partially due to its rigid loan collection policies, which denied further loans to defaulters. In cases of noncompliance the guarantors were compelled to repay the loans. Borrowers with prompt repayment record were encouraged to re-apply for larger loans.

4. DAIRY TECHNOLOGY ADOPTION AND DEMAND FOR CREDIT

(a) Technology adoption

The farm surveys in Ethiopia, Kenya and Uganda revealed that the sample farmers in all three countries used one or more components of four broad categories of improved dairy technology, i.e., genetics, health, nutrition, and

management. The genetics component included 540 the purchase of crossbred or purebred exotic 541 animals and use of artificial insemination. The 542 health component included the use of veteri- 543 nary drugs and services. The nutritional component included the use of improved fodder 545 and concentrate feeds. The management component included improved husbandry practices 547 such as barn construction or training related to 548 improved technologies.

In Ethiopia, all the sample farmers had 550 crossbred cows while in Kenya and Uganda 551 some farmers had only crossbred cows and 552 some others had both crossbred and purebred 553 exotic cows. In all three countries, nearly all 554 farmers also kept indigenous cows for milk 555 production as well as traction. In Ethiopia, all 556 the sample farmers used grass hay as the prin- 557 cipal forage supplement followed by green oats 558 (92%) and, oats and vetch hay (28%). In Kenya, 559 Napier grass was the principal forage for all the 560 farmers while in Uganda Napier grass (89%), 561 banana peelings (84%) and potato vines (77%) 562 were the principal forage supplements. In 563 Ethiopia Noug cake and oat seed were the most 564 common concentrates used by 44% and 59% of 565 the sample; in Kenya dairy meal (98%) and in 566 some case maize bran and brewers grain and in 567 Uganda dairy meal (82%), maize bran (40%) 568 and cottonseed cake or sunflower cake (8%) 569 were the principal concentrates. Two-thirds of 570 the Kenya sample but none in Ethiopia prac- 571 tised zero grazing. There was no information 572 on this for Uganda (Freeman et al., 1998).

(b) Incidence of borrowing and liquidity constraint

Forty-nine percent of the sample farmers in 576 Ethiopia borrowed varying amounts for dairy 577 activities compared to 40% in Kenya and 79% 578 in Uganda. The survey revealed that some 579 nonborrowers already had sufficient realizable 580 capital while some borrowers and some non- 581 borrowers had liquidity problem but did not 582 have access to credit at all or could not get 583 enough for the intended purposes. This sug- 584 gested that it was not adequate to classify 585 farmers as merely borrowers or nonborrowers. 586 A more subtle classification system was needed 587 to determine why some smallholder dairy pro- 588 ducers used credit and others did not and they 589 were further classified as liquidity-constrained, 590 i.e., in need of more funds or liquidity-non- 591 constrained, i.e., having access to sufficient 592

funds to meet their immediate investment aspirations.

A farmer was classified liquidity-constrained if (i) he/she already had a loan but expressed a wish to borrow more at the current interest rate; or (ii) he/she was unable to obtain a loan because the request for a loan was turned down, or there was no access to formal or informal lenders, or no dairy animals were 602 available for purchase within their means. ⁵ In Ethiopia, 35% of the sample farmers—31% of borrowers and 38% of nonborrowers—were liquidity-constrained; in Kenya 29% of the sample—58% of borrowers and 9% of nonborrowers—were liquidity-constrained, and in Uganda 55% of the sample—61% of borrowers and 35% of nonborrowers were liquidity-constrained.

The credits were primarily used to purchase crossbred or purebred exotic cows. Some farmers used a small portion of the credit to purchase improved feeds, veterinary inputs or to construct barns and water supply systems for their dairy animals. Nonborrowers, when purchased these items, used their own funds. Generally the level of input use was marginally higher for borrowers and liquidity-nonconstrained farmers compared to nonborrowers and liquidity-constrained farmers, though only in a few cases such differences were statistically significant (Table 1). Therefore, generally all farms lost opportunities to benefit from the milk yield potential of the improved cows due to shortage of cash to buy inputs (Freeman et al., 1998).

(c) The determinants of being a borrower and being liquidity constraint

Since some borrowers borrowed though they did not have liquidity constraint while some borrowers and some nonborrowers did not have access to adequate credit, an attempt was made to determine the factors influencing borrowing vs nonborrowing and liquidity-constrained vs liquidity-nonconstrained status of farms. Logistic regression was applied using borrowing status and liquidity status as binary dependent variables: borrower = 1, nonborrower = 0; liquidity-nonconstrained = 1, liquidity-constrained = 0. The coefficients of the equations were estimated using SPSS Logistic Regression procedure (Norusis, 1993). The variables included in the best-fit models and related hypotheses are defined below.

Table 1. Input use per animal by borrowing and liquidity status of farms in Ethiopia, Kenya and Uganda^a

^a Forage and concentrate: kg/animal/day; vet expenses: US\$/animal/year.

Site: a dummy variable for sample sites in each country: out of two sites one takes the value 1, the other 0. There are some differences between sites within a country with respect to, e.g., breeds of dairy animals used, availability of feeds, so it was hypothesized that such differences might influence borrowing and liquidity status of the sample farms.

Gender: a dummy variable for gender of household 653 head where male = 1, female = 0. In Ethiopia, only 4%of the sample household heads were female compared to 27% in Kenya and 32% in Uganda. It was hypothesized that female-headed households had less access to formal credit than male-headed households. Education: a dummy variable for the education status 659 of the household head where no formal education = 0, primary or above = 1. In Ethiopia, 34% of the household heads had primary or higher-level education compared to 86% in Kenya and 94% in Uganda. Agricultural technology adoption is often found to be influenced by education and credit (Feder & Umali, 1993), so it was hypothesized that better educated households had more access to credit and had less liquidity problem.

Training: a dummy variable for attendance at special 669 training or workshop on dairy cattle or livestock management by a household member, where no attendance = 0, attendance = 1. In Ethiopia, 28% of the sample farmers had attended special training compared to 34% in Kenya and 77% in Uganda. In Ethiopia and Uganda, NGOs involved in dairy development projects and in Kenya the Ministry of Agriculture provided such training. Following earlier findings of Thirtle and Ruttan (1987) and Feder and

^a Marked factors had significant influence on borrowing status.

Umali (1993), it was hypothesized that special training

680 may influence demand for credit through adoption of 681 improved technologies requiring higher investment. 682 Outstanding loan: a dummy variable for outstanding 683 loan where no outstanding loan = 0 and having out-684 standing loan = 1. Having outstanding loan may pre-685 clude having another loan but in some cases, a higher 686 amount may be given to repay existing loan. In 687 Ethiopia, none of the sample farmers reported having 688 any outstanding loan except the current one (this 689 could be an underreporting given that the supply side 690 analysis indicated that there were many defaulter co-691 operatives, hence individual farmers); in Kenya 87% 692 of borrowers and 5% of nonborrowers had at least 693 one outstanding loan at the time of the survey, and in 694 Uganda all the borrowers and 54% of nonborrowers

699 and liquidity status. Age: age of household head in years. It was hypoth-701 esized that age could serve as a proxy for experience, 702 and more experienced farmers would be more likely to 703 borrow to adopt new technology.

had at least one outstanding loan at the time of the

survey. The outstanding loans were not necessarily

obtained for dairy. It was hypothesized that out-

standing loan had a negative influence on borrowing

Farm size: farm size in acres. In Ethiopia, the previous government distributed cropland to households according to the size of the household, so farm size was excluded from the Ethiopia model.

Herd size: herd size in tropical livestock units (TLU). The following conversion rates were used to arrive at TLU: adult females, bulls, oxen = 1, steers 1-2years = 0.80, heifers 1-2 years = 0.75, calves 6months-1 year = 0.40, calves under 6 months = 0.20, sheep, goats = 0.10 (ILCA, 1993). Average herd size in Ethiopia, Kenya and Uganda was, respectively, 35.1, 6.0 and 5.1 TLUs.

716 Crossbred cow equivalents (CBCE): the sample farms 717 held crossbred and/or purebred exotic and/or local 718 Zebu cows. Therefore it was not possible to specify 719 number of each breed of cows as independent variables nor could they be simply added into one variable by assuming all cows as equivalent to one TLU, because cows of different breeds had different feed requirements and milk yield potentials. In the absence of information on actual body weight and/or feed intake, all cows on a farm were converted into crossbred cow equivalents by using the sample average milk yield ratios as weights. For example, if average lactation yields of purebred exotic, crossbred and local cows in a country sample were in the ratio of 1:0.7:0.3, these ratios were used to convert all cows in that country sample into CBCEs. In Ethiopia, Kenya and Uganda, average number CBCE was, respectively, 2.43, 2.86 and 1.94.

In 749 Uganda, the odds of a farmer being a borrower 750 was significantly higher if it was located in the 751 district near Kampala and was male-headed, 752 the farmer had attended special dairy training 753 course/workshop, had at least one outstanding 754 loan, and marginally higher with larger number 755 of CBCEs, and significantly lower if the farmer 756

^a Marked factors had significant influence on liquidity status.

had higher education. The negative effect of a larger number of CBCEs on the probability of borrowing in Ethiopia and Kenya might be explained by the fact that these loans were provided mainly to acquire improved cattle stock, so those who already had good number of such cows would not qualify for new loans but those having none or few might qualify.

The regression results for liquidity status are shown in Table 3. In Ethiopia, the odds of a farmer being liquidity-nonconstrained was significantly higher if the farmer was located in Selale area, had larger number of CBCEs (implying that larger number of improved cows might generate adequate cash income to reduce the need for borrowing to meet cash needs), and significantly lower if the farmer had attended special dairy training. In Kenya, the odds of a farmer being liquidity-nonconstrained was significantly higher if located in Limaru district, had higher education, marginally higher with larger herd size and significantly lower if the farmer was female, attended special dairy training/workshop and had outstanding loans (i.e., having more loans implies more outflows in repayments, so less possibility of being liquidity-nonconstrained). In Uganda, the odds of a farmer being liquidity-nonconstrained was marginally lower for femaleheaded households, significantly lower if the farmer had attended dairy training, significantly higher if the farmer had higher education and outstanding loan (this was an opposite situation compared to Kenya).

5. SUMMARY OF FINDINGS AND IMPLICATIONS FOR DESIGNING NEW CREDIT SCHEMES

(a) Summary of findings

All the banks in the three countries had a 795 common official objective of increasing the flow 796 of institutional credit to large numbers of 797 smallholder livestock producers. To meet this 798 objective, they had established specialized sub- 799 sidized credit schemes and had opened bran- 800 ches in rural areas. Despite these mechanisms, 801 this study revealed that few smallholder live- 802 stock producers actually got credit from formal 803 sources. Often, smallholder producers were 804 screened out by the criteria for loan eligibility. 805 For example, UCB in Uganda required poten- 806 tial borrowers to show evidence that the ap- 807 plicant owned livestock infrastructures, which 808 was partly what they wanted the loan for. In 809 Ethiopia, credit was allocated on political, 810 rather than financial considerations, and it was 811 given on concessionary terms to state farms and 812 cooperatives despite their poor performance 813 and high levels of loan delinquency. Since this 814 took up most of the funds there was little left 815 for the many smallholder producers who were, 816 therefore, denied credit. In Nigeria and 817 Uganda, the banks did not insist on collateral 818 security. They usually based creditworthiness 819 on the personal characteristics of potential 820 borrowers. In cases where bank officials did not 821 have sufficient information on a potential bor- 822 rower they tended to allocate credit on ob- 823 servable characteristics such as wealth or 824

WORLD DEVELOPMENT

influence in the community. These factors screened out many potential smallholder borrowers who did not appear creditworthy or about whom they did not have complete information.

Because the credit was subsidized, demand tended to exceed supply and the available funds had to be rationed. The rationing rules often favored influential community members who, for the most part, got larger loans. Since the amount of the subsidy increased in proportion to the amount of the loan these policies aggravated the income inequalities between small and large borrowers.

In Uganda and Nigeria, most of the loans were short-term with fixed repayment periods. AIDB in Ethiopia was the only institution to have the majority of its portfolio in long-term loans with more flexible repayment periods. The other banks may have opted for short-term loans because of the need to collect loans quickly, especially under conditions of high inflation and controlled interest rates, which rapidly erode the real value of loan repayments. Another reason for short-term loans might have been that borrowers did not have assets to offer as collateral.

There is, a priori, no ideal loan term. It is important to maintain the flexibility to relate loan terms to factors such as the uses to which it will be put, the cash flow generated by the funded activity, and the attendant risks. When these factors are not taken into account the consequences are likely to be inefficiencies in the use of loan funds and increased incentives to default. This occurred in Uganda where under UCB's conditions on short-term loans borrowers were not able to generate sufficient revenues to repay their loans, within the stipulated periods, from the proceeds of the funded investments. In Nigeria, the short-term loans given by NACB for beef fattening were much shorter than the average fattening period of between 12 and 18 months. This limited borrowing to customers who had alternative means of financing repayments and effectively excluded those who had most need for credit.

On the other hand, in Ethiopia, where most livestock loans ranged from 4 to 5 years, bank officials' lax attitude toward recovery and low level of supervision contributed to poor loan recovery even though revenues were generated by funded activities sooner than the permitted repayment period. In an attempt to encourage repayments the Service Cooperatives were given financial incentives, in addition to threats

of denial of fresh loans in case of default by 881 some of their members. Apparently these 882 measures were also not effective because the 883 option of denying the service cooperatives fresh 884 loans because of outstanding repayments was 885 not actually exercised. The records show that 886 fresh loans were never denied for this reason 887 and political motives, which promoted cooperatives irrespective of their performance, also 889 contributed to low levels of loan recovery (Ti- 890 lahun, 1994). The poor rate of loan recovery led 891 to failure of the credit programs.

In Nigeria, NACB's 85% recovery rate sug-893 gested that its mandatory collection policy, 894 which denied future loans to defaulters, was 895 effective. But, the bias toward relatively large 896 borrowers contributed to high rates of loan 897 recovery because these producers have the fi-898 nancial means and appreciated the high value 899 of NACB's subsidized credit line (Aku, 1986).

The UCB in Uganda reported recovery rates 901 of 66% on livestock loans in 1990. This was 902 partly attributed to the fact that loan repay-903 ments were consistent with the regular cash 904 flow of dairy activities. The farmers were paid 905 weekly or bi-weekly by the dairy corporations, 906 which are the major buyers and distributors of 907 fresh milk in Uganda.

An important aspect of improving the supply 909 of credit to rural clients is the development of 910 true financial intermediaries that facilitate sav- 911 ings mobilizations and credit distribution (De- 912) sai & Mellor, 1993). But, the credit institutions 913 examined in this study did not mobilize savings. 914 They all relied completely on the government 915 and foreign donors for loanable funds. In 916 Ethiopia and Nigeria this was a result of de- 917 liberate government policy, which prohibited 918 mobilizing savings from the public. In addition, 919 these institutions only distributed credit and 920 did not provide any banking services to their 921 clients. Thus, they could not be regarded as true 922 financial intermediaries. They did not recognize 923 the links between demand for and supply of 924 funds nor did they exploit the complementa- 925 rities between investment in new technologies 926 and increased liquidity.

These findings are consistent with the find- 928 ings of related studies in the crop sector. With 929 few exceptions, formal credit programs in sub- 930 Saharan Africa have performed rather poorly. 931 Despite substantial outlays, credit subsidies 932 have led to misallocation of resources, have 933 typically not led to significant increases in 934 adoption of new technologies, and have not 935 succeeded in replacing traditional money lend- 936

ers (Adams, 1995; Braverman & Guasch, 1986; Krause *et al.*, 1990; Olomola, 1994; Von Pischke, Adams & Donald; World Bank, 1994).

The surveys of the demand for credit for dairy activities revealed that smallholder farmers in Ethiopia, Kenya and Uganda were prepared to borrow from formal credit institutions as well as use their own funds to purchase crossbred and/or purebred exotic dairy cows. Some farmers used small amounts of their loans to build barns, water supply systems or purchase feeds and veterinary care. In all three countries, there were farms among both borrowers and nonborrowers who did not have sufficient funds to expand or improve their dairy enterprises. This made it necessary, in addition to classifying farms as borrowers and nonborrowers, to also classify them according to their liquidity status in which credit could be a component. Regression analysis showed significant differences between the profiles of borrowers vs nonborrowers and between liquidity-constrained and liquidity-nonconstrained farms in all three countries. Sex of household head, education, dairy training, prevalence of outstanding loan and the number of improved cattle on the farm had significant influence on both borrowing and liquidity status, though the degree and direction of influence were not always the same in each country. Contrary to the findings of the supply side analysis, farm size and herd size had neutral effects on borrowing in all three countries, which probably could be explained by the fact that this was based on a sample focusing only dairy farmers.

Borrowers used their loans mainly to acquire improved cows, so the primary impact of credit was to increase milk production through increased dairy herd size. Borrowers and nonborrowers alike spent very little on better feed and management. This is not a tenable longterm solution because smallholders cannot readily expand their crop and grazing land areas. Thus greater emphasis must be given to increasing milk production through better feeding and management. Assuming that cash constraints were the primary reason for inadequate spending on inputs there is great potenfor increasing milk production reinforcing loans for acquiring cows with working capital loans to ensure proper feeding and management.

These findings from supply and demand side analysis suggest that, public credit institutions

do not have sufficient funds to meet the de- 993 mand for credit and cannot mobilize savings 994 from their clients or other commercial sources 995 for one reason or another, and available credit 996 does not reach those who need it the most and 997 with whom it could have the greatest impact. 998 To become more effective and sustainable, 999 credit institutions that intend to serve small- 1000 holders need to rationalize their screening 1001 procedures and the criteria they use to deter- 1002 mine creditworthiness. To reach poor and li- 1003 quidity-constrained smallholders the credit 1004 must also be provided at a cost they can afford 1005 while the system remains viable. That includes 1006 interest charges and transaction costs and for 1007 small amounts of money the latter becomes 1008 most critical. Lower interest rates would en- 1009 courage innovation but they must be consistent 1010 with the cost of capital, the risk of default and 1011 servicing costs. To be effective and encourage 1012 repayments, the amount of the loans and their 1013 repayment terms must be matched to the in- 1014 come generating and cash flow patterns of the 1015 investments for which the loan are given. That 1016 means they must square any subsidy on interest 1017 rates with the potential contribution of the 1018 credit to overall output growth and economic 1019 development. To be sustainable, credit systems 1020 need to be able to attract savings to provide 1021 1022 capital for future lending.

(b) Implications for designing new credit schemes

Recognizing the need to involve commercial 1025 banks to increase credit supply, governments in 1026 some countries have tried to use legislation to 1027 force them to increase the proportion of agri- 1028 cultural lending in their portfolios. But this was 1029 not successful because it is contrary to banking 1030 norms, so some other way must be found. 1031 Nominal interest rates have been found to be 1032 less important than intuitively assumed in de- 1033 termining demand for credit (Henk Moll, per- 1034 sonal communication). In order to engage the 1035 poorest farmers however, the interest that they 1036 are charged should at least not be more than 1037 that charged to their commercial large-scale 1038 competitors. This conundrum can be resolved 1039 by leveraging high-interest commercial money 1040 with low-interest government funds. To illus- 1041 trate this assume that government (G) wants 1042 smallholders to have access to inputs at say 1043 16.5% per annum despite the fact that com- 1044 mercial banks (B) are charging 20% per annum. 1045 This could be achieved through an appropriate 1046

mix of government (either from own sources or 1048 from foreign loan or aid) and commercial fi-1049 nance as illustrated below:

1050 -If (B) commits its own \$3 million at 20% in-1051 terest, it would expect to earn \$600,000 per an-1052 num. The interest rate comprised of say 10% 1053 cost of capital, 5% cost of servicing (transac-1054 tions cost) and 5% coverage for default (risk). 1055 —If (G) lends \$3 million to (B) at 3% per an-1056 num, (B) would owe (G) \$90,000 per annum 1057 but would still be responsible for recovering 1058 servicing cost and risk, for which the bank 1059 would need to charge an additional 10% to 1060 earn an additional \$300,000.

1061 -Then (B) would need to recover \$990,000 by 1062 investing \$6 million, and could do so by 1063 charging 16.5%. This would make more funds 1064 available to more people at lower cost. 1065

As noted above however, the interest rate on capital is not always the main component of the cost of credit to the borrower. On small loans the transaction costs are usually more serious than the interest charges because the time and paperwork does not decrease proportionately. They are much higher per unit of credit than for large borrowers, especially those who deal directly with their suppliers or bank managers. This is the reason why even large-scale farmers prefer supplier credit and overdrafts to loans with lower interest charges. Feed mills and other farm input suppliers in developed countries and in agriculturally developed sectors in developing countries have their own source of inventory finance that enables them to provide goods on credit. A classic illustration of this was the interdependence between European farmers and Indian shopkeepers in pre-independent Kenya. The Central Bank of Uganda and Barclays also initiated a similar scheme in the early 1970s but political disruption did not permit its full implementation.

To provide smallholders with the same possibility of being able to take goods on credit village suppliers including livestock breeders, farmers' supply stores and veterinarians may be provided with inventory finance tied to the inputs required by the smallholders. Without such support they will necessarily continue to focus their businesses on more profitable fast 1096 turnover goods such a beer and cigarettes. But, with tied inventory finance they would become very efficient credit providers because, through their long-term relationships with their customers, they can assess creditworthiness in- 1100 stantly on the spot. They also become 1101 motivated extension agents because the only 1102 way they can make a profit is to move the 1103 goods off their shelves.

Enabling smallholders to purchase goods in 1105 the form, amounts and locations of their choice 1106 would encourage them to innovate and get 1107 optimum production from their smallholdings 1108 and livestock. But these are not the character- 1109 istics of the prevailing credit schemes. For ex- 1110 ample, in Kenya smallholder dairy producers 1111 can only get credit if they sell milk through a 1112 cooperative even if it does not offer the best 1113 price. To make matters worse, they get credit 1114 only when they have milk to deliver and have 1115 good records of delivery, which means that they 1116 cannot buy feed for steaming up cows prior to 1117 parturition and, therefore, can never hope to 1118 reach the full production potential of their cows 1119 (Steve Staal, personal communication).

By providing larger inventory finance loans 1121 to relatively few easily reached creditworthy 1122 village suppliers, rather than small loans to 1123 thousands of small producers, the commercial 1124 banks would be able to spared the unusually 1125 high servicing costs associated with rural credit. 1126 The finance would only be available for agreed 1127 inputs in noncommercial quantities that are not 1128 otherwise readily available in rural areas. To 1129 ensure that the funds reach the intended bene- 1130 ficiaries, the amount provided by the govern- 1131 ment would be proportional reimbursement of 1132 the amounts advanced by the commercial bank. 1133

If the provision of inventory finance for rural 1134 suppliers of goods and services is effective in 1135 encouraging smallholders to take up innova- 1136 tions, a second phase could be developed to 1137 encourage savings. If the scheme is successful, it 1138 would provide a solution to the long running 1139 difficulty of engaging commercial banks in ru- 1140 ral finance. It would also provide governments 1141 and development agencies such as the World 1142 Bank and IFAD with an exceptional instru- 1143 ment for influencing the cost of credit to 1144 smallholders without meddling in the com- 1145 mercial decisions of participating banks. 1146
