Bans versus Fees:
Disposable Carryout Bag Policies and Bag Usage

Bans versus Fees: Disposable Carryout Bag Policies and Bag Usage

Abstract *Using observational data on consumer carryout bag usage, we measure the effects of Disposable Bag Policies on bag demand. Our results show that plastic bag bans with paper bag fees eliminate use of disposable plastic bags and increase use of reusable bags. However, we find significant and undesired increases in paper bag demand. We compare our results to a study on bag fees and conclude the types of bags stores choose to sell in lieu of disposable plastic bags, as well as the price of alternatives, impact whether bans are more successful than fees in discouraging disposable bag demand. JEL code: H23, Q58.*

Disposable carryout plastic bags bring convenience to supermarket customers, but at a substantial cost to the environment and to municipalities trying to keep their streets and waterways clean. With plastic bag clean-up, recycling, and land-filling costing cities and local governments millions of dollars per year, Disposable Bag Policies are gaining popularity among lawmakers across the country. Disposable Bag Policies prohibit retail stores from providing customers with free carryout bags at checkout. The ultimate goal of these policies is to alter consumer behavior—curbing the consumption of single-use bags and encouraging the use of reusable bags. Yet, while all Disposable Bag Policies share this common goal, in practice they differ in their policy prescriptions, dividing into two competing approaches: (1) Bag bans—a command-and-control approach to regulate behavior directly and (2) Bag fees—a market-based approach to incentivize individuals to change their own behavior.

The adoption of both types of policies has been widespread in the U.S. At the local level, fees on both plastic and paper carryout bags have been adopted by several cities and counties on the east coast, while the most popular policy prescription on the west coast has been bans on plastic bags coupled with fees on paper bags. At the state level, as of October 2014 legislation stood with two states having already banned plastic bags,¹ three states considering similar bans,²

¹ California and Hawaii (all four counties in Hawaii have banned plastic bags making it a statewide ban in effect).

and four states considering fees on all disposable bags.³ In light of the pervasiveness of both policies, this paper asks: *Does the type of policy matters with respect to changing consumer behavior?*

The standard economic analysis, dating back to Pigou's work in the 1920's, has emphasized the efficiency advantages of economic incentive (EI) mechanisms, such as fees and taxes, over command-and-control (CAC) approaches, such as bans (Sandmo 1976). When polluters (i.e. plastic bag users) differ in their costs of abatement (i.e. forgoing plastic carryout bags), the flexibility offered by EI approaches reduces the aggregate cost of achieving a given level of pollution reduction in comparison to uniformly-applied CAC policies. However, the cost of information and monitoring also underlie the choice between taxes and bans. Compliance with bans may be relatively cheaper to monitor, which could account for the occurrence of these forms of regulation (Christiansen and Smith 2012). Moreover, when there is significant uncertainty about the costs of pollution abatement, the outcomes from regulations which set a pollution quantity (or cap) can differ from those which set a pollution price, and conditions for one to dominate depend on the sensitivity of marginal abatement costs and marginal pollution damages to the pollution level (Weitzman 1974). Therefore, if policymakers do not know consumers' demand elasticity for disposable carryout bags or the pollution damages from an additional bag, economic theory is ambiguous about whether bans or taxes should be chosen.

Given the theoretical uncertainty and the growing prevalence of both types of policies, it is imperative to compare outcomes under each regulation tool. With this objective in mind, we (1) empirically investigate whether a bag ban has had its intended effects on the types of bags consumers use at checkout, and (2) compare and contrast outcomes under this bag ban to those

² Massachusetts, New Jersey, Rhode Island, and Puerto Rico.

³ Massachusetts, New Jersey, New York, and Pennsylvania.

of a bag fee. To accomplish the first task, we take advantage of a policy change in the neighboring Californian cities of El Cerrito, Richmond, and San Pablo. Starting January 1, 2014, these cities began to prohibit retail stores from providing customers with plastic single-use bags at checkout. Any retail establishment that provides a recycled paper carryout bag or reusable bag to a customer must charge a minimum of five cents per bag. Using this policy change as a natural experiment, we collect observational data on customers' bag choices at a set of stores in these cities, both before and after the policy took effect. We observe customers during checkout and record the number and types of bags used, the length of transaction times, whether a bagger was present and basic customer demographic information. Besides collecting counterfactual data in the pre-policy period, we also collect data at stores in the control cities of Berkeley and Concord, where there was no bag policy change during our sample period.

With our unique panel dataset, we use a simple difference-in-differences empirical strategy to measure how plastic bag bans with paper bag fees affect customers' demand for various types of disposable and reusable bags. We further measure whether changes in consumer behavior due to the policy shock are heterogeneous across the size of the fee (i.e. 5-cent fees versus 10-cent fees) and store type (i.e. national supermarket chain versus discount chain). In particular, we collect data at two markedly different grocery chains within the same treated and control cities. Not only do these chains attract a different clientele within the same city—as evidenced by the demographic data we collect—their management also chose different responses to the same Disposable Bag Policy. The first chain, which we refer to as the National Chain, chose to charge the minimum required 5 cents per paper bag. Alternatively, the second chain—referred to as the Discount Chain—chose to charge 10 cents per paper bag and introduced a 15-cent thick-plastic reusable bag. By running the same difference-in-differences analysis on each

of these chains separately, we are able to compare how the types and prices of bags offered influence consumer behavior.

For our second objective, we investigate how outcomes under plastic bag bans compare to outcomes under bag fees, by juxtaposing our results to those of a concurrent bag fee. Homonoff (2013) studies the 5-cent single-use plastic and paper bag fee in Montgomery County Maryland and finds that the use of disposable bags drops 42 percentage points after the policy implementation. While there exist previous studies examining how Disposable Bag Policies affect consumer behavior (Dikgang et al. 2012), Homonoff (2013) was the first to collect data on bag usage in both the pre- and post-policy period and at treated and control stores. By replicating the methodology of Homonoff (2013) on our sample of stores, we are able to directly compare results, and consequently, draw conclusions on the effectiveness of bag bans versus bag fees.

To preview some of our results, we find that both policies lead to remarkably similar increases in reusable bag usage and reductions in disposable bag usage at National Chain stores.⁴ However, in comparing the Discount Chain to the National Chain, we find that charging 10 cents (instead of 5 cents) for paper bags and offering cheap, alternative reusable bags leads to even larger reductions in disposable bag demand. Specifically, after the policy change, paper bag demand increased by only 8.52 percentage points at Discount Chain stores, as compared to 46.50 percentage points at National Chain stores. Thus the types of bags that stores decide to sell in lieu of single-use plastic bags, as well as the price of alternatives, has significant impacts on the effectiveness of Disposable Bag Policies, especially in regards to paper bag demand.

To our knowledge, no other study has empirically compared the effect of these two types of policies on bag demand; however, empirical evidence for other commodities does exist. With

⁴ We refer to both paper and plastic bags as disposable bags. Thus for customers facing a plastic bag ban, disposable bag use is only comprised of paper bags. For customers facing a paper and plastic bag fee, it is a mix of both.

respect to the regulation of production-side externalities, empirical studies have compared EI instruments versus CAC approaches in reducing air pollutants (Oates et al. 1989) and in incentivizing the production of higher fuel economy vehicles (Greene 1990). However, given that the *consumption* of disposable bags creates the externality in question, our analysis relates more closely to the limited empirical literature on the regulation of consumption-driven externalities. For instance, Adda and Cornaglia (2010) analyze the effect of bans and taxes on passive smoking and find that excise taxes are more effective at reducing exposure to tobacco smoke than smoking bans in public places. The reason is that bans displace smokers to private places where they contaminate non-smokers, especially young children. Although disposable bags and cigarettes are very different commodities in many respects, our analysis likewise finds that bans displace consumption in unintended ways in which taxes do not.

As the first study to both rigorously analyze consumer bag demand responses to plastic bag bans with paper bag fees and to compare outcomes under bag bans to those under bag fees, the results of this paper have the potential to shape current and future policy—and not just policies regulating disposable bags but also other disposable products such as Styrofoam containers and plastic bottles. Our results suggest that as cities, counties, and states continue to design and adopt Disposable Bag Policies, they will want to consider not only their objectives for reusable and plastic bag usage, but also their objectives for paper bag consumption. The rest of the paper proceeds as follows. Section 2 reviews the background on disposable carryout bags. Section 3 describes the empirical setting, the policy changes that led to the experimental design, the data collection methodology, and the data. Section 4 lays out the empirical strategy and presents the results. Section 5 compares our results to previous studies and discusses policy implications and Section 6 concludes.

Background on Disposable Bag Policies

Environmental Costs of Disposable Carryout Bags

Standard disposable plastic bags cost retailers on average 3 cents each and paper bags cost 7 to 10 cents each.⁵ However, customers do not directly see the price of the disposable bags they use, as the majority of grocery stores roll the price of these bags into the total cost of the transaction. Without seeing a price, customers are prone to use more plastic bags than they would be willing to pay for at face-value, and this overuse is costing municipalities millions in clean-up expenses annually. Each year Americans are estimated to consume 100 billion single-use plastic bags (Clapp and Swanston 2009)—approximately 325 bags per person per year—the vast majority of which are eventually landfilled or littered. When not kept in landfills, plastic bags end up in storm drains, rivers and oceans—degrading water quality, harming birds and aquatic life, clogging waterways, and becoming a general eyesore. Even when properly disposed of in a receptacle, plastic bags are easily blown away due to their light weight and aerodynamics (Kauffman & Wolff 2009). Furthermore, the 5.2 percent of plastic bags that do get recycled (USEPA 2006) become a major problem for recyclers as the bags often clog the machines used to sort material.⁶ A study of the budgets of 6 major cities in the U.S. finds that the litter control of plastic bags costs between 3.2 and 7.9 cents per bag (Burnett 2013). Given that approximately 100 billion plastic bags are consumed in the U.S. each year, municipalities across the U.S. together spend up to \$3.2 to \$7.9 billion per year to clean-up plastic bags.

In light of the sizeable costs of plastic bags, one might be tempted to answer the age-old

⁵ Bag cost estimates come from interviews with the store managers in our sample, but media articles also confirm these estimates (“Plastic Ban Means Higher Costs are in the Bag.” *Crain’s Chicago Business*. 3 May 2014. [Online](#)). The cost of paper bags depend on bag size and the presence of handles. Store owners list disposable bags as their fourth largest operating cost, after electricity, payroll, and credit card fees.

⁶ “Which Bag is Best: Paper or Plastic?” *The Oregonian*. 17 May 2007. [Online](#).

question “Paper or Plastic?” with a resounding “Paper!” However, single-use paper bags are not without their own environmental costs and thus may not be an adequate alternative to plastic. The negative environmental impacts of paper bags include: (i) paper bags are more energy and water intensive to manufacture than plastic bags, with paper bag production using 70 percent more energy and 17 times more water than the production of plastic bags of the same carrying capacity (Chaffee and Yaros 2007), (ii) it takes 98 percent less energy to recycle a pound of plastic than a pound of paper, and (iii) paper bags are 9 times heavier than plastic bags and require more space in transportation trucks and landfills.⁷ Therefore, by switching from plastic to paper, society is simply trading one set of environmental costs for another. However, the important take-away is that the environmental costs of single-use plastic bags are felt acutely in the budgets of local municipalities, especially those along waterways, whereas the environmental cost associated with paper bags are more broadly spread across all people in a population. Therefore it is unsurprising that in practice Disposable Bag Policies have been more aggressive against plastic bag consumption than paper bag consumption.

Policies to Regulate Disposable Carryout Bags

Given the aforementioned costs of disposable bag usage, governments in the U.S. began passing laws to regulate disposable bags in the mid to late 2000’s.⁸ On January 1, 2010 the District of Columbia became the first city in the U.S. to require a fee, charged at checkout, for using single-use plastic and paper bags. This law—which passed in response to a District

⁷ “Graphic: Paper or Plastic?” *The Washington Post*. Oct. 3, 2007. [Online](#).

⁸ Internationally disposable bag regulations started earlier, with several countries banning the use of plastic bags in the global South, where the externalities of plastic bags are exacerbated by less established municipal waste collection and recycling. Policies later spread to the global North, with Ireland becoming the first industrialized country to impose a tax on customers for using plastic bags in 2002 (Convery et al. 2007).

Department of Environment study that found plastic bags comprised 47 percent of trash in D.C.'s rivers and tributaries (DDOE 2008)—had the joint goals of changing consumer consumption of bags and raising revenue for watershed clean-up. Several counties surrounding D.C. have since followed suit with similar laws. Although the fee magnitude has varied across municipalities (between 5 and 25 cents), in general retailers get to keep a portion of the fee to cover the cost of implementation, while the municipality may keep any remaining cents to be used for funding clean-up and recycling programs.

Unlike many of their east coast counterparts, Californian cities and counties have passed plastic bag bans with paper bag fees instead of requiring fees for both. In California the charges for paper bags are kept completely by the retailers and none of the revenue is collected by the local government implementing the law. Why has California chosen bans over fees? The answer lies in California Assembly Bill 2449. This bill, enacted in 2006, began as a plastic bag fee bill but—due to pressure from the plastic bag manufacturing industry—transformed into a plastic bag recycling bill. Moreover, a last minute change to this law prohibits “a city, county or other public agency from adopting, implementing, or enforcing an ordinance, resolution, regulation or rule that imposes a plastic carryout bag fee upon a store.” Consequently, plastic bag fees have not been an available policy option for those California municipalities that did not feel recycling programs went far enough in addressing their disposable bag problems.⁹

San Francisco was one such city. In 2007 San Francisco enacted a citywide ban on single-use plastic bags, becoming the first government in the U.S. to do so. This sparked the spread of Disposable Bag Policy adoption in California, with the cities of Malibu and Palo Alto adopting similar laws in 2008 and 2009 and Los Angeles County passing even stronger

⁹ “The Plastic Bag Ban Epic.” *LA Observed*. Sep. 6, 2014. [Online](#).

legislation in the summer of 2011—not only banning plastic bags but also charging a minimum of ten cents per paper bag. By the time the Richmond bag ban—the primary policy in our analysis—went into effect in 2014, over 55 city and county bans had been implemented in California.¹⁰ While, the requirements of CA Bill 2449 were only operative until January 1, 2013 and any bills passed in California in and after 2013 could technically choose bag fees over bag bans, interestingly none of the ordinances passed in 2013 or 2014 opted for a plastic bag fee.

Yet plastic bag fees are not completely out of the picture. In 2013 two bills were introduced in the California Senate—one of them a plastic bag ban with paper bag fee and the other a fee on both plastic and paper bags.¹¹ Furthermore, several supermarket chains in areas affected by plastic bag bans have found a way to satisfy customers willing to pay for plastic bags—selling 15-cent thick-plastic reusable bags at checkout. These bags meet all the requirements of current Californian Disposable Bag Policies: they are at least 2.25 mils thick, they are capable of carrying 22 pounds for 125 uses, they have handles and are made from materials that can be cleaned or disinfected, they are made from 20% recycled materials and are recyclable themselves. The main issues with the current single-use plastic bags are that they are “free”—leading them to be excessively overused—and lightweight—making them difficult to landfill and recycle. Selling a bag that is neither free nor lightweight solves both of these issues, while also providing utility to customers willing to pay for them.¹²

However, some view these 15-cent bags as a loophole for stores and manufacturers to get

¹⁰ Another 50 local bag bans were adopted by the time the statewide ban was signed into law in September 2014.

¹¹ Senate Bill 270—the bill signed into law—bans single-use plastic carryout bags statewide and requires stores to sell paper and reusable bags for at least 10 cents each. Senate Bill 700—which died in committee—would have instead required stores to charge 5 cents for both plastic and paper single-use carryout bag.

¹² Senate Bill 270 also provides \$2 million in grant money from a California recycling fund to assist plastic bag-making businesses in producing these types of reusable bags.

around the intention of the plastic bag bans. Skeptical on whether 15-cent thick-plastic bags are in fact reused, a handful of municipalities are considering upping their reusable bag requirement to 3 mils thick to prevent the use of these bags. Therefore, not only do governments considering Disposable Bag Policies have to decide between bag bans versus bag fees, they must also decide on the types and thickness of reusable plastic bags to allow. Our paper addresses both policy debates, first, by comparing consumer demand outcomes under bag bans to those under bag fees, and second, by examining the various types of bags consumers reuse—whether they are standard reusable totes bags, paper bags, backpack, boxes, or alternative 15-cent reusable bags.

Data Collection and Summary Statistics

To assess the effectiveness of single-use plastic bag bans, we take advantage of a policy change in the neighboring Californian cities of El Cerrito, Richmond, and San Pablo. Starting January 1, 2014, these cities began to prohibit retail stores from providing customers with plastic single-use bags at checkout. Any retail establishment that provides a recycled paper carryout bag or reusable bag to a customer must charge the customer a minimum of five cents for each bag provided, a fee that goes entirely to the retailer collecting it. Using this policy change as a natural experiment, we collect observational data on customers' bag choices at a set of grocery stores, including three treated stores located in the cities of El Cerrito, Richmond, and San Pablo, two control stores in the city of Berkeley (where a Disposable Bag Policy had already been imposed a year prior to the new policies), and two controls stores in the city of Concord (where no Disposable Bag Policy has been enacted). Since the city of Richmond geographically envelopes the cities of San Pablo and El Cerrito, we group all three cities together as one region (Richmond) for the remainder of this paper.

The data were obtained through direct observation of transactions by members of our research team stationed near checkout lanes. For each transaction we collected data on the number and types of bags used, whether a bagger is present, the length of the transaction and basic demographic data such as gender and race of the person paying.¹³ This type of transaction specific information can only be gained from in-store observations, and is not included in the scanner datasets from these stores. Four visits per store occurred in November and December 2013, before the Richmond Disposable Bag Policy went into effect, and 4-6 visits occurred in January and February 2014, after the ban was in place. We also made an additional 4 visits in March and April 2014 to collect follow-up data. Each visit lasted 1-2 hours and was made on either Saturday or Sunday between 11am-7pm—high foot-traffic hours for grocery shopping.¹⁴

We visit a total of seven stores belonging to two different categories of grocery chains within the same treated and control cities. The first retail chain is a large National Chain, offering high and low prices in many products, located in very diverse demographic regions, and that, in the pre-period, offered to its consumers at checkout free plastic bags, free paper bags, and reusable tote bags for purchase of \$1.50. The other chain we collect data from is a regional Discount Chain, which in the pre-period offered only free single-use plastic bags and reusable tote bags for purchase of \$0.99. Not only do these two chains offer different types of bags in the pre-period, their managements also respond differently to the same policy change. The National

¹³ Our methodology for data collection is based on that of Homonoff (2013) in that we collect data by direct observation at treated and control stores in the pre- and post-policy period. However, while Homonoff (2013) collected data on bag usage in broad categories (disposable bags versus reusable bags), we go further and collect data on the sub-categories of bags used. Sub-categories of disposable bags include: single-use plastic and single-use paper. Sub-categories of reusable bags include: reusable tote bags, 15-cent thick-plastic bags, reused disposable paper and plastic bags, backpacks, purses, boxes, suitcases, and other. Another difference is that we collect data on the presence of baggers, which may influence the number and types of bags customers use.

¹⁴ To prevent potential biases, we randomized the order in which we visited the stores on each observation date.

Chain reacts to the ban by continuing to offer the same paper and reusable tote bags as before the policy, but adds the required 5-cent fee per paper bag. Alternatively, the Discount Chain retains the reusable tote bag it sold before the ban but additionally introduces a 10-cent paper bag and a 15-cent thick-plastic reusable bag.¹⁵ Not only does the National Chain opt to charge the minimum amount for paper bags required by law, its paper bags are of a slightly better quality than the Discount Chain, whose paper bags do not have handles. Table 1 reports background information on the seven stores in our sample—three from the National Chain and four from the Discount Chain—including when the policy went into effect at each store, what stores charge for paper bags in the post-policy period, the number of transactions we observe at each store, and pre-ban store characteristics (average number of lanes open, percent of transactions with baggers present, and average length of transaction times in seconds).¹⁶

At the National Chain, the policy change implies an infinite price on plastic, a five cent price on paper, and the usual price on reusable tote bags available. In this case we can see how consumers react to the differential relative price changes of the bag options available to them. At the Discount Chain, we instead measure how consumers suddenly adjust behavior to new bag alternatives that have a positive price as compared to the free plastic option. Moreover, by measuring the effects on consumer behavior in the Discount Chain separately from the National Chain, we are able to focus on what we hypothesize to be a very price sensitive population.¹⁷

¹⁵ The price of the reusable tote bags does not change after the policy implementation at either chain. While the Discount Chain sells \$0.99 reusable totes before and after the ban, our team never witness a purchase of these bags.

¹⁶ More observations were made at National Chain stores on average over the sample period because data collection occurred at the National Chain stores on two dates more than at the Discount stores. Also, since the Richmond area has two locations of the Discount Chain, we decide to make observations at both in order to increase our total number of observations and statistical power.

¹⁷ While we cannot measure the income of customers in our sample, based on our conversations with managers and anecdotal evidence at the Discount Chain stores, we conjecture that Discount Chain stores have a higher proportion

Figure 1 (a) and (b) plot the percentage of transactions using each of five types of bags—(i) thin single-use plastic, (ii) brought reusable bags, (iii) bought during checkout reusable bags, (iv) paper bags, and (v) no bags—for the National Chain and for the Discount stores respectively. The summary statistics are separated into the three policy regions—(1) Concord: control stores with no ban ever, (2) Richmond: treated stores with a policy change, and (3) Berkeley: control stores with a ban pre-dating the sample period. Each of these cases is further examined in two time periods: the PRE-ban period = Nov-Dec 2013 and the POST-ban period = Jan-Feb 2014. In Figure 1, we see stark changes in the distribution of the type of bags used that are contemporaneous with the bag policies across the treatment and control groups. The first thing to note is that only the treated Richmond stores see a noticeable change in bag usage between the PRE and POST period. Second, while the Richmond stores have similar bag use distributions to their Concord counterparts in the PRE period, they switch to a distribution more similar to that of their Berkeley counterparts in the POST period. The take-away of these graphs is that stores in cities with plastic bag bans and paper bag fees see a higher use of reusable bags and paper bags, a higher incidence of customers using no bags at all, and a complete eradication of newly-issued disposable plastic bags.

We also examine how the distributions of bag use vary across store type, for stores with bans and for stores without. At both the National and Discount Chain stores, nearly 100% of transactions use some sort of bag when there is no bag policy in place. Conversely, only ~85% of transactions at National Chain stores use a bag when there is a bag policy, and only ~70% do likewise at Discount Chain stores. In regards to reusable bags, between 30% and 50% of transactions bring reusable bags to stores that have bag policies in effect. This is true for both

of low income customers and SNAP and WIC participants than the National Chain.

chains. In terms of purchasing bags, at National Chain stores with bans, roughly 40% of transactions pay the 5 cents per paper bag with handles and only 1% pay \$1.50 for a reusable tote bag. At Discount stores, only 30% of transactions pay for bags at checkout, with approximately 10% paying 10-cents for paper and 20% paying 15-cents for thick-plastic reusable bags. Interestingly, the 15-cent bag is more popular than the 10-cent paper bag at Discount stores. This preliminary surveillance of the raw data suggests that plastic bag bans cause a large increase in paper bag demand; however, this increase in paper demand may be mitigated if customers are charged more for paper bags or offered a cheap and desirable alternative.

Next we use the pre-treatment period data to investigate whether the pre-period is balanced in terms of observable determinants, such as customer demographics and bag usage within and across chains. Since we employ a difference-in-difference strategy, a critical assumption is the appropriate selection of the treatment and control groups. Our selection rules for the control and treatment cities were (i) the presence of both retail chains within the city, (ii) proximity—only cities within one hour travel of the research team, (iii) accessibility by public transit, and (iv) most importantly, the two control cities matched Richmond in terms of average demographics characteristics, based on available census data. To verify whether the control and treatment cities are well matched, table 2 presents demographic and income summary statistics from the pre-period. Reported in the top panel are 2012 census data for the proportion of each city’s population that is male, white, black, as well as the total population and the average salary in each city. Richmond has a larger proportion of minority residents than either Berkeley or Concord, but in terms of average salary, Richmond looks very similar to Concord. To understand whether our selected stores are representative of the entire city, the middle and bottom panel present the summary statistics of the observational data collected for the proportion of customers

that were male, white, and black at the National and Discount stores respectively. Compared to the census data, the clientele of the National Chain stores appear to be fairly representative of the cities in which they live. On the other hand, the percentage of black and minority clientele at the Discount stores are 10-20 percentage points greater than representative of the census data, and this true across all cities. We feel this is strong evidence that the National and Discount chains attract a very different clientele, even within the same city.

The other critical identification assumption is that of parallel trends—where, had it not been for the Disposable Bag Policies, Richmond would have had the same change in bag usage over time as Berkeley and Concord. To validate this assumption, we again plot bag usage for each treatment group and store chain, but this time over each observation date. These plots illustrate that bag usage is stable at each store before the policy goes into effect.¹⁸ In regards to other observable characteristics, the last three columns of table 1 show that, in the pre-period, National Chain stores have baggers present for between 50-65% of transactions, approximately 4.6 registers open at a time, and transaction times ranging from 86-93 seconds. Conversely, the Discount Chain stores have baggers present less frequently (8 to 56% of transaction), fewer registers open (2.3 to 3.4 registers), and a wider variance of average transaction times (76-96 seconds). Overall, the sample averages for these variables compared within each chain are similar, suggesting that the treatment and control stores share broadly equivalent patterns in the pre-period.¹⁹

¹⁸ Since these plots reiterate the information from figure 1 in many ways, we present them in the online appendix.

¹⁹ The Berkeley Discount store appears to be an outlier across these 3 measures in the pre-period. This is partly because the Berkeley store already had a bag policy during the pre-period and partly due to the layout of the checkout lanes at the Berkeley store, which has very little standing room for baggers.

Difference-in-Differences Empirical Strategy and Results

We use a regression framework to evaluate the effect of the Richmond bag ban on measures of bag demand controlling for various individual- and store-level covariates. We consider two measures of bag demand for each type of bag: demand on the *extensive margin* (the percent of customers using each type of bag) and demand on the *intensive margin* (how many bags each customer uses given they use a particular type of bag). We exploit the quasi-experimental panel design to perform a difference-in-differences econometric estimation strategy. The reduced form specification is:

$$Y_{st}^B = \beta_0 + \beta_1(Richmond * Post)_{st} + \alpha_s + \beta_3 Post_t + \gamma X_{st} + \varepsilon_{st},$$

where Y_{st}^B is a measure of demand on either the extensive or the intensive margin in store s during year t for type of bag $B = \{\text{plastic, paper, bought reusable, brought reusable, no bag}\}$, $Richmond_s$ is an indicator for observations at stores in Richmond, $Post_t$ is an indicator for observations in 2014, which are after the implementation of the policy, α_s represents store fixed effects, and X_{st} is a set of controls in store s during year t . The coefficient of interest is β_1 , that is, the coefficient on the interaction of $Richmond_s$ and $Post_t$, which measures the effect of the ban on demand in treated stores relative to changes in demand in control stores. We estimate the above specification for each chain and bag type separately.

Tables 3 & 4 present the results—from the National and Discount Chain respectively—for the effects of the Richmond bag ban on bag demand for the various types of bags, along both the extensive and intensive margins. To estimate demand on the extensive margin, we use a linear probability model where the outcome variable is the probability of using a particular type of bag.²⁰ To estimate demand on the intensive margin, we use OLS where the outcome variable

²⁰ We found that a probit model produces similar results.

is the total number of bags used among those that use them. Each specification includes—in addition to the interaction of the Richmond*POST indicators, the POST indicator, and store fixed effects—fixed effects for the date of visit, hour of visit, week-in-month of visit (first, second, third, fourth), and observer. We include these fixed effects since the profile of the average grocery shopper is not constant over the course of a day, day of the week, or week in the month.²¹ We also control for whether the transactions occurred in an express lane, whether a bagger was present for at least part of the transaction, whether the customer paying was male, and whether the customer paying was white. These controls are added to further prevent differences across locations and time periods from biasing the results. Lastly, we cluster the standard errors at the store-day level to account for the possibility that the errors are correlated within a given store on a particular day, but not across stores or dates.

In table 3 we find that, in regards to the extensive margin, the ban at National Chain stores led to a decrease in plastic bag consumption of 81.57 percentage points, an increase in paper bag use of 46.50 percentage points, an increase in bringing reusable bags of 26.03 percentage points and an increase in buying reusable bags of 4.24 percentage points. In addition, the percent of customers using no bags increased by 9.25 percentage points. With respect to the intensive margin, in column 6 we see that the bag ban caused the number of paper bags used per transaction by paper bag users to decrease by 2.29 bags. Thus even though National Chain customers use paper bags 46.50 percentage points more often after the policy change (extensive

²¹ Studies have shown that as the day progresses, the average age of grocery shoppers' declines, while their incomes rise (Goodman 2008). If we don't include these time fixed effects, and age and income are correlated with using reusable bags over disposable bags, differences in the timing of observations across locations could bias our results. Another way in which customers' profiles are not constant over time is that SNAP and WIC participants are more likely to use their benefits in the first weeks of the month. According the Food and Nutrition Service of the USDA (2012), 80 percent of SNAP benefits are used within the first 2 weeks of issuance. In addition, according to Goodman (2008), shoppers on Sundays are noticeably younger than those on other days of the week.

margin), those who use paper bags use fewer paper bags per trip (intensive margin). In column 7 we find that the average number of reusable bags brought by reusable bag users at the National Chain did not increase by a statistically significant amount due to the ban.

Table 4 present the results for the Discount Chain, where the imposition of the ban led to a decrease in disposable plastic bag use of 89.99 percentage points, an increase in paper bag use of only 8.52 percentage points, an increase in bringing reusable bags of 18.97 percentage points and an increase in buying 15-cent reusable bags of 28.74 percentage points. The probability that customers use no bags increases by 31.20 percentage points. On the intensive margin, column 6 shows that the average number of reusable bags used by reusable bag users at Discount stores per shopping trip increased by 0.513 bags after the policy change

Comparing the Discount and National Chain results, we find that at both chains (1) the presence of a bagger is correlated with an increase in the probability in customers using disposable bags and a decrease in the probability of customers using no bags,²² (2) male customers are less likely to bring reusable bags and more likely to use no bags than female customers, and (3) white customers are more likely to bring bags than customers of other races. When contrasting the Discount Chain and the National Chain, it is interesting to note that the increase in paper bag usage is more than 5 times larger at National Chain stores than at Discount stores. Also, Discount store customers are 3 times more likely to use no bags than National Chain store customers. Finally, customers at Discount stores choose to buy 15-cent reusable bags more often than 10-cent paper bags. We suggest that this difference occurs for several reasons: (1) the National Chain stores sell paper bags for 5-cents less than the Discount stores, (2) Discount stores sell an alternative reusable bag for \$0.15 as opposed to the National Chain, who

²² Baggers are instructed to keep busy and float to checkout lanes where there are groceries to bag. Thus the correlation between bag use and baggers may be due to baggers moving to larger transaction that need bags.

only sell \$1.50 reusable tote bags, and (3) Discount Chain shoppers may be more price sensitive than National Chain shoppers.²³

Bag Bans Versus Bag Fees and Policy Implications

If the objective of Disposable Bag Policies is to increase the use of reusable bags and decrease the use of disposable bags, how do bag bans and bag fees compare in reaching this objective? To answer this question we compare the proportion of customers using reusable bags and disposable bags in Homonoff's (2013) sample to the proportion of customers using reusable and disposable bags in our sample. As mentioned above, Homonoff studied the 2012 Montgomery County Maryland Disposable Bag Policy which imposed a 5-cent fee on both disposable plastic and paper bags. In Homonoff's study, stores in Virginia were without a Disposable Bag Policy and thus are comparable to our Concord store. Stores in Washington, DC had a 5-cent bag fee for two years when the Montgomery County Maryland Disposable Bag Policy went into effect and thus are comparable to the Berkeley stores in our sample. Lastly, the Maryland stores are the ones treated in Homonoff's study and thus are comparable to the Richmond stores in our sample. Note that while Maryland and Richmond customers face very different prices for thin plastic bags (5 cents versus infinity) both face the same magnitude of fee

²³ Using the additional data collected in March and April, we also examine at how and whether bag demand changes over time, as customers grow accustomed to Disposable Bag Policies. This analysis—presented in the online appendix—shows that at the National Chain the probability of bringing reusable bags decreases by almost 10 percentage points and the probability of using no bag increases by 10 percentage points over time. We believe these changes occur because customers learn that they can repack their cart item by item without bags and then bring the cart out to their vehicle (where they may or may not have bags) to unload it again. Conversely, at the Discount Chain, the probability that shoppers bring a reusable bag increases 7 percentage points over time and the probability of buying a 15-cent reusable bag decreases by 5 percentage points. We hypothesize that this change occurs in part because a fraction of customers begin reusing the 15-cent bags they purchased previously.

for paper bags (5 cents).

We first focus on the National Chain stores in our study since they are more comparable to the grocery chains used by Homonoff (2013).²⁴ The darkly shaded bars in Figure 2 (a) plot the proportion of customers bringing reusable bags and (b) the proportion of customers using disposable bags (either thin plastic or paper) at National Chain stores across policy jurisdictions and treatment periods. In panel (a) we see that bag bans and fees have very similar effects on encouraging customers to bring reusable bags—with ~46% of customers facing a ban and ~47% of customers facing a fee choosing to bring reusable bags. In panel (b) disposable bag usage is also similar under both types of policies, though on average the proportion of bag ban customers using disposable bags is 6 percentage points less than the proportion of bag fee customers. In summary, at National Chain stores bans and fees have similar effects on reusable bag usage, while bans lead to slightly less disposable bag usage than fees. Yet what is not shown here is that disposable bag use for ban customers is completely comprised of paper whereas for fee customers it is a mix of paper and thin plastic.²⁵ Since paper bags have their own set of environmental costs, policymakers and citizens may be concerned by the significant increase in paper bag usage under plastic bag bans.

However paper is not the only alternative type of bag that grocery stores can offer. The 15-cent thick-plastic bags are an alternative to thin plastic bags and they do not have as large of side-effects of being easily blown around or clogging recycling equipment. This begs the

²⁴ We also drop all January observations so that our POST period is more similar to that used by Homonoff (2013), whose data in the pre-period was collected from late September to early November of 2011 while data in the post-period was collected from late February to early March of 2012.

²⁵ Homonoff (2013) does not decompose disposable bag usage into paper and plastic because “almost all customers chose to use plastic bags when they were offered.” Looking at our pre-period data, we also find that the vast majority of customers chose plastic bags over paper bags when given the option.

question: How does the proportion of customers using reusable and disposable bags under a bag ban with the 15-cent thick-plastic bag option compare to bag usage under policies without this alternative? To answer this question, we compare bag usage at our Discount stores to both those at our National Chain stores and those in Homonoff's sample.²⁶ Focusing now on the lighter shaded bars, in panel (a) we see that having an alternative type of bag to buy doesn't significantly alter the proportion of customers bringing reusable bags. In other words, reusable bag usage is stable across Disposable Bag Policies and store types. However, in panel (b), we find that the presence of an alternative bag to purchase has a large effect on the proportion of customers using disposable bags. Only 10 percent of customers at Discount stores with bans use disposable paper bags, compared to roughly 40 percent of customers at stores without 15-cent thick-plastic bags. Therefore 15-cent thick-plastic bags seem like desirable alternatives to thin plastic bags, especially for those who worry that bag bans lead to an increase in paper bag consumption.

In light of concerns that the thick-plastic bags are not actually reused by customers, our unique experimental design allows us not only to measure the number of customers buying the thick plastic bags, but also the number reusing them as well. At Discount Chain stores with a bag ban in place, forty-one percent of customers brought at least one reusable bag. Of those customers bringing reusable bags, 18 percent brought the 15-cent reusable bag. In comparison, only 6 percent of customers bringing reusable bags to the store brought old paper bags. Moreover, we find that 2 out of 5 customers that buy 15-cent bags reuse them in future purchases. Therefore, a large percentage of Discount Chain customers do reuse the 15-cent thick-plastic bag for future purchases. And this is just a lower bound for the reuse of these bags, which

²⁶ When making this comparison, we want to keep in mind the caveat that the clientele at Discount stores is very different than at National Chain stores.

may be reused in other ways by customers (e.g. bag liners for small garbage bins).

Given these results, our main policy recommendation for municipalities considering Disposable Bag Policies is that retailers should be required to make the price of all types of bag they offer transparent to their customers at purchase. Just by having a salient price, much of the externality of the overuse of disposable bags is eliminated. Second, for cities and counties and states that opt for plastic bag bans with paper bag fees, we recommend incentivizing the production and sales of 15-cent thick-plastic reusable bags. The thickness of these bags makes them less likely to blow out of garbage systems and into water-ways. Plus they are both recyclable and reusable. Furthermore, we find that when Discount stores offer their price-sensitive customers 15-cent bags after the imposition of a plastic bag ban, they produce similar levels of reusable bag usage and smaller levels of paper bag usage than at National Chain stores without these bags.

Conclusion

This is the first study to empirically compare the effect of bans versus fees on consumer bag demand. We use observationally recorded bag usage data (over bag type, time, and space) to measure shifts in bag demand in response to the introduction of a ban on plastic bags with a fee on paper bags. Our results suggest that this type of policy—while completely eliminating disposable plastic bag consumption and increasing reusable bag usage—leads to significant increases in paper bag demand. At the National Chain, the percent of customers using paper bags climbs from 5% before the policy to over 40% afterwards; however, the fee for paper bags is effective in that those who choose to buy paper use fewer paper bags per transaction after the policy change. In contrast, the percent of customers using paper only increases to 10% at

Discount stores. Second, we compare bag demand outcomes under plastic bag bans (with paper bag fees) to those under bag fees alone and find that both reach the same objective of increasing reusable bag usage. Moreover, bans and fees have similar effects in terms of reducing disposable bag consumption, that is, unless stores offer inexpensive reusable bags and charge more for paper bags, in which case bans may be more effective than fees. Consequently, if the environmental costs of increased paper bag usage are a concern to policymakers and the public, these results suggest that Disposable Bag Policies should also consider the types and prices of bags that stores choose to sell in lieu of disposable plastic bags.

These results are not only relevant for the regulation of disposable bags, but can also inform policies regulating other disposable products, such as Styrofoam containers and plastic bottles. Future work will focus on other unintended effects of Disposable Bag Policies. We aim to merge our observational bag usage data with corresponding transaction-level scanner data to measure whether bag policies lead to changes in the composition of shopping baskets and in the time necessary for checkout. While bag bans and bag fees were found to be similar in their effects on reusable bag usage in this study, they may differ along other dimensions, such as their effects on store productivity and consumer purchases.
