Price Volatility and Spillovers in Food and Fuel Markets

Henry An, Feng Qiu and James Rude

Motivation

- In recent years, prices of agricultural commodities have experienced major spikes and greater volatility.
- The growth of the biofuels market has led many researchers to examine the relationship between food and biofuel prices.
- Evidence suggests that there is a closer relationship between food and fuel prices, which can be attributed to U.S. biofuel policy.
- However, there have been comparatively few studies that have examined the extent to which volatility is transmitted across different price markets.
- In addition, no study as far as we know has investigated the effect of a binding blend wall on nature of the relationship.
- Our objective is to characterize the nature of price volatility spillovers between the corn, crude oil and ethanol markets across a time period that includes both a non-binding and binding blend mandate.

Results I

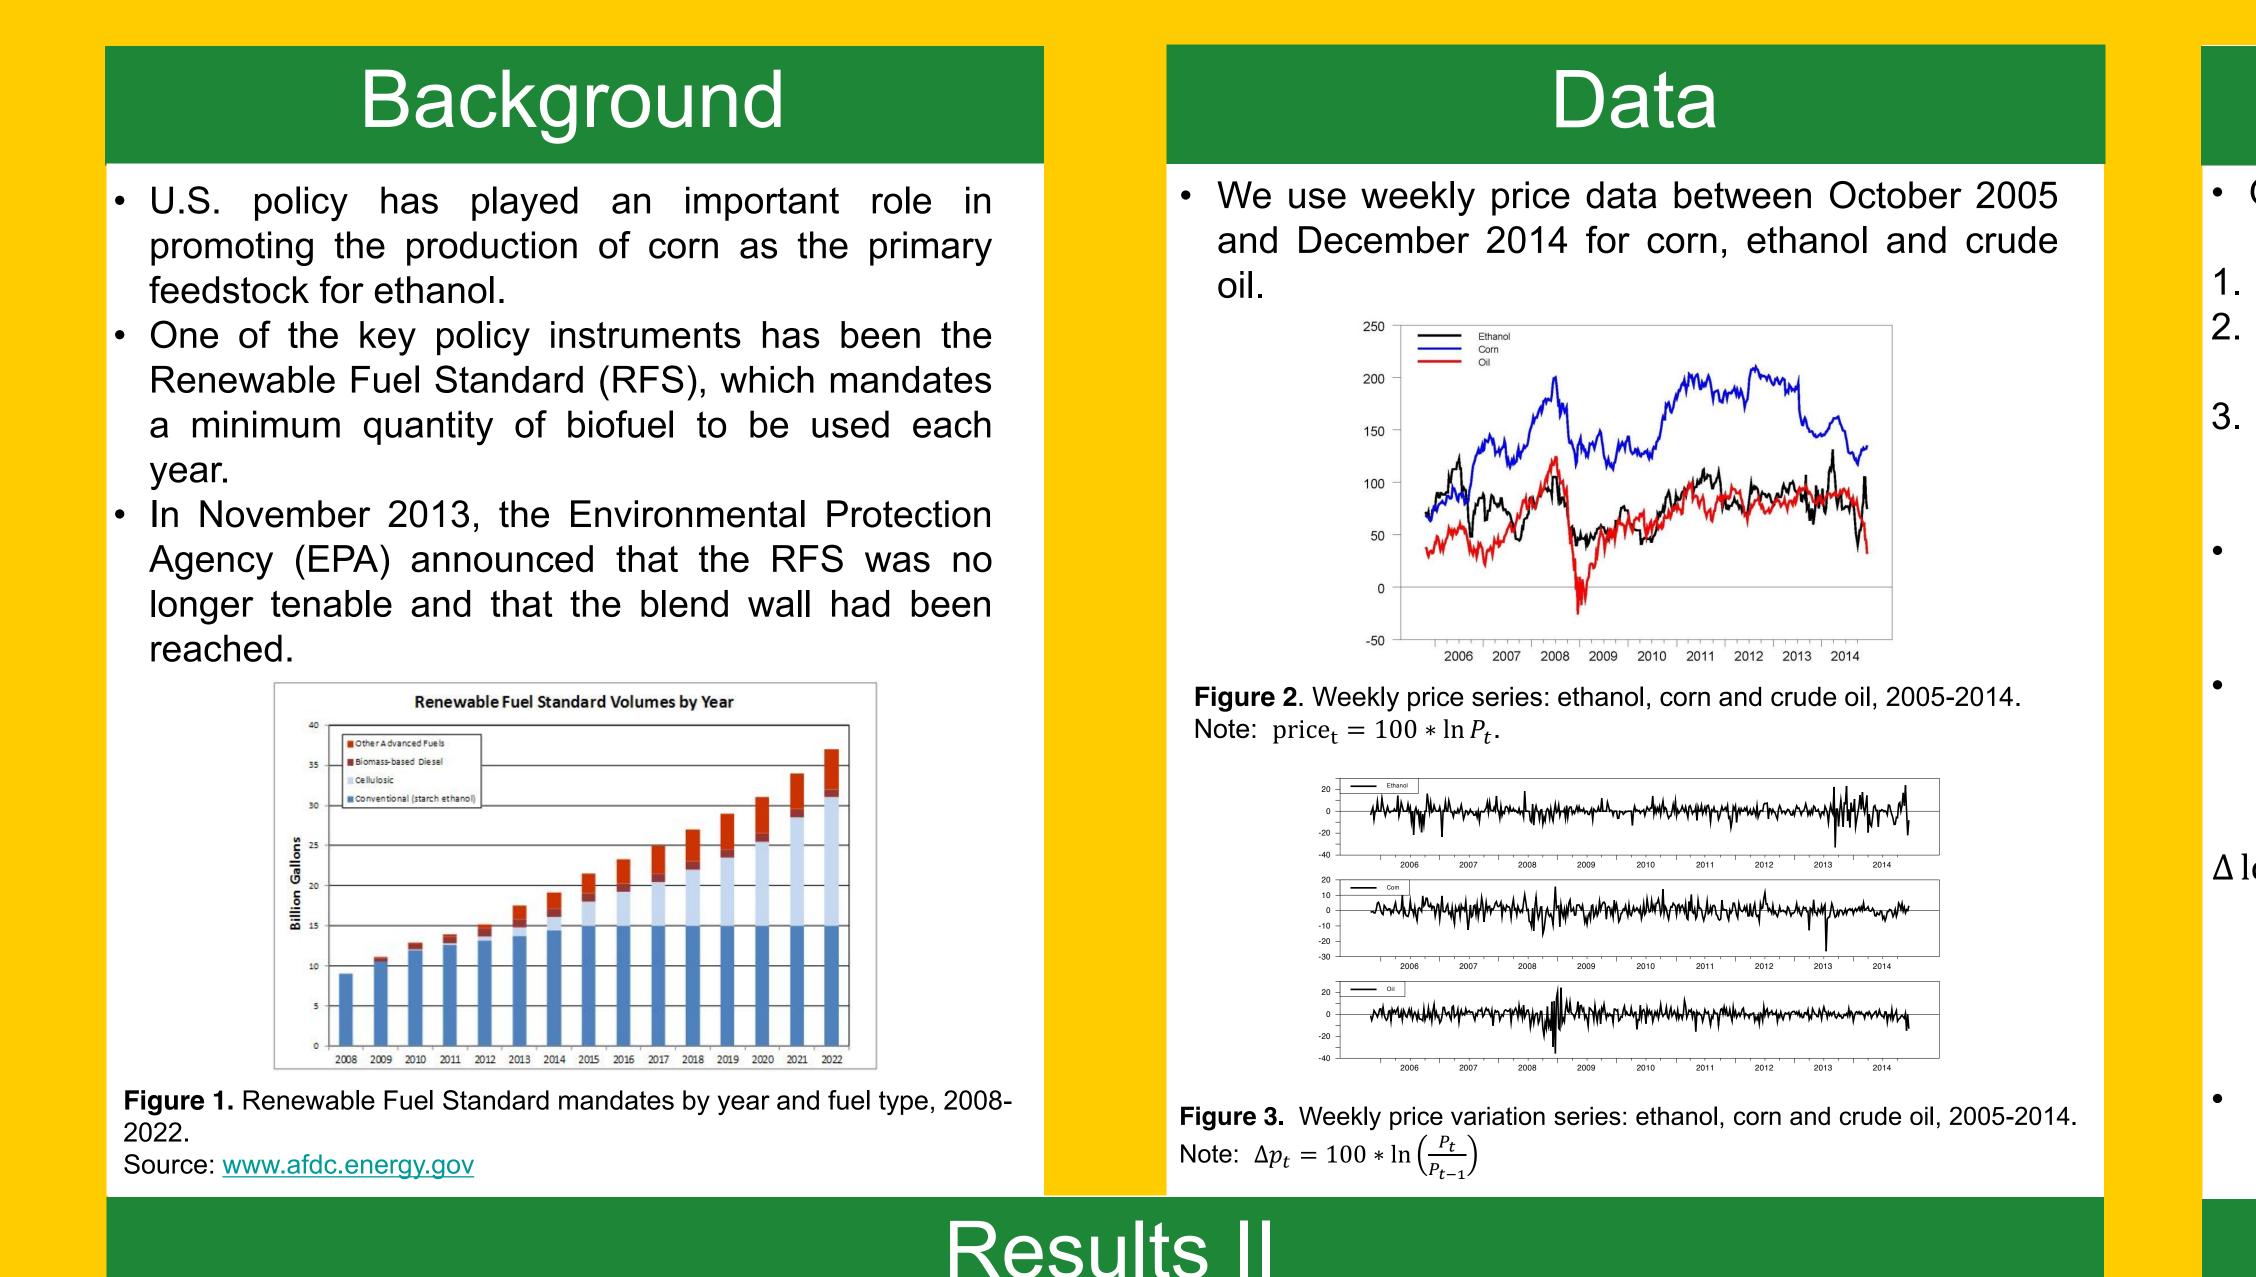

Cointegration results

- Only ethanol and crude oil prices are cointegrated.
- Ethanol price responds to the error correction term but crude oil price does not, which suggests that ethanol price follows the crude oil market but not vice versa.
- Ethanol and crude oil prices respond to corn prices.

Volatility for single markets

- Volatility persistency *B*(i,i): ethanol and oil are both very high and corn is relatively low.
- Vulnerability to market shocks A(i,i): ethanol is relatively high, other two are low.
- Asymmetric effects (i.e., impacts of negative market shocks on volatility C(i,i)): All three have large asymmetric effects. Corn C(2,2) oil C(3,3)ethanol C(1,1).

Department of Resource Economics & Environmental Sociology, University of Alberta

Market interdependency (dynamic correlations)

- Ethanol & corn: Strong in 2008/09, relatively constant from 2009 – mid 2013, and drop to zero since mid 2013.
- Ethanol & oil: Strong in 2009, and relatively weak other than that period.
- Corn & oil: Strong between 2008/09, drop to about zero since 2013.

Spillover results

- Ethanol \rightarrow corn : none
- Ethanol \rightarrow crude oil: none
- Corn \rightarrow ethanol: previous corn volatility affects current ethanol volatility
- Corn \rightarrow crude oil: none
- Crude oil \rightarrow corn: previous crude oil volatility and previous crude oil market shocks affect the corn market. Effects are asymmetric.
- Crude oil \rightarrow ethanol: previous crude oil volatility and previous crude oil market shocks affect the ethanol market. Effects are asymmetric.

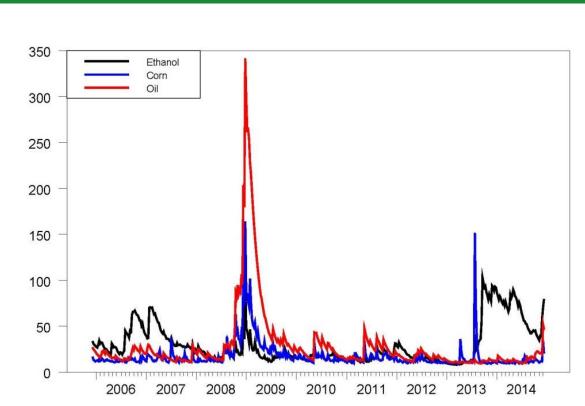

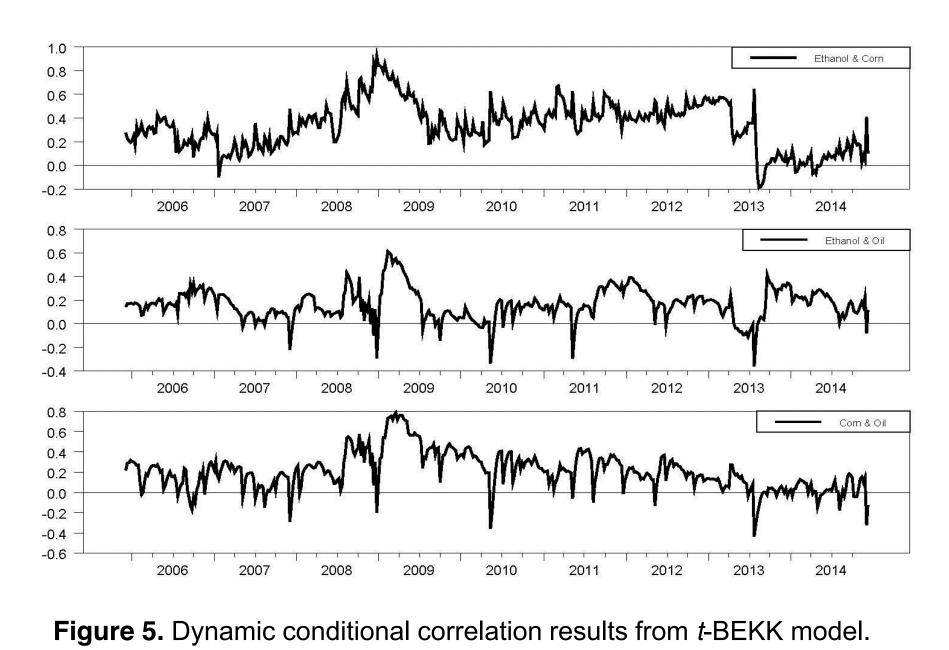

Figure 4. Conditional volatility results from *t*-BEKK model.

- the form:

Methods

• Our empirical approach consists of three steps:

Identifying a long run price relationship; Estimating a conditional means model that shows the relationship between price changes; and 3. Estimating a conditional variances model that shows the relationship between price volatilities.

Step 1 involves conducting Johansen trace tests for cointegration among the three unique pairs.

Steps 2 and 3 are estimated simultaneously using a t-BEKK model (Engle and Kroner, 1995), which has

 $\Delta \log(P_t) = c_0 + \sum_{j=1}^n \theta_j \Delta \log(P_{t-j}) + \gamma ECT_{t-1}I_{cointeg} + \varepsilon_t$

 $H_t = KK' + A'\varepsilon_{t-1}\varepsilon'_{t-1} + B'H_{t-1}B + C'\varepsilon^*_{t-1}\varepsilon^*_{t-1}C$

• Where $\varepsilon_t \sim (0, H_t)$, K is a lower triangular matrix; A, B and C are square matrices; and $\varepsilon_t^* = \min(\varepsilon_t, 0)$.

Conclusions

• We find similar results to existing studies regarding the nature of spillover effects between the corn and crude oil markets.

• Using a more recent dataset, the key result we find is the absence of a relationship between ethanol and corn and ethanol and crude oil. This is in contrast to the existing literature.

• We believe this result is due to the reaching of the blend wall mandate some time in late 2013.

• If the blend wall mandate continues to be met, this suggests that the close relationship between the ethanol and traditional food and fuel markets may be weakening.
