Investigation on culture and health status of Mrigal *Cirrhinus cirrhosus* from the farming system of Mymensingh region

G. U. Ahmed*, K. Konica, M. F. Ali¹ and T. Khatun

Department of Aquaculture, Bangladesh Agricultural University, Mymensingh-2202, Bangladesh and ¹Department of Aquaculture, Skeikh Fajilatunnesa Mujib Fisheries College, Melandah, Jamalpur, *E-mail: giasa50@gmail.com

Abstract

Indian major carp, *Cirrhinus cirrhosus* was considered to monitor culture and health status in farm condition from Bhaluka and Muktagacha of Mymensingh region of Bangladesh for a period of seven months starting from September, 2010 to March, 2011. Monthly sampling was carried out for growth and health condition. Samples of skin and muscle, gill, liver and kidney were observed by clinical and histological techniques. Water temperature was at unfavorable levels but, dissolved oxygen, pH, alkalinity, ammonia and nitrite of water were within the favorable range for fish culture during the months of December and January. Clinically weak body, rough skin, scale loss, thick gill filaments, ulcer and gray brownish color were observed. Among the affected fish organs like skin, muscle and gill were found to be more affected than those of the internal organs, liver and kidney. Major pathologies in the skin and muscle were loss of epidermis and dermis, presence of fungal granuloma, fungal hyphae, necrosis, hemorrhages, vacuums and melanocytes. Protozoan cysts, clubbing, hemorrhages, necrosis and hypertrophy were found in the gill. Necrosis, hemorrhage, pyknosis and vacuums were observed in liver. Common pathological signs like necrosis, hemorrhage, pyknosis, vacuums and degenerated kidney tubules were noticed in kidney. Overall, in the clinical and histopathological studies fishes were found to be more affected during the colder months i.e., December and January. Whereas, in the month of February the pathological condition of fish gradually started to heal up. In histopathological observation, fishes of Bhaluka farms were more affected than that of Muktagacha fish farms. Epizootic ulcerative syndrome (EUS) and protozoan diseases were noticed in Bhaluka fish farms.

Keywords: *Cirrhinus cirrhosus*, Clinical and Pathological condition

Introduction

The mrigal (*Cirrhinus cirrhosus*) is the most widely farmed species among the Indian major carps of the Indo-Gangetic floodplains of Bangladesh, India and Pakistan. It belongs to the family Cyprinidae of order Cypriniformes. It has advantages for possessing some special characteristics like higher disease resistance capacity, can tolerate wide range of environmental conditions and fast growing fish among the Indian major carps. It is also considered as an excellent food item, especially when the fishes are of moderate size. The mrigal fish culture enables to improve the socio-economic condition of the people of Bangladesh and can keep contribution to national economy.

For an increased production farmers of Mymensingh region are interested in semi-intensive fish culture. As the culture of Indian major carps has intensified there has also been an increased incidence of disease outbreak if due attention is not given. In Bangladesh fishes are suffered from various diseases such as epizootic ulcerative syndrome (EUS), fungal, parasitic and bacterial infections (Chowdhury *et al.*, 1999). In most cases hemorrhages, septicemia, lesions, gill damage are common symptoms of the diseased fish (Chowdhury, 1993 and 1998). Subasinghe (1995) suspected that water quality parameters such as total hardness, total alkalinity, dissolved oxygen, pH, fluctuation of temperature, ammonia, presence of fertilizers and pesticides could be associated with outbreak of diseases. Thus, maintenance of good water quality, nutrition, brood stock, species composition, stocking density etc. can control or at least reduce the outbreak of diseases in fishes. Indian major carps are highly susceptible to diseases in comparison to Chinese and European carps (Lilley *et al.*, 1992). Generally the epidemic occurs in the winter season (November to February) when temperature declines.

Clinical and histological procedures are important tools used to diagnose disease in fish. Ahmed and Haque (1999) found that clinical symptoms like grey white necrotic areas increase in December, January and February in various carp species of Bangladesh. Histology has been successfully used throughout the world. In Bangladesh, however, histological technique has limited application for disease diagnosis (Moniruzzaman, 2000). Ahmed *et al.* (1998) observed gill pathology having monogenetic trematode in juvenile of Indian major carps. Considering the above, the present study was undertaken to observe production and health status of mrigal from the farms of Mymensingh regions.

Materials and Methods

The experiment was carried out for a period of seven months from September, 2010 to March, 2011. Four farms were selected for the present study. Two ponds (Pond 1 and Pond 2) of two fish farms were located in Bohuli village of Bhaluka upazilla, Mymensingh district. It was about 40 km away from Mymensingh sadar. On the other hand, the rest of two ponds (Pond 3 and Pond 4) of two fish farms were located in Digholgoan village of Muktagacha Upazilla of Mymensingh district which was 16 km west from Mymensingh sadar. The area of pond 1 (P₁), pond 2 (P₂), pond 3 (P₃) and pond 4 (P₄) were 5.0, 2.5, 0.45 and 0.40 acres having water depth of 61.0 to 91.0 cm, 91.0 to 137.0 cm, 91.0 and 76.0 cm, respectively. The ponds were prepared by application of rotenone at a dose of 1 ppm for killing undesirable organisms and lime was applied at a dose 1kg/dec. Both the inorganic (Urea and TSP) and organic fertilizers (cow dung) were used. Doses were maintained as urea 100 g, TSP 90 g and cow dung 4 kg per dec. Chicken manures were soaked with sac in P₁. Ponds were stocked with 10 to 15 cm mrigal fry. Stocking density of P₁, P₂, P₃ and P₄ were 240, 220, 220 and 225 fry per dec, respectively. CP, Mega and ACI feed were applied in the ponds. Feed was given twice a day at the rate of 5% of the fish body weight in each pond. In P₃ water exchange facilities was available.

Water quality parameters like temperature, pH, dissolved oxygen, alkalinity, ammonia and nitrite were determined by using water quality parameter kits. Initial and final weight (g) of the fishes was measured at the beginning and at the end of the experiment. Clinical symptoms were observed immediately to record any injury, infection and abnormalities. Samples from various organs such as skin, muscle, gill, liver and kidney were collected and fixed in fixatives for histological analysis. The samples were then arranged in steel rack and dehydrated, cleared and infiltrated in an automatic tissue processor (SHANDON, Citadel 1000). The samples were then embedded with molten wax, steel mold and perforated plastic holder. Trimming was done from side and surface of the blocks with the help of scalpel and a microtome, respectively. The blocks were then sectioned at 5-7 micrometers by the microtome machine (Leica JUNG RM 2035). The sections were then stained with haematoxylin and eosin stains. After staining the sections were mounted with Canada balsam and covered by cover slips. Photomicrographs of the stained sections were done by using photomicroscope.

Results and Discussion

Water quality parameters are important considerations of production and health issues in fishes. It was observed that the highest water temperature (29.0°C) was recorded during March. Ahmed *et al.* (2009) observed that the value of temperature was 26.0°C during March in freshwater bodies of Mymensingh. In contrast the lowest temperature (18.0°C) was recorded in January. Ahmed *et al.* (2007) measured water temperature ranged from 19.5 to 29.5°C, while in December and January it was 19.5°C from two different farms of Mymensingh district. The dissolved oxygen content was ranged from 7.0 to 10.0 mg/l in four ponds. Ahmed *et al.* (2009) recorded dissolved oxygen ranged from 3.0 to 5.5 in four *beels* of Mymensingh. The dissolved oxygen content of water was fair in respect of fish culture. The pH values were ranged from 7.1 to 7.7 in four ponds. Ahmed *et al.* (2007) recorded that pH values ranged from 7.0 to 7.5 in different farms of Mymensingh district. So, from the above findings it can be mentioned that pH values obtained in the present research were within acceptable range for fish culture. Alkalinity of the experimental ponds were varied from 90 to 200 mg/l. Ahmed *et al.* (2009) found alkalinity varied from 38 to 68 mg/l in freshwater bodies of Mymensingh region. Reduced level of alkalinity was observed during December and January in the present study which had similarity with the findings of Ahmed and Banu (2001) who observed reduced alkalinity in freshwater bodies of Bangladesh during December and January. Ammonia value was ranged from 0.001 to 0.025 mg/l in all the ponds. However, it was observed that the values of ammonia were increased in December and January. Akter *et al.* (2009) observed increased level of ammonia during winter period.

It was seen that the highest growth rate and production were achieved in P₂ and P₃ where had lower fish density. This phenomenon indicated that there was a lower community feeding among the fishes which influenced them to take food properly and it might be absent in ponds with higher stocking density. Sardar *et al.* (1991) observed a decreased growth rate at the higher stocking densities when compared with the lower one and highest percentage of mortality was recorded in *Clarias gariepinus* fry.

Clinical observations revealed that fishes from all the ponds were apparently healthy and normal in appearance during the months of September, October and March (Fig. 1). Islam *et al.* (1999) observed that Indian major carps were found to have less affected during the month of March. However, in the month of November, mild signs like weak body, rough skin and scale loss were observed. According to Roy *et al.* (2006) rough skin, scale loss was found in November in various small species of open water bodies. It was found that the clinical signs were increased in December and January (Fig. 2). During this period weak body, rough skin, dermal lesions in ventral region, gray brownish color of the body and thick gill filaments were observed. Ahmed and Hoque (1999) monitored that symptoms like gray white necrotic areas increased in December and January in various carp species of Bangladesh. This result was also similar with the finding of Hoque (1998) and Islam *et al.* (1999) who reported that during the winter month infection was higher in various carp species of Bangladesh. However, *Cirrhinus cirrhosus* of Bhaluka especially in P₁ were clinically more affected compared to the fishes of other ponds and upazillas in the present investigation. Ahmed *et al.* (2007) found in *Anabas testudineus* that rough skin, scale loss and mild hemorrhage were observed in December, whereas, hemorrhage with reddish bright spots, fin loss and deep ulcer were evidenced at dorsoventral region of skin during January. According to Akter (2006) *M. aculeatus* and *M. cuchia* of Ailee beel in Bangladesh had rough skin, weak body, red spots and deep ulcer in December to January.

Histopathological examination of the present study showed that skin and muscle were almost normal in months of September, October and March in all the experimental ponds. Ahmed *et al.* (2007) observed that skin and muscle was normal in September and October in *A. testudineus* from two different farms of Mymensingh district. Less pathological changes such as loss of epidermis, necrotic muscles and vacuums were observed in November. According to Ahmed *et al.* (2009) epidermis and dermis were totally lost and some vacuums were seen in dermis and myotomes were arranged in normal fashion in skin and muscle of *M. cuchia* during November. Skin and muscle were severely affected like loss of dermis and epidermis and presence of fungal granuloma, fungal hyphae, necrosis, hemorrhage, vacuums and melanocytes in December and January (Figs. 3 and 4). Parveen *et al.* (2005) reported that epidermis was totally lost, many fungal granuloma were present in dermis and muscle, myotomes were ruptured and missing in many places during the months of December and January in Gangni Ox-bow Lake. Ahmed *et al.* (2009) cited that during winter season, increased pathologies were observed like epidermis and part of dermis was lost, highly necrotic and pyknotic muscles contained numerous fungal granulomas, especially towards the months of December and January. Pathological healing was started in February in all the ponds. From the presence of fungal granuloma and fungal hyphae in the muscle of P₁, it could be mentioned here that the fishes were affected with Epizootic Ulcerative Syndrome (EUS) in January. Hossain *et al.* (2009) also reported that during winter season, dermis and muscle were severely necrotic having huge vacuums, dermis partly lost, fungal hyphae and fungal granuloma in some small indigenous species.

The gills were found normal in September and October. Akter *et al.* (2009) observed that structure of gill of *A. testudineus* were almost normal in September and October. Less pathological changes such as hypertrophy, clubbing and few lamellar missing were recorded during November. Increased the pathological changes like presence of protozoan cyst, hypertrophy, lamellar missing, clubbing, hemorrhage, necrosis and primary gill lamellae separation were in the present experiment during December and January (Figs. 5 and 6). Similar findings were also recorded by Hoque (1995) with the gill lamellae of *C. cirrhosus* obtained from a private fish farm of Mymensingh area. Ahmed *et al.* (1998) found that hypertrophied gill lamellae with loss of secondary gill lamellae were evidence in *C. cirrhosus* of privately operated ponds. In March, gills were almost healed up to almost normal structure. Numerous protozoan cysts were recorded at the tip of the gill lamellae from P₁ and P₂ in winter season. From the presence of protozoan cysts in the gill, it was indicated that the fishes of P₁ and P₂ were affected with parasitic diseases in December and January. Ahmed *et al.* (2007) observed that protozoan cysts, marked hypertrophy, hyperplasia and necrosis in *A. testudineus* from two different farms of Mymensingh district during December and January.

Fig. 1. Healthy appearance of fish in March from P₁

Fig. 2. Ulcer and gray brownish color (↑) of fish in January from P₁

Fig. 3. Section of skin and muscle obtained from P₁ in January. Epidermis totally lost (↑), necrosis (n), fungal hyphae (fh), fungal granuloma (fg) and vacuums (v) were found in muscle. H & E × 235

Fig. 4. Section of skin and muscle obtained from P₄ in December. Epidermis totally lost, dermis partly lost (↑), sloughed off from muscle and muscle had wide vacuums (v), necrosis (n) and melanocytes (m). H & E × 125

Fig. 5. Section of gill recorded from P₁ in December. Gill lamellae had numerous protozoan cysts (pc), hypertrophy (hyp), clubbing (cb) and necrosis (n). H & E × 125

Fig. 6. Section of gill obtained from P₃ in January. Severely affected gill had lamellar missing (↑), hypertrophy (hyp) and hemorrhage (h). H & E × 125

Liver of fishes had mild necrosis, vacuums and hemorrhage in November. Ahmed *et al.* (2009) observed that liver had mild necrosis, hemorrhage and vacuums in *M. cuchia* from Ailee beel in November. Severe necrosis, pyknosis, vacuums and hemorrhages were observed during December and January (Figs. 7 and 8). Ahmed *et al.* (2004) found necrosis, hemorrhage and dense pyknotic cells in *N. nandus* from Kailla beel in the months of December and January. Hossain *et al.* (2009) recorded severe necrosis of hepatocytes, pyknosis, vacuums, fat droplets and hemorrhages during December and January. However, pathological healing was started in February in fishes of all the ponds and in March liver pathology was also recovered to give normal structure.

In case of kidney almost normal kidney structure were found in September, October and March. But in November, pathologies in kidney were found to be started with mild necrosis and empty spaces. Kidney was severely affected in December and January, with pathological signs such as degenerated kidney tubules, hemorrhage, necrosis, vacuums and pyknosis in many places (Figs. 9 and 10). Similar pathological symptoms of kidney of Indian major carps were observed by Hoque (1998) and Islam (1999). Ahmed *et al.* mentioned that the kidney had marked necrosis with wide vacuums and pyknotic cells in *N. nandus* and *C. punctatus* from Kailla beel in December and January. Pathologies were started to recover in fishes of all the ponds in February. Liver and kidney were less affected than external organs like skin and gill in this present study.

Fig. 7. Section of liver obtained from P₂ in January. Severe necrotic (n) hepatocytes, hemorrhage (h) and vacuums (v) were observed. H & E × 235

Fig. 8. Photomicrograph of liver obtained from P₃ in January. Marked necrosis (n), hemorrhage (h), pyknosis (p) and vacuums (v) were observed. H & E × 235

Fig. 9. Photomicrograph of kidney obtained from P₁ in January. Kidney tubules were degenerated (dt) and resulted in wide vacuums (v) and marked necrosis (n). H & E × 125

Fig. 10. Section of kidney obtained from P₃ in January. Degenerated kidney tubules (dt), necrosis (n), hemorrhage (h) and vacuums (v) were observed. H & E × 125

Clinically and histopathologically, it was observed that, sampled fishes were found normal during the months of September and October. Conversely, in November mild pathological changes in organs were observed. However, fishes were more affected when temperature was reduced in winter season. Ahmed *et al.* (2009) found that fishes of all the Ox-bow lakes were affected in the colder months of the year i.e. in December and January when water temperature drops to minimum levels (16°C). Ahmed and Hoque (1999) mentioned that in freshwater fish, EUS outbreak was severe during cooler months of the year when temperature and alkalinity were reduced at their minimum levels. So, it could be assumed that low temperature, along with alkalinity might have played an important role in outbreak of diseases like EUS and protozoan disease. On the other hand, reduced pathological changes were recorded in February and March. Organ wise, gill had an increased pathology in all the ponds and months when compared to other organs.

Conclusion

In the present investigation most of the examined fishes of four ponds were more or less normal and healthy from external observations. But histopathologically, a large percentage of the fishes were affected by numerous protozoan cysts and fungal granuloma during the cold period in P₁ of Bhaluka. This might be due to application of raw chicken manure to the pond and low temperature. Among the farms, clinically and pathologically cultured fishes of farms in Bhaluka were found to be more affected than fishes of the farms of Muktagacha. This is due to poor management practice such as high stocking density, over use of organic fertilizer and lack of regular monitoring. So, steps should be taken to overcome the problems. Attention should be given towards cooler months of the year when fishes suffered from various diseases. Stocking density should be reduced by regular harvesting during the period, liming and salting prior to winter season, balance diets, water quality should be in controlled condition which will ultimately reduce stress, infection and diseases in fishes.
