Preface

Research for this report was conducted under North Dakota Agricultural Experiment Station Research Project No. 1376. This report, which contains an extensive look at the profitability of retaining ownership, is an extension of "Comparing the Profitability of Beef Production Enterprises in North Dakota," Agricultural Economics Report 210.

The authors would like to thank Brenda Ekstrom and Roger Johnson of the Department of Agricultural Economics; Harlan Hughes, livestock economist, Cooperative Extension Service, NDSU; LaDon Johnson and Russell Danielson of the Department of Animal and Range Sciences; and Olin Cox of Juhl's Nutrition and Management Services for their helpful suggestions, ideas, and comments throughout the development and review of this study. The authors would also like to thank the following for their cooperation and the information they provided:

Brookover Cattle Company, Inc.
Hendrickson Land and Cattle Company
Hertz-de Baca Cattle Management Company
Juhl's Nutrition and Management Services, Inc.
Onida Feeders, Inc.

Special thanks are due to Jody Peper for her diligence in typing the manuscript and to Carol VavRosky for the quality figures she provided.

Highlights

Cow-calf producers, because of their position in the beef production process, are especially vulnerable to the price extremes that characterize the cattle cycle. They receive a culmination of losses that occur as lower slaughter and feeder cattle prices and feeding losses are passed through the system. In light of this, cow-calf producers need to evaluate marketing alternatives to selling weaned calves.

The objective of this study is to estimate the profitability of several options of retained ownership, including custom feeding. Cost of production budgets were constructed at 1984 price levels for a typical cow-calf operation in North Dakota and for the retained ownership alternatives considered. The cost components of these budgets were adjusted back over time using indices of prices paid by farmers. Total production costs were divided by expected output to estimate break-even prices. Estimated profitability per cow was derived by subtracting the break-even price from the market price and multiplying by expected output.

Producers can usually increase profit per cow by retaining ownership of calves. There were several years, however, when selling weaned calves was the most profitable alternative. While retaining ownership reduced price risk relative to the cow-calf operation, the alternatives considered were still exposed to significant price risk. Availability of sufficient additional capital and the increased managerial requirements are important factors to consider when deciding to custom feed.

RETAINED OWNERSHIP - PRODUCTION AND MARKETING
ALTERNATIVES FOR COW-CALF PRODUCERS

Randall D. Little, David L. Watt, and Timothy A. Petry*

The cattle cycle, with its fluctuations in inventory and prices, imposes a unique set of risks on beef production. Cow-calf producers, because of their position in the beef production process, are especially vulnerable to the price extremes that characterize the cattle cycle. Slaughter plant and feedlot operations are capable, to some extent, of passing some of their losses along in the system. Their decisions to buy and at what price are based on anticipated market conditions at the expected time of sale. For example, if a feedlot operator expects a difficult period in the future, his bid price for feeder cattle will be adjusted accordingly. He also has the option to operate at less than full capacity or to discontinue feeding. The cumulative effect of feedlot managers' decisions heavily influences demand for weaned calves. Cow-calf operators often have little choice but to accept lower prices. Thus, cow-calf operators receive a culmination of losses that occur as lower slaughter and feeder cattle prices and feeding losses are passed through the system (Hasbargen et al. 1983).

Cow-calf operators need to evaluate marketing alternatives to selling weaned calves. The objective of this study is to estimate the potential benefits of vertical integration by cow-calf producers. A historical approach is used involving annual calf crops from 1958 to 1983. Vertical integration, defined as the combination and coordination of successive production and/or marketing stages within one firm (Cramer and Jenson 1979), provides alternatives to the traditional marketing plan of selling weaned calves in the fall. The vertical integration alternatives examined in this study involve retaining ownership of calves beyond weaning for sale as light or heavy yearlings or slaughter cattle. Retaining ownership enables producers to delay marketing during periods of depressed feeder cattle prices. Tax implications of retaining ownership are not considered in this study.

Retaining ownership should reduce the total cost of gain for the cow-calf producer. Studies have shown that cow-calf operations selling weaned calves are less profitable than operations that retain ownership (Ford et al. 1985; Lambert and Sands 1984; and Whitley and O'Connor 1981). Lambert and Sands (1984) concluded that retained ownership through slaughter was profitable in six of the nine years studied, while selling the same calves at weaning would have been profitable in only three years. They also concluded that because seasonal price tendencies for calves and fed cattle generally favor retained ownership, the cattle feeder can improve his odds of both avoiding seasonally low calf prices and achieving seasonally high fed cattle prices. Ford et al. (1985) concluded that live weight marketed and profitability were increased when ownership of the animal was maintained and that retained ownership through the feedlot finishing phase produced the highest profitability of the strategies studied.

*Little is a research assistant, Watt is assistant professor, and Petry is associate professor, Department of Agricultural Economics, North Dakota State University, Fargo.

Custom feeding is defined in this study as maintaining ownership of cattle and the right to major management decisions concerning those cattle which have been physically relocated to another's lot for growing and/or finishing where daily supervision is the responsibility of a second party. Producers who custom feed are paying for the feeding services and expertise of the feedlot operator.

The profitability of the following production alternatives will be estimated and evaluated:

1. Cow-calf;
2. Cow-calf and backgrounding;
3. Cow-calf and wintering;
4. Cow-calf, wintering, and pasturing;
5. Cow-calf and custom backgrounding;
6. Cow-calf and custom feeding a weaned calf;
7. Cow-calf, backgrounding, and custom feeding;
8. Cow-calf, wintering, and custom feeding; and
9. Cow-calf, wintering, pasturing, and custom feeding.

Description of the Situation

Beef production is a vital part of the agricultural industry in North Dakota. The sale of cattle and calves is a major source of cash farm receipts, ranking second to wheat in 1983. Receipts for the sale of cattle and calves accounted for 17 percent of total cash receipts for all crop and livestock products and 69 percent of total cash receipts for all livestock products in 1983 (North Dakota Agricultural Statistics 1985).

The cow-calf enterprise is the major beef enterprise in North Dakota. Beef cows constituted about 91 percent of the total cow herd in North Dakota at the beginning of 1985 (North Dakota Agricultural Statistics 1985). According to the Census of Agriculture, the average-sized beef cow herd in North Dakota had 77 cows. About 44 percent of the farms and ranches with beef cows had between 50 and 200 head.

Virtually all calves produced in the state are either sold at weaning; backgrounded and sold in the spring; or wintered, pastured, and sold the next fall. The number of calves sold at weaning or held for further feeding is contingent primarily upon feed availability. A greater proportion of the calf crop is fed beyond weaning in years of ample moisture when feed supplies are adequate. But in years when feed is inadequate, more calves are sold in the fall at weaning. Feeder calves sold in North Dakota are generally shipped out of state for finishing. Very few calves are fed to slaughter weight in North Dakota.

Risk

Risk and uncertainty are interchangeable terms used to describe an action selected by a decisionmaker that has alternative outcomes (Boehlje and Eidman 1984). The risks farmers face can be divided into two broad types, business and financial.

Business risk is defined as the inherent uncertainty in the firm independent of the way it is financed. The major sources of business risk are price and production risk. Price or market risk, which is the source of risk considered in this study, is the result of factors that lead to unpredictable shifts in supply and demand of inputs and products. Seasonal, cyclical, and trend natures of prices are predictable to some extent, but the inability to accurately predict prices and price movements is the source of price uncertainty. Many government actions concerning trade agreements, embargoes, and fiscal and monetary policy contribute to price variation. Production risk, the second source of business risk, is the result of factors affecting the production level that are beyond the manager's control, such as weather, disease, insect damage, and changes in governmental regulations. Production is reflected in variability in yields per acre, weaning weights, rate of gain, and other variables used to measure the amount of physical production (Boehlje and Eidman 1984).

Financial risk is defined as the added variability of net returns to owner's equity that results from the financial obligation associated with debt financing (Boehlje and Eidman 1984). Financial risk also includes uncertain loan availability and fluctuating interest rates, which reflect the price of debt capital. It deals primarily with the firm's ability to meet long-run claims and increases as leverage increases (Barry, Hopkins, and Baker 1979). Leverage, which is measured by the ratio of debt to equity, multiplies the potential financial return or loss that will be generated with different production and price levels.

Costs of Production

Budgets reflecting the costs of production of several beef cattle enterprises typical to North Dakota and the custom feeding options were constructed at 1984 price levels (Appendix A). The budgets included a cow-calf operation; backgrounding, wintering, and pasturing steers and heifers; custom backgrounding steers and heifers; and custom feeding weaned, backgrounded, wintered, and wintered and pastured steers and heifers.

The approach used to construct these budgets is based on the "opportunity cost" (returns foregone in the best alternative use) of resources employed. When using the opportunity cost method, inputs are valued using current market prices, rather than what may have actually been paid for the inputs. Examples of resources that are valued differently using the opportunity cost method include feed, which may be cheaper when produced on the farm than if purchased; operator and family labor, which generally remains unpaid; pasture rent, which is unpaid for owned land; and interest expenses, which would not be paid when inputs were paid for at the time of purchase (Johnson et al. 1986).

There is much variation in production costs among producers. Differences occur due to production practices, managerial ability, and size and type of machinery employed. This variability means that the costs individual producers incur (and consequently their profitability) may vary considerably from the estimate of average costs presented. Conclusions reached, therefore, do not apply to producers with costs significantly

different from the average. However, the trends indicated should provide a general idea of the profitability of the cattle enterprises considered over time.

The Cow-Calf Operation

The cow-calf production costs were based on an average-sized spring calving operation.¹ The operation weaned calves from 90 percent of the cows and heifers assumed bred. It was assumed that cow-calf operators replaced 16 percent of brood cows annually. To allow for this they retained 18 percent of their calves, all heifers, from which replacements were chosen. Cull cows and cull replacement heifers weighed 1,000 and 750 lbs., respectively. Weaned steers and heifers weighed 425 and 400 lbs., respectively. There were 45 percent of a steer (half of the 90 percent calf crop) and 27 percent of a heifer (half of the 90 percent calf crop minus the 18 percent retention rate) sold per cow each year.

Backgrounding and Wintering

Backgrounding and wintering are winter feeding programs common in North Dakota. Backgrounding emphasizes a higher rate of gain that requires feeding a high protein and energy ration. Calves enter the backgrounding program after weaning in the fall and are sold or custom fed in the spring. Program length was assumed to be 150 days. Steers entered the backgrounding program at 425 lbs. and were fed to a market weight of 675 lbs. Heifers entered the program at 400 lbs. and were marketed at 625 lbs. The average daily gains for steers and heifers were 1.7 and 1.5 lbs., respectively.

The wintering program involves low weight gains and an inexpensive, high roughage diet. Calves enter the wintering program in the fall and are typically either sold or pastured in the spring. Program length was assumed to be 150 days. Steers weighed 425 lbs. and heifers weighed 400 lbs. when entering the program and 675 lbs. and 535 lbs., respectively, at the end. Average daily gains for wintered steers and heifers were 1.0 and 0.9 lbs., respectively.

Wintering and Pasturing

Many producers follow a wintering program with a pasturing program when sufficient forage is available. Compensatory gain is higher for wintered calves than for backgrounded calves, so their capacity for growth on pasture is greater. The pasturing program was assumed to be 120 days. Steers and heifers entered the pasturing program weighing 575 and 535 lbs., respectively.

¹The methodology used in this report to estimate production costs per cow is basically the same as that used in an earlier report, Comparing Profitability of Beef Production Enterprises in North Dakota. However, one change has been implemented. The change in the value of the cow, which was previously included, is no longer taken into account.

Steers weighed 800 lbs. and heifers 740 lbs. at the end of the program. Average daily gains for pastured steers and heifers were 1.9 and 1.7 lbs., respectively.

Custom Feeding

Several custom feeding options are considered in this paper. The following basic assumptions apply to each alternative. Truckloads of animals weighing 50,000 lbs. each were shipped 450 miles to a feedlot. A one-way transportation charge of \$1.81 per mile was used. A 4 percent transit shrink was assumed for all animals shipped to the feedlot. All animals were sold at the feedlot with a 3 percent pencil shrinkage subtracted in lieu of additional marketing charges.

Steers and heifers in the custom backgrounding program weighed 408 and 384 lbs., respectively, upon arrival at the feedlot and 700 and 650 lbs. at the time of sale. Average daily gains were 1.85 lbs. for steers and 1.67 lbs. for heifers. The feeding period was 158 days for steers and 150 days for heifers.

Weaned calves going directly to custom feedlots in the fall weighed the same as those entering the custom backgrounding lots. However, these calves were fed to slaughter weight. Steers weighed 1,100 lbs. and heifers 970 lbs. when sold. Steers were fed to gain 2.0 lbs. per day up to 700 lbs. and 3.0 lbs. per day from 700 to 1,100 lbs. Heifers were fed to gain 1.8 lbs. per day to 650 lbs. and 2.7 lbs. per day from 650 to 970 lbs. Custom feeding weaned steers and heifers to slaughter weight took 280 and 267 days, respectively.

Backgrounded steers and heifers weighed 648 and 600 lbs., respectively, when entering the custom feedlot. Average daily gains for steers and heifers were 3.0 and 2.7 lbs. It was assumed to take 151 days for a backgrounded steer and 138 days for a backgrounded heifer to reach slaughter weight.

Wintered steers and heifers weigh 552 lbs. and 514 lbs., respectively, when entering the custom feedlot. Average daily gains were 3.0 and 2.7 lbs. It took 183 days for a wintered steer and 170 days for a wintered heifer to reach slaughter weight.

Wintered and pastured steers and heifers weighed 768 and 710 lbs., respectively, when entering the feedlot for custom feeding. Average daily gains for steers and heifers was 3.0 and 2.7 lbs. It took 111 days to feed a wintered and pastured steer and 97 days to feed a wintered and pastured heifer to slaughter weight.

Livestock Prices

The market prices used in this study were compiled from 1958 to 1984 (Appendix B). The prices from 1963 to 1984 for steers and heifers marketed in North Dakota were based on USDA Market News Service prices received at West Fargo for No. 1 muscle thickness, medium-frame feeder cattle. USDA prices were unavailable prior to 1963, so prices received at Kansas City were adjusted using simple linear regression and used as proxies from 1958 to 1962.

Regressions were computed between 10 years of prices from the two sources, with West Fargo prices as the dependent variable and Kansas City prices as the independent variable. The regressions examined the relationship between the prices at the two locations for 400-500 lb. steers and heifers, 500-600 lb. steers and heifers, 600-700 lb. steers and heifers, and 700-800 lb. steers and heifers. The equations generated in the regressions as well as the coefficients of determination (R^2) values and T-values are included in Appendix B. It should be noted that the regression results yielded fairly high R^2 and T-values, which demonstrate a strong relationship between the cattle prices from the two sources.

Prices used in the custom backgrounding and feeding options were based on 600-700 lb. choice steer and heifer yearlings at Kansas City and 900-1,100 lb. choice slaughter steers and heifers at Omaha. Cull cow prices were based on the annual average prices received by farmers for beef cows in North Dakota.

Market prices used were three month averages of prices received around the expected sale date. Weaned calf prices were based on September, October, and November prices. Backgrounded, wintered, and custom backgrounded calf prices were based on March, April, and May prices. Pastured calf and custom-fed, weaned calf prices were averages of August, September, and October prices. Prices for custom-fed, backgrounded calves were averages of September, October, and November prices; custom-fed, wintered calves, October, November, and December prices; and custom-fed, wintered, and pastured calves, the averages of December, January, and February prices.

Methodology

The production cost components were adjusted for price changes over time back to 1958 using indices of prices paid by farmers (Appendix C). Per cow production costs are divided by the hundredweights (cwt) of expected output to derive an estimate of a breakeven price that would cover all costs using this equation:

$$BE = (CC_t + WP_t + PP_{t+1} + CF_{t+1})/EO$$

where

BE = Breakeven price per cwt produce

CC_t = Cow-Calf production costs in year t

WP_t = Winter feeding program production costs in year t
 $WP_t = (.45 \times \text{steer winter program costs} + .27 \times \text{heifer winter program costs})$

PP_{t+1} = Pasturing program production costs in year t+1
 $PP_{t+1} = (.45 \times \text{steer pasturing costs} + .27 \times \text{heifer pasturing costs})$

CF_{t+1} = Custom feeding program production costs in year t+1,
 $CF_{t+1} = (.45 \times \text{steer custom feeding costs} + .27 \times \text{heifer custom feeding costs})$

$$\begin{aligned} \text{EO} &= \text{Expected output per cow} \\ \text{EO} &= (.45 \times \text{expected steer selling weight} + .27 \\ &\quad \times \text{expected heifer selling weight}) \end{aligned}$$

The percentages used to adjust the steer and heifer production costs and expected selling weights reflect the percentage of steers and heifers sold per cow in the herd. It was assumed that 45 percent of a steer (half of the 90 percent calf crop) and 27 percent of a heifer (half of the 90 percent calf crop minus the 18 percent retention rate) were sold per cow. Production costs of feeding programs were included only when applicable, otherwise they equal zero in the equation. For example, if a calf was sold at weaning, then all production cost terms would equal zero except the cow-calf production costs, while if the calf was wintered, pastured, custom fed, and then sold, each production cost term would be included to reflect the costs of each production segment.

The break-even price was subtracted from an adjusted market price to derive an estimate of profit per cwt. The adjusted market price was equal to 63 percent $(.45/ (.45 + .27))$ of the steer price plus 37 percent $(.27/ (.45 + .27))$ of the heifer price, which reflects the combination of steers and heifers that are sold per cow. Profit per cwt was multiplied by the cwt of expected output per cow to yield an estimate of the profit per cow.

Results

Perhaps the best method of evaluating retained ownership is comparing production costs and profitability involved with calves from a given calf crop. The increased capital requirements of retained ownership are evident (Table 1). For example, it cost \$246.53 to produce a weaned calf for sale in the fall of 1983. However, it cost an additional \$268.36 to winter, pasture, and custom feed that calf for sale at the end of 1984. The availability of funds to finance extended feeding programs should be of primary importance when considering retaining ownership.

The profitability in dollars per cow of the cow-calf operation and the retained ownership alternatives is presented in Table 2. The cow-calf operation was profitable in 16 of the 26 years studied. Returns averaged -\$1.32 per cow over the study period (Table 3). The most profitable retained ownership alternative was custom feeding weaned calves, which was profitable in 20 years and averaged \$30.85 per cow. Factors contributing to the higher profitability of this option include lower interest costs due to the shorter length of the feeding period, the high energy ration and rapid rate of gain, less transportation shrink, and sale before the seasonally low fall prices.

The cow-calf wintering, pasturing, and custom feeding program was next with an average profit per cow of \$16.33. This option was profitable in 17 years. The cow-calf, backgrounding, and custom feeding option was profitable in 17 years, and it averaged \$15.84 per cow. The cow-calf, wintering, and pasturing and the cow-calf and backgrounding options averaged \$14.31 and \$11.63 per cow, respectively. Both were profitable in 17 of the years studied.

Variability in profit, which is measured by the standard deviation, is very high for each production alternative considered. Retaining ownership increased variability over the cow-calf operation, with the exception of the cow-calf and custom feeding option. However, the increases in the standard deviation were not significant.

The coefficient of variation (CV), which is the standard deviation divided by the mean, provides a measure of variation relative to earnings. The CV provides a means of comparing the riskiness and, in this case, price risk of production alternatives. The large negative CV of the cow-calf operation is the result of its negative profit margins and high variability. Retaining ownership reduced risk considerably, relative to the cow-calf operation. However, all production alternatives were still exposed to significant price risk. The probability of generating negative profits in any given year is high. The cow-calf and custom feeding weaned calves and cow-calf and custom backgrounding options had the lowest CV values, indicating they had the lowest associated price risk of the options considered. The CV values for the remaining retained ownership alternatives, with the exception of the cow-calf and wintering option, were quite similar.

The potential benefits of retained ownership are illustrated in Figures 1 through 5. Profit per cow in the cow-calf operation in one year should be compared with profit per cow in the cow-calf and retained ownership alternative in the following year to determine any impact on profitability of retaining ownership of a given calf crop. Cow-calf producers could have improved profitability per cow by retaining ownership rather than selling at weaning in most of the years studied. Sale of calves at weaning was the most profitable of all production alternatives in 1973 and 1980.

The Decision to Custom Feed

Custom feeding enables cow-calf producers with sound, progressive breeding programs to capitalize on more breeding improvements than just increased weaning weights. It also provides a way in which producers can capture any profits backgrounders and cattle feeders would have realized. However, feeding to slaughter weight will delay earnings four to ten months. Capital requirements will increase substantially because of the longer period of ownership. A producer that custom feeds is bound by contract with the feedlot, establishing a security interest in the cattle until all charges have been paid.

Selecting a Custom Feedlot

Custom feedlots sell feeding management and expertise, which is the basis upon which they compete. Producers should investigate carefully before selecting a feedlot because of the variety of services offered and methods of handling financial details (Doane's Agricultural Report 1982).

Location of the feedlot with respect to weather, shipping distance and transportation costs, and proximity to feed supplies and packing houses is important. Low-humidity climates are preferred because performance typically drops when humidity is high. When low-cost, locally grown feed is available, it can provide a feedlot with an attractive competitive edge. The proximity

Figure 1. Estimated Profitability Per Cow on the Cow-Calf and Cow-Calf and Backgrounding Operations in North Dakota, 1958 to 1984

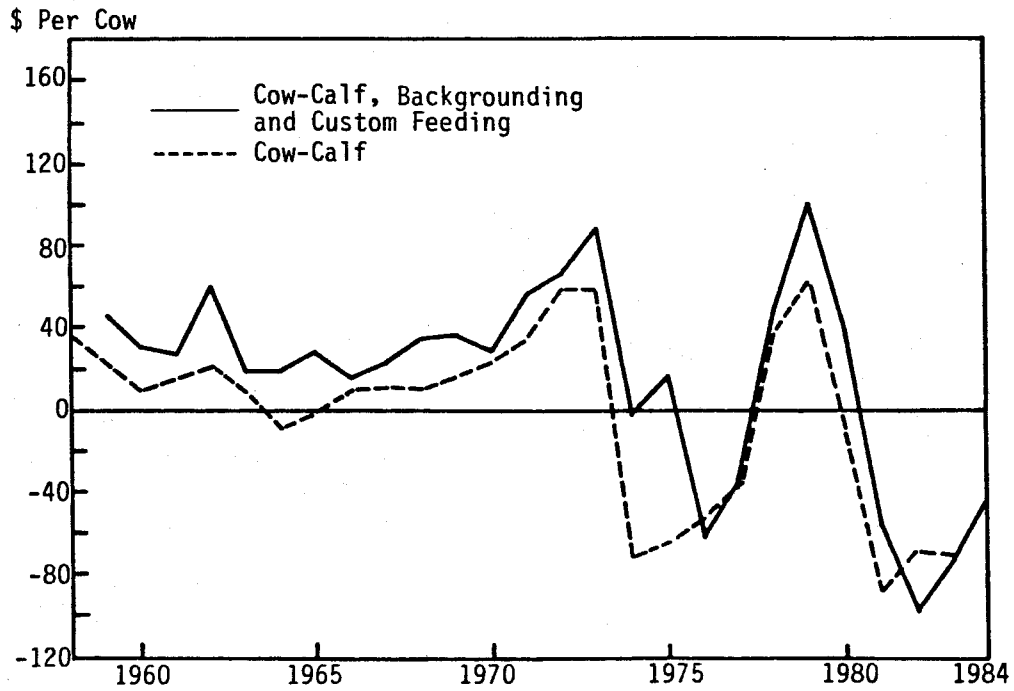

Figure 4. Estimated Profitability Per Cow on the Cow-Calf and Cow Calf, Backgrounding and Custom Feeding Operations in North Dakota, 1958 to 1984

Figure 5. Estimated Profitability Per Cow on the Cow-Calf and Cow-Calf, Wintering, Pasturing, and Custom Feeding Operations in North Dakota, 1958 to 1984

of several packing plants is important because this increases the potential number of competitive price bids for finished cattle.

A good place to start in the search for a custom feedlot is by talking with other producers who have custom fed cattle. They can provide important information about feedlots with whom they have dealt or recommendations of others to try. Extension specialists in the area where the cattle are to be fed are another good source of information.

After selecting several feedlots for further consideration, it is important for the producer to take the time to visit each. It is during these visits that he will meet the people he will be dealing with. During these visits the producer should learn as much as possible about the feedlot's operation and management. He should evaluate the general appearance of the feedlot; a clean, well-maintained operation should be a reflection of its management. Other items to note include availability of clean water in properly located water tanks, adequate shelter, usable handling and loading facilities, location of the mounds, width of the concrete apron along feed bunks, and the space per head in the lot and at the feed bunk. Mounds should be six to eight feet high and six feet wide at the top (Minish and Fox 1982) and should be built near the concrete feeder apron to keep the cattle nearer the feed bunk. Cattle require 150 square feet per head in the lot and 25 square feet per head on the mound in a sloping well-drained dirt lot with

mounds, and 400 square feet per head in the lot and 25 square feet per head on the mound in a nearly level dirt lot with mounds. Feeder cattle over 600 lbs. require about 22 to 26 inches of feeder per head (Minish and Fox 1982).

Rather than contracting directly with a custom feeder, a cow-calf producer may consider contracting with a livestock management company. Livestock management companies serve as agents managing cattle for owners who want their cattle custom fed. They take care of the details involved with custom feeding that a cow-calf producer with little experience in custom feeding may miss. They evaluate and select the feedlots and typically have someone who visits the feedlots periodically, preferably unscheduled, to check progress and performance. This is an important service to an owner living far from the feedlot.

Livestock management companies also help develop marketing plans that meet the owner's goals. Because this often involves hedging, the cattle management company should be equipped and prepared to provide that service. Many are also capable of providing financing to qualified cattle owners who want to custom feed but choose not to finance with their local banks.

Systems of Payment

Two types of costs, direct feedlot service charges and ownership costs, are incurred when custom feeding. The direct feedlot charges include feed costs; yardage charges which feedlots use to cover operating and fixed costs; veterinary treatment charges to cover a routine vaccination, dipping, and a worming program for incoming cattle; and hazard insurance to cover losses from windstorms, lightning, etc. and death loss over 10 percent. The ownership costs include interest on the cattle investment, interest on feedlot charges, and transportation expenses.

Guyer (1975) lists the following methods of calculating payment from owner to feeder currently being used:

1. Feed costs plus yardage
2. Feed mark-up (to cover yardage)
3. Price per pound of gain
4. Price per head per day

Feed cost plus yardage is the approach used most often when feeders have the capability to weigh feed. When using this type of contract, the cattle owner should be concerned about record accuracy, the quality of health management, competitive feed prices, lot design and management, and specified goals the cattle are fed to meet.

The feed mark-up method is used by some feedlots to cover milling costs and yardage charges. A dry matter or 90 percent dry matter basis is preferred for the mark-up in order to compare yardage costs more accurately. The same concerns to the cattle owner apply to the feed mark-up method as the feed cost plus yardage.

The price per pound of gain method is typically used by feedlots that do not have facilities available to weigh feed. This type of arrangement

provides motivation for the feeder to use the best management practices to obtain high rates of gain at least cost, which, in turn, should be advantageous to the owner because health problems and death loss may be minimized.

Contracts based on a flat price per head may be best when the owner is willing to accept rather low rates of gain. This type of contract is useful when calves utilize unharvested crop residues, winter range, or other feeds when daily feed intake and cost of gain are difficult to measure. However, certain stipulations should be added to the contract such as bonuses for a low death loss or for meeting a minimum average daily gain and to provide incentives for the feeder to provide good management.

The Contract Arrangement

Satisfied parties to a contract arrangement can exist only if both parties are fully informed and all important points are covered by the contract. Guyer (1975) lists the following factors that should be included in detail in custom feeding contracts.

Weighing conditions, including fill procedures to be used prior to weighing, when and where calves are to be weighed, and allowable pencil shrink should be agreed upon when the contract price is set. Care should be taken so feeders will not be penalized when cattle enter the feedlot with too much fill nor should the owner pay for excessive fill at the time of sale.

Assigning responsibility for death loss is very important. Excessive death loss as a result of poor cattle health should not be charged to the feeder. Neither should the owner be expected to absorb excessive death loss resulting from negligent health management practices by the feeder. Many contracts specify that the owner stand all death losses for a specified period of time after arrival at the feedlot, typically one month. After that the feeder and owner may share the death loss.

Veterinary, medicine, and immunization costs should be paid by the owner. Feeders should insist that vaccinations, dehorning, castration, etc. be done prior to arrival at the feedlot. If the feeder must perform these operations after arrival, cost of gain should be adjusted to give the feeder adequate compensation for the lost gain due to the stress of treatment and other costs involved.

A minimum and maximum length of the feeding period should be specified. Cost of gain is usually high for short growing periods because time is needed for adjustment and recovery from shipment. Cost of gain is also higher in long growing periods as cattle reach heavier weights. Weight of cattle should also be specified because lightweight cattle gain at less cost than heavier feeders.

Both owners and feeders may benefit from including guidelines regarding rate of gain in the agreement. Faster rates of gain are usually lower cost gains when a given final weight is the terminal point in the feeding program. However, faster gaining cattle that are fed for a given period of time finish

at a heavier average weight. Fast gains during the growing phase are offset to some extent by the slower and more expensive rate of gain in the finishing phase.

The method and timing of payments or financing arrangements are very important. Partial payments made during the feeding period, usually at bi-weekly or monthly intervals, reduce the interest payments for feed and yardage charges the owner would have to pay. If financed, cash outlay during the feeding period is usually not required.

The terms of the contract should give the feeder a security interest in the cattle until all charges have been paid. Feeders should familiarize themselves with laws governing liens and mortgages to ensure payment for feed and services rendered. Owners should also be aware of their rights if they are mortgaging their cattle. The feeder must notify the holder of the mortgage of his intent to assert his lien for feeds and services within 10 days of receipt of the cattle if he wants his lien to be considered first.

An example of a contract arrangement between a custom feeder and a cattle owner is presented in Appendix D. This sample contract simply provides an outline to follow. It should not be used until appropriate amendments tailoring it to individual situations are added and it has been checked for compliance with the laws of the appropriate state.

Summary and Conclusions

The objective of this study was to discuss the potential benefits of retaining ownership in cow-calf operations. Eight alternatives of retained ownership were examined, 1) cow-calf and backgrounding; 2) cow-calf and wintering; 3) cow-calf, wintering, and pasturing; 4) cow-calf and custom backgrounding; 5) cow-calf and custom feeding a weaned calf; 6) cow-calf, backgrounding, and custom feeding; 7) cow-calf, wintering, and custom feeding; and 8) cow-calf, wintering, pasturing, and custom feeding. Profitability per cwt produced and per cow and average return on production cost were estimated from 1958 to 1984. The budgets used to estimate costs of production were based on the opportunity cost of the resources used.

Results indicated that beef production, especially the cow-calf operation, is exposed to significant price risk. The use of three-month average market prices to calculate profitability probably reduced the price risk that individual producers actually face when selling cattle on one particular day. This riskiness reflects the need for informed managerial involvement in production and marketing decisions. As the risks in beef production increase, the level of management should increase as well, especially with respect to financing. Exposure to financial risk should be minimized.

Retained ownership was shown to be a viable production and marketing alternative that can reduce the price risk inherent to the cow-calf operation that markets weaned calves. However, all production alternatives considered in this paper were exposed to considerable price risk. Retaining ownership increases the cost of ownership in terms of the additional operating capital required. An operation's cash flow must be carefully analyzed prior to

considering retaining ownership due to the increased operating expense burden, especially in the first year.

Producers must also consider the additional production risk of custom feeding because the animals are outside their personal management control. According to the results of this study, cow-calf producers could improve profit per cow considerably by retaining ownership. There were several years, however, when selling calves at weaning was the best alternative for maximizing profit.

It should be noted that the estimates of profitability discussed in this study are returns to management. Because retaining ownership requires a higher level of management, the increased returns may not offset the costs inherent to the additional management.

Appendix A

COW-CALF BUDGET (1984)

	(Per Cow)
Feed Expense	\$106.66
Pasture Rent 7 AUM @ \$8/AUM	56.00
Labor 8 hrs @ \$4.20/hr	33.60

APPENDIX TABLE B2. EQUATIONS USED TO ADJUST KANSAS CITY PRICES TO WEST FARGO PRICES

Regression Equations

400-500# Steers

$$\text{West Fargo Price} = -1.8201946 + (1.0343523 \times \text{Kansas City Price})$$
$$R^2 = .978$$
$$T\text{-Value} = 35.155$$

400-500# Heifers

$$\text{West Fargo Price} = -3.2100313 + (1.1254112 \times \text{Kansas City Price})$$
$$R^2 = .972$$
$$T\text{-Value} = 31.107$$

500-600# Steers

$$\text{West Fargo Price} = -1.7479408 + (1.0194804 \times \text{Kansas City Price})$$
$$R^2 = .988$$
$$T\text{-Value} = 48.229$$

500-600# Heifers

$$\text{West Fargo Price} = -1.0131856 + (1.03754 \times \text{Kansas City Price})$$
$$R^2 = .990$$
$$T\text{-Value} = 61.98$$

600-700# Steers

$$\text{West Fargo Price} = -2.1280667 + (1.0340014 \times \text{Kansas City Price})$$
$$R^2 = .984$$
$$T\text{-Value} = 41.624$$

600-700# Heifers

$$\text{West Fargo Price} = 1.9244081 + (.9436183 \times \text{Kansas City Price})$$
$$R^2 = .773$$
$$T\text{-Value} = 11.68$$

700-800# Steers

$$\text{West Fargo Price} = -.5434368 + (.9881594 \times \text{Kansas City Price})$$
$$R^2 = .987$$
$$T\text{-Value} = 45.332$$

700-800# Heifers

$$\text{West Fargo Price} = 4.1015440 + (.8410749 \times \text{Kansas City Price})$$
$$R^2 = .766$$
$$T\text{-Value} = 11.31$$

700-800# Heifers (Annual Average)

$$\text{West Fargo Price} = .5080279 + (.9720322 \times \text{Kansas City Price})$$
$$R^2 = .994$$
$$T\text{-Value} = 35.844$$

Appendix C

FEEDING CONTRACT¹

This agreement, made and entered into as of this _____ day of _____, 19____, by and between _____ of _____, hereinafter called the "Grower," and _____ of _____, hereinafter called the "Feeder."

Witnesseth

Whereas, the Grower has about _____ head of _____, herein referred to as "stock," which he desired fed and finished for market; and

Whereas, the Feeder having ample resources to do so, desires to feed and finish said stock for market so that he may share in the sales proceeds thereof; and

Whereas, in order to provide for the proper care, feeding, and marketing of the stock, the Grower and the Feeder desire to appoint a supervising agent and to authorize him to supervise such care, feeding, and marketing, and to perform other related duties, all in accordance with the terms and conditions hereinafter set forth;

Now, therefore, in consideration of the premises and the mutual promises herein contained, to be kept and performed by the respective parties hereto, it is agreed by said parties as follows:

A. The Grower agrees:

1. If the stock covered hereby are mortgaged, to obtain the written consent of the mortgagee or mortgagees (which includes any assignee of any such mortgage) to this contract before the same shall become effective.

2. After giving _____ days' advance notice to the supervising agent and the Feeder, to ship to the Feeder about _____ head of feeder stock, between the _____ day of _____ 19____, and the _____ day of _____ 19____, the exact date of shipment to be at the Grower's option but within the above-described limits and to bill stock to market with stop-over enroute at _____ transit feeding yards.

3. That upon the arrival of said stock at the transit feeding yards, the supervising agent is hereby authorized and directed:

- (a) To advise the Feeder when the stock will be delivered to him so that he can be prepared to receive said stock promptly.

¹This contract form is presented solely as a suggested basic outline. It should no be used as a legal instrument until it has been checked for compliance with the laws of the appropriate state. Amendments should be considered to fit individual situations.

- (b) To take charge of said stock at transit feeding yards and feed, water, and rest the same for forty-eight (48) hours prior to weighing.
- (c) To sort off all the stock deemed undesirable by him for feeding purposes, and dispose of such off sorts according to written instructions which may be given by the Grower.
- (d) To grade the animals deemed by him to be satisfactory for feeding purposes into reasonably uniform lots of similar type, size, quality, and weight according to written specifications given by the Feeder, with the minimum weight of each animal not less than _____ pounds and the maximum weight of each animal not more than _____ pounds, and the average weight of the stock not to exceed _____ pounds, and to weigh the stock, in case of lambs, with fleeces dry, which weigh less _____ percent, shall be and is hereinafter referred to as the "contract weight."
- (e) To count the stock when he makes delivery thereof to the Feeder at the _____ transit feeding yards and obtain the Feeder's acknowledgement of receiving stock on the form attached to this contract.
- (f) To inspect said stock carefully from time to time, to make certain that the stock while in the Feeder's possession are at all times properly fed, watered, sheltered, and cared for in an efficient manner, and to make written reports promptly of each such inspection to the Grower, sending one copy to the Feeder, and retaining a copy in his files for inspection by either party hereto.
- (g) To "cut-out" or "mark-out" stock that are deemed by him to be finished for market, direct the marketing of same, and to distribute the net proceeds arising from the sale of the stock in accordance with the terms of this contract, particularly subsection 9 of section C hereof.

B. The Feeder agrees:

- 1. If the feed or pasture is mortgaged, to obtain the written consent of the mortgagee or mortgagees (which includes any assignee of any such mortgage) to this contract before the same shall become effective.
- 2. To promptly accept delivery of the stock from the supervising agent at the _____ transit feeding yards.
- 3. To set aside sufficient feed to finish the stock for market and to pasture, feed, water, shelter, and care for said stock in a proper manner at his farm located _____; all in accordance with the provisions of this agreement.

4. To pay all expenses for feed, water, shelter, veterinary service, and any necessary expenses from the time of delivery of the stock for feeding until they are reloaded for shipment to market or sold locally, and in the event of his failure to pay the same, the supervising agent is hereby authorized and directed to advance such amounts and to deduct the same with interest at the rate of _____ percent per annum, from any amounts due Feeder hereunder.

5. To permit inspection by the supervising agent and the Grower at any and all times and to follow strictly all reasonable instructions of the supervising agent with respect to the feeding, care, handling, and marketing of the stock.

C. The Grower and Feeder agree:

1. The supervising agent is hereby appointed the agent and attorney-in-fact of the Grower and the Feeder for the purpose of receiving, handling, supervising the care and feeding of, and selling the stock, and receiving and distributing the proceeds, as specified in this contract, provided, however, that the foregoing appointment and authorization, and all other undertakings and agreements in this contract contained relative to the supervising agent, shall not become effective until a supervising agent satisfactory to both Grower and Feeder has agreed in writing to act in said capacity in accordance with the terms and conditions herein set forth.

2. The title to all of said stock shall at all times during the term of this contract be and remain in the Grower free and clear of any claims, charges, costs, or expenses of the Feeder, other than as provided herein, and with no right in the Feeder to encumber or sell the stock. The Feeder shall not remove the animals from the farm or ranch without the consent of the supervising agent or the Grower.

3. Freight charges and feed expense from Grower's loading point to the feed-in-transit yards at which Feeder accepts delivery shall be advanced by the supervising agent, and the amounts so advanced, with interest at the rate of _____ percent per annum, may be deducted by the supervising agent from the proceeds of sale of the stock. Freight and feed expense so advanced shall be and remain a first lien and charge upon said stock and the proceeds of sale thereof.

4. Stock shall be fed _____ for grain feed and
(list grains)
_____ for roughage and _____ for
(list roughage) (list supplemental feeds)
supplemental feeds, in such rations as shall be prescribed by the supervising agent.

5. Any loss of stock or any damage from the crippling of stock due to the carelessness or negligence of the Feeder shall be borne by the Feeder. The amount of pounds involved in any such loss shall be computed by multiplying the average contract weight of the stock by number of stock lost, and the sum of this poundage shall be subtracted from the total number of pounds of gain obtained by the Feeder. Any loss of or damage to stock not due to the carelessness or negligence of the Feeder shall be shared--the Grower losing the average per head contract weight and the Feeder losing the feed and labor represented by his gain. The Feeder shall remove the pelts or hides showing brands, if any, of animals that have died and the same shall become the property of the Grower. Responsibility for losses and the amount thereof shall be determined in the first instance by the supervising agent provided that if either the grower or the Feeder refuses to accept such determination, the matter shall be settled by arbitration as provided in paragraph C-11 hereof.

6. The supervising agent is hereby fully authorized and empowered by the Grower and the Feeder to designate the time or times of marketing, the marketing place or places, the price or prices at which said stock shall be sold, and to sell and market said stock in his name through a bonded sales agency or to a financially responsible packing company, and to receive the sales proceeds of said stock in trust to be distributed to said parties as their interests may appear under this contract.

7. If, at any time, in the opinion of the supervising agent or the Grower, the stock is not properly cared for, either of them may serve notice on the Feeder to surrender said stock to the supervising agent or Grower; upon service of such notice, the Feeder hereby agrees to deliver said stock, in the manner provided in said notice. In any such case, either the supervising agent or the Grower is authorized:

- (a) To market said stock and make settlement for same as provided in this agreement, or
- (b) To select another party to finish the stock, in which event said stock shall be weighed on nearest scale and after deducting four percent (4%) shrink from the resulting weight, the Feeder shall be compensated for gain in weight at the rate of _____ cents per pound.

8. On any partial shipment of stock to market, the supervising agent shall withhold twenty-five percent (25%) of the net sales proceeds so as to protect all parties in the fulfillment of this contract distributing the remainder in accordance with the terms of paragraph C-9 hereof.

9. After payment of freight, marketing expenses, and supervising compensation amounting to _____ cents per head of all animals delivered to Feeder under this contract, _____ percent of the remaining proceeds shall be paid the supervising agent as full compensation for his services hereunder. The remainder of the proceeds from the sale of the stock shall be apportioned between the Grower and the Feeder on the following basis:

- (a) The Feeder shall receive the market price for the gain in weight of the stock, which weight shall be the difference between the contract and the market weight on the sale of the stock.
- (b) The Grower shall receive for the contract weight _____ cents per pound, which shall be considered to be the going market price of the feeder stock at the time this contract is executed.
- (c) Any money remaining over and above the deductions for (a) and (b) shall be divided between the Grower and Feeder on the following basis:

Seventy percent (70%) to the Grower and thirty percent (30%) to the Feeder, providing eighty-five percent (85%) or more of the stock sell at the "shipper or packer top" classification. In case the percent of stock in the "shipper or packer top" grades falls between seventy-five percent (75%) and eighty-five percent (85%), the division of the remaining proceeds shall be eighty percent (80%) to the Grower and twenty percent (20%) to the Feeder. In case less than seventy-five percent (75%) of the stock sell at the "shipper or packer top" classification, all of the remaining proceeds shall go to the Grower.

- (d) If sales proceeds are insufficient to permit a full settlement under items (a) and (b), then the difference between the amount available for distribution and the amount that would be required for making a distribution as provided in items (a) and (b) shall be considered a deficit which shall be borne by the parties on the following basis:

All of the deficit shall be borne by Grower if ninety percent (90%) of the stock sell at the "shipper or packer top" classification. If less than ninety percent (90%) of the stock and more than seventy-five percent (75%) sell at the "shipper or packer top" classification, the Grower shall stand seventy percent (70%) of the deficit and the Feeder thirty percent (30%). If less than seventy-five percent (75%) of the stock sell at the "shipper or packer top" classification, then the deficit shall be divided equally between the Grower and Feeder.

10. The terms of this contract shall be binding upon the heirs, executors, or administrators of both Grower and Feeder in like manner as upon the original parties.

11. Any disagreement arising under this contract, which the supervising agent is unable to settle in a manner acceptable to both the Grower and the Feeder shall be arbitrated by a committee of three, one member to be selected by the Grower, one by the Feeder, and the third member by the two representatives selected. The decision of any two of the arbiters shall be final and binding on all parties hereto. This shall include the naming of a new supervisor if necessary.

In witness whereof, the parties hereto have hereunto affixed their signatures the day and year first above written.
