Choice of Technique Under Price Distortions:
A Case Example of Jeopardized Agricultural Sector

by
Dr. Hassan A. Khedr

Introduction:

The point this paper is trying to make is that questions of agricultural mechanization and labor migration should not be addressed independently from the over-all incentive structure within the agricultural sector and (in a dynamic sense) the linkages between agriculture and other sectors of the economy. Empirical evidence indicates that prices in the Egyptian agriculture are subject to large distortions that manifest themselves in large discrepancies between private and social profitabilities, and between sectoral and social profitabilities.

Some comparative static analysis was adopted to test for the consistency of the pattern of protection applied to agricultural commodities. The continual practice of bias against agricultural sector and heavily taxing it via price controls has made it relevant to raise the question of how do Egyptian planners view the role of the agricultural sector.

The period of transition the Egyptian economy has experienced since the mid-seventies has presumably had an impact on the relative contribution of the agricultural sector to GNP and balance of payments.

Moreover, the substantially high rates of growth achieved in other non-agricultural sectors compared to agriculture has led to a belief from the policy makers that there is likely higher potential for development in the non-agricultural sectors.

This has resulted in continual application of measures that are biased against agriculture.

The decline in relative importance of agriculture, however, due to the existence of other balance of payments resources is not a long term condition. This argument is substantiated by the uncertainty associated with the new sources of foreign exchange earnings and their strong correlation with political considerations. The deprivation of the agricultural sector of the indogeneity of the key policy variables as well as the fragmentation of policy making attributed to the distribution of the agriculture related responsibilities among a number of ministries seems to have started a declining of the functions of the agricultural sector.

Functions and role of the agricultural sector as perceived by Egyptian economic planners will presumably be reflected in public investment policies, price incentives, and subsidy policies and should be regarded as a context for analyzing questions of choice of technique, mechanization and labor migration.

General Characteristics of the distorted Market
Structure In Egyptian Agriculture:

According to Schultz, government can intervene to alter market incentives in agriculture, in three different ways. (1) Governments may apply neutral economic policies with respect to the opportunity cost of agricultural production. Governments, on the other hand, can apply policies which either overvalue or undervalue agricultural production. Very few countries meet the first classification. Typically, however, high income developed countries overvalue agricultural products, whereas low income LDC'S undervalue them.

Egyptian agriculture is a typical case of governmental intervention. However, objectives, procedures and level of intervention vary from one crop to the other (2).

Although government intervention started in the early 1930's the idea of agriculture being a basic source to finance economic development was largely begun in the 1960's.

 - (2) Malcolm D. Bale & Ernst Lutz, "Price Distortions in Agriculture and Their Effects: An International Comparison," American Jour. of Ag. Econ., Vol. 63, No. 1, Feb., 1981, pp. 8-22.

In 1961, cotton trade was nationalized and intervention by a system of government monopolies, exchange controls, price differentials, and compulsory delivery quotas on the export crops to maintain supplies. The initiation of the public sector and the emphasis on the role of the State has affected both the agricultural and industrial sectors.

Generally for most of the crops and particularly for major field crops the market intervention was designed to maintain rural incomes by guaranteed minimum prices and at the same time to extract a surplus to pay for a consumer subsidy program to maintain urban incomes (1).

Agricultural Pricing and Subsidy Policy

Prices of major agricultural crops in Egypt are set at a relatively lower level compared to international (second best) alternatives (2). This is an indirect taxation to agricultural sector through the economic surplus transferred outside agriculture to other sectors of the economy. The method adopted for pricing is a full cost approach that presumably gives no attention to demand in the price determination.

-
- (1) Khalid Ikram, Egypt: Economic Management In a Period of transition, A World Bank Country Economic Report, the Johns Hopkins University Press, Baltimore and London, 1980. PP. 203-209.
 - (2) This is done via a higher committee that belongs to the cabinet that includes Ministers of Finance, Economy, Industry, Planning, Supply and Agriculture.

Prices of inputs and outputs are set in two parallel markets. There are the free village markets (which reflects supply-demand transactions within the village), and the marketing system through which the State Bank purchases crops and disburses inputs on behalf of the government.

Through the period 1965 - 1970 all cotton, 27 per cent of the wheat, 66 per cent of the rice and 57 per cent of the onion crop on average were delivered at prices determined by the government. Since then the list has grown to include other crops such as sesame, groundnuts, broad beans and lentils. In 1977 wheat quotas were dropped and farmers have increased the area in response to a price increment.

As an attempt to partially offset the impact of the intervention through price system the government pays some direct and indirect subsidies to the farmers. Agriculture is given a direct subsidy for pest control, fertilizers, gypsum, improved seeds, fodder, fuel oil and diesel and many minor items. Some other indirect subsidies are given to the farmers through importing some inputs at a relatively subsidized rate of foreign exchange (1).

Data of Table 1 indicate the four categories of sector specific agricultural subsidies through the period 1978-1981. These categories are input subsidies, pest control operations, and subsidies to agricultural projects. The first two groups namely the input subsidies

(1) This applies to fertilizers, pesticides, and in part to agricultural machinery.

and the pest control operations account for 96-98 percent through this period. The government does not pay a direct subsidy to mechanization, though, the low interest rates for the loans farmers get for purchasing machinery also yields a subsidy. In addition, major inputs like fuel oil, and diesel are subsidized.

Ramifications of the Agricultural Price Policy:

A Review of Relevant Literature

Under such pricing and subsidy policies in agriculture, prices lost much of their economic allocative function, as conflicting signals were sent to producers (1). The simultaneous use of many policy instruments which turned in many cases to have a net effect the converse of original objectives has led to intransparency in the price system. Attempts at corrections were conducted on partial and ad hoc bases which has led to more even confusion.

The problems of the incentive structure have manifested themselves in many forms. Unwillingness of farmers to stick to the proposed crop rotation, prices for some by-products (straw) have exceeded those of the main product, and selling inputs in the informal markets or allocating them to different crops are examples of the inefficiency of the incentive structure.

A systematic categorization of the likely ramifications of the market distortions is: 1) effects of efficiency of resource allocation and resource transfers; 2) impact on income and income distribution among sectors and within the agricultural sector; 3) effects on demand; 4) effects on supply; 5) effects on government revenues; and 6) effects on the balance of payments.

(1) Kalid Ikram, Ibid, P. 208.

Recent literature demonstrates that markets in agriculture are highly distorted. Bent Hansen (1968), Hindy (1975 & 1980), Khedr and Clark (1979), Caddihy (1980), Nassar (1978 & 1980), Ikram (1980), Korayem (1979), Ahmed Hassan (1979), Abd El Fadiel (1975), and Imara (1981) have done work that concluded that the Egyptian agricultural sector is indirectly taxed via price system. Part of this literature has confined its objectives showing the discrepancy between private and social profitabilities (1). Another part has focussed on efficiency considerations. In this respect the impact of the economic surplus transferred outside agriculture has been investigated. A third part has discussed only income distribution implications and the last part has estimated nominal and effective rates of protection for different crops. In the context of comparing private and social profitability a new line of thinking has been suggested that accordingly gives emphasis to sectoral versus social profitability (2).

Based on the above cited empirical evidence, one can argue that the agricultural sector has been subsidizing other sectors of the economy.

-
- (1) Ingram has produced some work based on the Khedr & Clark study (1979) with some modification through treating clover as a traded commodity he concluded that the ranking of the rotations has not changed from the original study: See: James C. Ingram and Tarek Moursi, "Treating Berseem as a Traded Good In the Calculation of Social Returns", ADS Project, Economic Working Paper No. 18.
 - (2) Ministry of Agriculture, Food Systems Development In Egypt, Agri-Business Seminar, Bank of America, Cairo & Misr America Inter. Bank, Dec. (7-9) Cairo, 1981.

For economists who are believers in the dualism theories of growth it might sound natural that in a developing economy like the Egyptian one agriculture should to some extent bear the burden of development. It must be noticed, nevertheless, that there is a tradeoff between developing other non-agricultural sectors and shrinkage agriculture when the surplus is large enough to affect economic efficiency and lead to a disincentivated agricultural sector.

Comparative Static Analysis: Consistency
of Protection Policy to Agricultural Products:

Since the mid-sixties the agricultural sector has based its argument for raising farm prices for major field crops on the notion of the large discrepancy between private and social profitability. The allocative repercussions of such distortions notably with respect to allocative efficiency considerations were major concern to agriculture. Surprisingly, however, this argument does not seem to be working in the process of determining farm prices.

A close look at Tables 2 and 3 would indicate the confused and confusing agricultural pricing policy and its impact on social cost of producing major crops. The domestic resource costs (DRC) in Table 2 indicate the social cost of producing four major field crops through the period 1965-1976. The social cost of producing rice and maize has been fluctuating. Conversely, the social cost of wheat and cotton were more stable in their pattern since the DRC analysis has shown cotton to be socially inexpensive to grow and wheat to be socially expensive over the period.

Nominal and effective rates of protection have been calculated for the same commodities through the period 1965-1976 as shown in Table 3. The partial and ad hoc domestic pricing policy was

$$N = \text{Nominal Rate of Protection for the } i \text{ th commodity} = \frac{P_{i,d}}{P_{i,b}} \quad \begin{array}{l} 1 = \text{Subsidy} \\ 1 = \text{Tax} \end{array}$$

Where:

$P_{i,d}$ = domestic farm-gate price of the i th Commodity.

$P_{i,b}$ = Border price of the i th commodity, being the foreign price X the official rate of exchange adjusted for internal trade and transport margins to the farm-gate with further adjustments for processing equivalence.

$$E = \text{effective rate of protection for the } i \text{ th Commodity} = \frac{Va_{i,d}}{Va_{i,b}}$$

Where:

$Va_{i,d}$, $Va_{i,b}$ = Value added in the i th activity at domestic and at border price with adjustments for equivalence to the farm gate.

inconsistent as well, and did not show any particular pattern of protection either in the nominal or in the effective sense.

The continual use of price and subsidy policies independently as two inconsistent policy instruments has led the economy to go back and forth between subsidizing and taxing crops.

Khedr and Clark of 1979 did some calculations and comparisons of private social profitabilities for nine different crop rotations (1). Economic surplus transferred from agriculture was calculated.

Similar analysis was conducted here using the 1980 and 1981 data. The analysis was done with the objective of comparing private and social profitabilities which may give in a comparative static sense some indication about the direction of the discrepancy. This consequently can answer a lot of questions related to efficiency and equity. Furthermore, it can give some idea about the government budget implications of the pricing and taxation policies within the agricultural sector.

Comparisons of the economic surplus transferred from agriculture to the other sectors of the economy in the three years indicate that it has increased for almost all rotations between 1979 and 1980. It has decreased, however, in 1981 in view of raising the farm prices of some crops and in view of raising the agricultural subsidies which increased from about L.E. 65 million 1979 to about L.E.145 million in 1980 and then to L.E 158 million in 1981.

A closer look back to the data of Table 4 shows a change in the economic surplus in ways favoring clover rotations; clover + cotton; clover + rice; clover + soybeans + nili maize; and clover + maze. Rotations of wheat, namely wheat + rice and wheat + maize

became unfavorable to the farmers in 1981.

Role of Agriculture As Viewed by Egyptian Planners

In A Period of Transition:

The question of how Egyptian planners view agriculture is becoming extremely important. Key agricultural policy decisions are made exogenously (1).

The data of Table 5 indicate some structural changes that have occurred in the Egyptian economy through the last two decades. The relative share of agriculture in the national income, agricultural exports, imports and investments as percentages of the national equivalents have undergone dramatic changes through the period 1960-1979.

-
- (1) The Ministry of Agriculture does not have final say about farm prices of major crops. Agricultural labor is not something which the MOA gives emphasis to in terms of studies, data and for coordination with other Ministries. The coordination between Ministries of Agriculture and Irrigation is not as high as should be. Irrigation and drainage programs should be much more efficiently coordinated within the agricultural sector. Plans regarding land reclamation and rehabilitation are the responsibility of another distinct ministry. There must be joint planning, because prices of inputs or outputs, supply and demand for a particular product should not be distinguished on the basis of old vs. new lands. The subsidy policy for the consuming sector is done in the Ministry of Supplies. The determination of prices and subsidies at the consumer level would presumably feed back to their equivalents at the farm level, notably with respect to nontraditional crops. The MOA has been assigned the title of Ministry of State for Agriculture and Food Security. The Ministry is not doing much as far as Food Security, and being a Ministry of State would confine its functions to extension and research.

Table 5

* Previous data are in real terms.

Source: The National Bank of Egypt, The Economic Bulletin, Cairo
(different issues).

The agricultural income as a percentage of the national income has decreased from 29.5% in 1960 to 20% in 1979. The share of agricultural exports from the total exports has diminished from 85.4% to 49.6% through the same period. Moreover, the share of agricultural investment of the total investments has fallen from 16.9% to 7.9%.

Since mid seventies some liberalization measures have been adopted. This has not been meant to withdraw the state from active intervention. There was no radical change, but certainly there was a redefinition of priorities and a series of cumulative changes which finally became a major change (1). The opening of the economy since 1974 has been accompanied by a large gross capital inflow (2).

Rates of change of GSP, National Consumption
and Gross Investments

Data in Table 6 show some comparisons of some macro-variables indicating the structural changes that have occurred in the Egyptian economy through the period 1970-1979.

• Data of the previous table indicate the following:

A) There are new sources of foreign exchange earnings which have increased dramatically since 1974.

B) Most of these sources are for services, such as workers remittances, tourism, Suez Canal and shipping.

C) Comparison of percentage rates of growth before and after 1974 shows that the rates which have been achieved before 1974, increased dramatically after 1974, notably with respect to worker remittances and tourism.

Choice of Technique Under Market distortions

Previous analysis indicates that the significance of the agricultural sector has been changing in the minds of the policy makers.

Egyptian agriculture is a typical example of a price distorted market. The distortions are not only disfavoring agriculture but they are also inconsistent. Nominal and effective rates of protection did not show a consistent pattern of protecting major field crops.

Moreover, in view of some structural changes in the Egyptian economy following 1974, the relative importance of agriculture has been deteriorating in the minds of Egyptian planners.

In the light of these facts, one could argue that the question of choice of technique as an optimization question would be very difficult to address. Prices of neither inputs nor outputs are efficient indicators reflecting relative scarcities of inputs. With relatively highly subsidized capital compared to labor, allocative inefficiency then occurs. Appropriate technology in this world would be one which seeks technical convenience.

Some economists, however, would argue that in a price distorted world where first best solutions are non-existent, one should, for practical considerations, look to international prices to indicate a second best solution. Decisions related to choice of technique could be made from border prices for exports and import substitutes.

If we accept to talk about so-called appropriate technology in a distorted world this should be tempered with the awareness of the quality of recommendations we are suggesting. These suggestions one would argue should be taken as very rough indicators. Since there is no reason to believe that all international FOB or CIF prices are necessarily Pareto Optimal.

Issues like choice of labor vs. capital intensive techniques, mechanization and agricultural labor migration should not be addressed independently of the whole issue of the incentive structure in agriculture.

The GDP at constant factor prices (1975) has increased from L.E. 4005 million in 1970/71 to L.E. 7065 million in 1979. Average annual rate of growth before 1974 was 3.5% which has drastically increased to 9.5% following 1974. The breakdown of GDP by sector and calculating the average annual rate of growth for the five years before and after 1974 shows a drastic change specially in the petroleum, construction, distribution, electricity and industrial sectors. The rate of growth, however, achieved in agriculture was relatively low.

The change was not only confined to GDP. Drastic changes have occurred in the national consumption and gross investments before and after 1974. Average annual rate growth of consumption has increased from 7.8% over the period 1970-74 to 18.6% over the period 1974-78. Public investments, on the other hand, space needed have expanded with

an average annual rate of growth of 15.2% over the period 1974-78 which has jumped to 42.8% through the period 1974-78.

Rates of Change of Balance of Payments Current Account Components:

Data of Table 7 present some indicators about the structural change of the components of the current account of the balance of payments before and after 1974. These comparisons presumably give indications about the degree of openness of the economy and the relative significance of each item in the composition of the current account.

Table 7

Balance of payments current account in Egypt 1971 - 1979

- Assumptions : 1- Prices and Production is of 1980 except . for Wheat - Beans - Onions - Lentils its was for 1981 - 82 .
- 2- Summer and Mili Potatoes labor cost has been increased by 30% in 1981 compared to 1980 . Same increment was applied to cost of fertilizers .
- 3- Cost of production for wheat, Lentils, Beans , Onion , T. Clover and P. Clover has Been increased by L.E. 5 , 8 , 12, 14,5 , and 8 respectively Compared to those of 1981 .

9) Wheat + Maize	89.800	284.630	3.170	194.830
10) Brood Bean + Maize	133.550	377.150	2.820	243.600
11) Broad bead + Rice	133.400	349.670	2.620	216.270
12) P. Clover + Maize	74.630	181.350	2.420	106.720
13) P. Clover + Rice	177.200	338.140	1.910	160.940
	118.430	169.820	1.430	51.390

- (1) The Crop Rotations are ranked according to the ratio
(N.R.E / N.R.F).
- (2) N.R.F: Net Revenue to the farmers.
- (3) N.R.E: Net Revenue to the Economy.

Table 5

Economic Surplus, Private and Social
Profitabilities of different Rotations 1977 & 1981

Crop Rotation	Private and Social Profitabilit,	1977 (L.E.)	1981 (L.E.)
1) T. Clover + Cotton	Private P. Social P.	131 441	301 755
2) T. Clover + Soy bean + Nili Maize	Private P. Social P.	170 200	236 302
3) P. Clover + Maize	Private P. Social P.	210 262	378 415
4) Wheat + Maize	Private P. Social P.	138 240	134 249
5) Wheat + Rice	Private P. Social P.	117 535	83 384
6) Broad bean + Maize	Private P. Social P.	98 (299)	198 365
7) P. Clover + Rice	Private P. Social P.	169 557	328 550
