Family Farms and Farming Families: The Overlap of Two Institutions

Ray D. Bollman (Ray.Bollman@statcan.ca) Agriculture Division, Statistics Canada, Ottawa, Canada K1A 0T6

Paper presented to the EAAE Seminar on Institutional Units in Agriculture, Wye Campus of Imperial College, Ashford, Kent, UK, April 9-10, 2005

Introduction

Farms and families are the two core institutions in primary agriculture. Surprisingly to some, family farms and farming families – the overlap of farms and families – continue as the core institutional structure in primary agriculture. The purpose of this paper is to document the various dimensions and contributions of family farms and farming families to agriculture in Canada.

Family farms – their number and their share of farm production.

The 2001 Canadian Census of Agriculture enumerated 246,925 census-farms (Figure 1). A census-farm is any agricultural holding with some agricultural products for sale. In 2001, 22 percent of Canadian census-farms generated less than \$10,000 of gross farm revenue and 53 percent generated less than \$50,000 gross farm revenue. Note that this structure differs significantly from the structure of census-farms in the USA where about one-half of USA censusfarms generate less than \$10,000 gross farm revenue, compared to about one-quarter in Canada (Whitener et al., 1995).

Among the 246,925 census-farms enumerated in the 2001 Census of Agriculture, 241,940 census-farms (98 percent of the total) were "family farms" (Table 1). Specifically, these farms were identified with one of the following types of legal organization:

- Proprietorship
- Unwritten partnership
- Written partnership
- Family corporation.

The remaining farms were non-family corporate holdings or other types of farms, including institutional farms, co-operative farms, estate farms, Hutterite Colonies, etc.

"Family farms" generated a vast majority of agricultural production in 2000 – fully, 88 percent of aggregate gross farm revenue was generated by these farms. However, their contribution to various types of commodity production varied – from a high of 96 percent of the production of commodities such as wheat, corn for grain and milk to a 'low' of 79 percent for pigs (Table 2).

We acknowledge that various contractual relationships may tie the production of so-called "family farms" into various corporate bodies in the value-chain of the given commodity – in this sense, the independence of the family farm decision-makers may be less than is suggested by a simple count of the quantity of agricultural production on census-farms classified as "family farms."

Nevertheless, in 2001, the vast majority of census-farms in Canada were operated by farming families and they were associated with the vast majority of production of major agricultural commodities in Canada.

The contribution of one-household – one-farm holdings

Another way to document the overlap of families and farms in primary agriculture is to investigate the household structure associated with census-farms. We look specifically at the number of households associated with each census-farm. Since 1991, the Canadian Census of Agriculture has permitted up to three "operators" (defined as persons involved in the day-to-day management decisions of the agricultural holding) to be identified for each census-farm. In 2001, 229,970 census-farms (93 percent of the total) (Figure 2) were operated by operators living in one household. Among the remaining census-farms, 14,410 (6 percent) were operated by operators living in two households and 2,545 (1 percent) were operated by three (or more) operators living in three different households. Note, however, that only 153,730 census-farms (62 percent) were operated by one operator.

In 2001, 84 percent of the aggregate gross farm revenue in Canada was generated by census-farms with all (one or more) operators residing in a single household (Figure 3). The converse is that 16 percent of aggregate gross farm revenue does not comply with the one-household – one-farm overlap of farms and families in agriculture. Note also that only 59 percent

aggregate gross revenue was generated by one-operator census-farms – fully 41 percent of aggregate gross revenue was generated by census-farms with more than one operator.

Thus, from this dimension also, we see that a vast majority of census-farms and a vast majority of agricultural production is associated with the one-household – one-farm model.

Some commodities are less likely to be produced on census-farms where their (one or more) operators are living in one household. Census-farms where the operators live in two or three households produce a significant share of the following commodities:

- potatoes (34 percent);
- > milk (23 percent);
- > corn for grain (28 percent); and
- greenhouse products (21 percent) (Table 3).

Another dimension of the nexus of family farms and farming families is the role of gender in understanding the operating structure of farms. A look at the number of census-farms according to the gender mix of operators reveals:

- For census-farms with one operator, 92 percent are male and 8 percent are female (Table 4);
- For census-farms with two operators,:
 - 77 percent have a male/female operator structure and 99 percent of these cases involve the two operators living in the same household;
 - an additional 14 percent have a male/male operator structure where 74 percent of the cases involve two households and only 26 percent of the cases involve the two males living in the same household;
- For census-farms with three operators:
 - the modal group (41 percent of the census-farms) is a male/female/male operator structure. Slightly over half (52 percent) are situations where all three operators live in the same household. Most of the other cases (47 percent) are situations where the three operators live in two households and a few cases (less than 2 percent) are cases where the three operators reside in three separate households;
 - the second largest group (30 percent of three-operator census-farms) have an operator structure that is male/male/male. In 70 percent of these cases, the three male operators live in three separate households.
- The involvement of females in the operation of Canadian census-farms sorts out as follows:
 - o 64,045 census-farms (26 percent) have a male/female operator structure:
 - o 11,880 census-farms (5 percent) have a sole female operator;
 - 6,420 census-farms (3 percent) have a female/male operator structure;
 - 4,165 census-farms (2 percent) have a male/female/male operator structure;
 - 1,595 census farms (1 percent) have a male/male/female operator structure;
 - o 735 census-farms have a male/female/female operator structure;
 - 485 census-farms have a female/female operator structure;
 - o 445 census-farms have a female/male/male operator structure;

- o 170 census-farms have a female/female/female operator structure;
- o 85 census-farms have a female/female/male operator structure; and
- o 50 census farms have a female/female/female operator structure.

Overall, about 63 percent of Canadian census-farms have only male operators (57 percent with one male operator; 5 percent with two male operators; and 1 percent with 3 male operators). Thus, over one-third (37 percent) of census-farms have a female operator participating in the day-to-day management decisions of the census-farm.

Another dimension of the overlap of family and farms is the mix of generations among operators. In 2001, 62 percent of the census-farms had one operator, 30 percent had two operators of the same generation and an additional 1 percent had three operators of the same generation (Table 5). Thus, 93 percent of all census-farms had operators of the same generation and only 7 percent had operators from two generations that were involved in the day-to-day management decision-making on the census-farm. Among census-farms operated by operators of different generations:

- 8,170 census-farms (3 percent) were two-operator farms with operators of different generations. For these census-farms, 41 percent of the census-farms had the two operators living in the same household and 59 percent of the census-farms had the two operators living in different households.
- 4,810 census-farms (2 percent) were three-operator farms where the 1st and 3rd operator and the 2nd and the 3rd operators were from different generations. For these censusfarms, in 53 percent of the cases, all three operators lived in the same household, 39 percent were two-household arrangements and in 8 percent of the cases, the three operators lived in three households.

The income relationship between farm firms and farming households

Agricultural policy is often justified on the basis of increasing the income of farming households. However, agricultural policy flows to farms. How does the income of farms flow to the farming families? What is the income relationship of farm firms and farming households?

The first probability survey of farms in Canada was the omnibus 1958 Farm Survey. The lengthy questionnaire documented farm receipts by source, farm expenses by item, household revenue by source and household expenses by item. When the results were (finally) published, the data referred to only 93 percent of the farms because the remaining units did not have the simple one-household – one-farm structure that had been the traditional form of family farms in Canada (Dominion Bureau of Statistics, 1962; Fitzpatrick and Parker, 1965; Fitzpatrick, 1967).

Mitura and Di Piétro recently estimated the potential impact on farm family incomes due to the closure of the USA border to cattle exports from Canada (due to the discovery of one case of BSE in May, 2003). Due to the nature of the database¹, their analysis was constrained to

¹ See the Appendix on "Data Sources and Methodology" in Statistics Canada (2005) pp. 52 – 57.

Statistics Canada Statistique Canada census-families² associated with unincorporated beef cattle farms operated by an operator who was a member of a census-family and who was involved in only one farming operation. The point for this paper is that the constraints of the database permitted the analysis to discuss the income of families associated with only 37 percent of the aggregate gross revenue from beef cattle sales (Table 6). Specifically,

- although only 2 percent of beef cattle farms were excluded because they were incorporated, they represent 36 percent of the aggregate gross revenue from the sale of beef cattle;
- in addition, individuals associated with an additional 13 percent of beef cattle farms (representing 13 percent of aggregate beef cattle sales) were excluded because the operator was not a member of a census-family or the members of the census-family were involved in more than one farming operation.

Generating an estimate of the income of the farming family for families associated with corporate farms is problematic in some databases. Specifically, individuals receive income from corporations either in the form of wages or in the form of dividends. In some databases, these income sources 'appear as' off-farm income sources. For Statistics Canada's Agriculture-Population Linkage database³, Ehrensaft and Bollman (1992) (see also Bollman and Ehrensaft (1990) and Fuller and Bollman (1990)) estimated the amount of wages received by the farming family from the farm corporation in order to estimate "agricultural income" received by the farming family and "non-agricultural" income received by the farming family. For families of the operator of census-farms with gross farm revenue above \$563,550 in 1985 (the top 1 percent of census-farms in the 1986 Census of Agriculture), the adjustment to calculate an "agricultural income" resulted in the following adjustments for census-farm operator families of farms in the top percentile:

- reported unincorporated net farm income of \$25,550 was boosted by \$13,852 of estimated "agricultural wages" paid from farming corporations to farm family members; and
- 2. reported family investment income of \$6,480 was estimated to be \$4,145 from the farm corporation and \$2,335 from non-farm investments.

³ Statistics Canada's Agriculture-Population Linkage database is generated from a micro-record linkage of the Census of Agriculture questionnaire and the Census of Population questionnaire. This is facilitated in the Canadian case because the two census questionnaires are dropped off at the household of each farming family on Census Day. The result is a database of the characteristics of the census-farm that can be cross-tabulated with the socio-economic characteristics of each member of the family of the census-farm operator. In 1986, there were 293,089 census-farms. The calculations by Ehrensaft and Bollman (1992) (also see Bollman and Ehrensaft (1990) and Bollman and Fuller (1990)) excluded the families of operators of institutional farms, community pastures, non-family corporations, Hutterite colonies and miscellaneous types of farms such as estates and trusts. Also excluded were unmarried operators and families with more than operator (which implies that, since only one operator was identified for each census-farm in the 1986 Census of Agriculture, families were excluded if they were associated with two or more census-farms). The resulting analysis of the family income for census-farm operator families referred to 259,200 families – thus, individuals associated with 33,869 census-farms (12 percent of all census-farms) were excluded from the analysis.

Statistics Statistics Canada Ca

² A census-family is a husband and wife, including children of any age if present in the household, plus a lone-parent with children.

3. Consequently, the estimated share of family income generated by the farm for families associated with the top 1 percent of census-farms was adjusted from 39 percent to a more reasonable 67 percent of family income being generated from farming activities.

Consequently, documenting the flow of farming income to the associated farming family is not straight-forward.

Here, we summarize (in Text Table A) some aspects of the flow of farming income to the associated farming family.

First, we see that for one-operator proprietorship farms:

- They represent 48 percent of all census-farms;
- They generate 24 percent of all gross farm revenue; and
- The receive 20 percent of all net farm cash revenue.

Thus, if aggregate net farm cash revenue increased by \$1, on average, one-operator proprietorship farms would receive 20 cents.

Second, we see for all unincorporated census-farms where all the operators live in one-household:

- They represent 86 percent of all census-farms;
- They generate 54 percent of all gross farm revenue; and
- They receive 50 percent of all net farm cash revenue.

To make the same argument, if aggregate net farm cash revenue increased by \$1, on average, the households associated with these farms would receive 54 cents. Thus, less than one-half of Canada's agricultural production is generated by unincorporated census-farms.

For some data analyses, the database constrains the analysis to the unincorporated sector (for example, Mitura and Di Piétro, 2004). For other analyses, in order to include the households associated with incorporated farms, one needs to make 'crude' adjustments to gain an understanding of the ratio of farm-generated income versus off-farm income received by the household of the census-farm operator (for example, Ehrensaft and Bollman, 1992). Thus, the type of legal organization of the census-farm influences our ability to generate the split of household income between farm versus off-farm income. This is problematic for most Canadian sources for farm household income data, the income is reported as received by the household – specifically, as unincorporated self-employment net farm income, wages and salaries (whether from a wholly-owned family farm corporation or from off-farm employment), dividends (whether from a wholly-owned family farm corporation or from off-farm investments) plus the usual other sources such as the net income of a non-farm business, pensions, government transfer income, etc.

Third, we see for all the households associated with family farms:

- They represent 98 percent of all census-farms;
- > They generate 88 percent of all gross farm revenue; and
- They receive 87 percent of all net farm cash revenue.

If aggregate net farm cash revenue increase by \$1, on average, 87 cents would flow to family farms and 13 cents would flow to non-family farms.

Two other aspects are summarized in Text Table A. The distribution of cash wages paid by the census-farm to family members indicates, not surprisingly, that 95 percent is paid by family farms. Also, not surprising, 55 percent of the total is paid by family corporations as this is one way (dividends being the other way) that revenue generated by the corporate census-farm is flowed to the farming family. We also see the distribution of the amount of family labour (whether self-employed work or paid work or unpaid family work) contributed to by the census-farm operator household to the census-farm. Again, not surprisingly, 96 percent of the agricultural labour contributed by census-farm operator households is work on family farms. Note the relatively large share (36 percent of total family labour in agriculture) is worked on one-operator proprietorship farms. This is largely the work of the operator.

When all is said and done, we can look at the average income from all sources for the household, regardless of how the income is flowed from the farm to the household. The income from all (farm plus off-farm) sources for the average household with a farm operator present was \$61,609 in 2000 (Table 12). Note that Table 12 presents the income per household, not the income per census-farm. We see that households associated with the one-operator proprietorship farm have average income from all sources that is 7 percent below the level of all census-farm operator households. Households associated with incorporated family census-farms have average income from all sources that is 14 percent above the level of all census-farm operator households.

Discussion and implications

There are a number of reasons for documenting the inter-relationships of farms and households in Canadian agriculture:

- First, to understand the elasticity of response of commodity production to price change and to policy change, it is important to understand the decision-making structure of Canadian agriculture.
- Second, since the labour of self-employed farm operators still provides the bulk of the labour in Canadian agriculture, it is important to understand the operator structure of Canadian agriculture.
- Finally, for a statistical agency who wishes to enumerate the size and change of agricultural production on census-farms, it is important to know the operator structure and the household structure of agricultural production. What is the probability that the same agricultural holding is enumerated twice if a questionnaire was sent to each household associated with an agricultural holding? The advertisement for the Canadian

Statistics Statistique Canada Canada Census of Population (and recall that the Census of Agriculture is enumerated by the same enumerator on the same "Census Day") is "Count yourself in". Obviously, conscientious citizens will ensure that they respond conscientiously. Carlyle (1994) found that the Census of Agriculture actually over-enumerated some aspects of Canadian agriculture because each operator on some census-farms completed a Census of Agriculture questionnaire in order to respond to the requirement to "Count yourself in". Since the Census of Agriculture is enumerated by knocking on the door of households of the operators of census-farms, there is an obvious and important head office process to remove duplicate census questionnaires for the same census-farm.

The findings indicate that:

- 62 percent of census-farms, representing 59 percent of gross farm revenue, are operated by one operator;
- 93 percent of census-farms, representing 84 percent of gross farm revenue, are operated by individuals living in one household;
- female operators are involved in the operation of 37 percent of the census-farms;
- only 7 percent of the census-farms have operators from 2 generations, but at least onefifth of these "different-generation" operators reside in the same household.

Thus, although the dimensions of farms, operators and households overlap in various ways, in general, for purposes of understanding:

- the elasticity of production response;
- the labour contribution of operators; and
- the target for agricultural surveys

the strong modal group of census-farms remains the one-household – one farm operation.

Summary and conclusions

The rhetoric of the demise of the family farm suggests that agricultural production units in developed countries have evolved a considerable distance from the one-household – one-farm structure. Certainly, today, many operating units (that look and feel like a farm) often have individuals from more than one family involved in the operating structure and sometimes have more than one business firm that are involved in various aspects of the so-called farming operation. For all commodities included in this paper, a majority of the production is managed by (one or more) operators living within one household. However, for some commodities, over 20 percent of the production (and 34 percent in the case of potatoes) is managed my operators living in two or three households. Thus, management decision-making in response to price and other exogenous shocks would be expected to more complex and managers of agricultural surveys need to be careful that only one household gets the survey questionnaire for the given farm.

However, the one-operator proprietorship farm represents less than one-half of Canadian census-farms and less than one-quarter of farming revenue. Thus, a significant share of census-farms and a significant share of agricultural production come from unincorporated partnership

Statistics Canada Statistique Canada farms and from incorporated family farms. Family farms, overall, represent 98 percent of censusfarms and 87 percent of net farm cash revenue.

Finally, 93 percent of census-farms are managed by operators living within one household – which is exactly the same share as in 1958. However, for some commodities, like potatoes, one-third of the production is managed by operators living in two or more households.
