A Disaggregated Exports  
Forecasting Model for Taiwan

## I. Introduction

This paper supplies a detailed econometric model with the purpose of forecasting the future of Taiwan's exports up to the year 2000.

Main characteristics of the model are as follows:

- (1) The INFORUM-type I-O model forms the backbone of this trade model;
- (2) The Almon function is used for estimation;
- (3) Linkage to four of Taiwan's major trading partners is provided;
- (4) While the I-O model has 76 sectors, only 61 sectors are related to trade.

However, a corresponding table between these I-O sectors and the SITC code, up to four digits, is provided so that the relation to the common trade classification can easily be traced back.

A short description of the whole INFORUM-type model follows in the next section. The structure of the trade model is then introduced in Section III, and in Section IV all empirical results, except forecasting, are presented. 12 forecast scenarios are given in Section V.

## II. The INFORUM-type Interindustry Econometric Model

The INFORUM-type model is an econometric model that takes into consideration the I-O transaction accounts. There are two major parts of such a model: a real-side model and a price-income-side model. These distinguish whether value-

added items are taken into consideration. If no value-added is excluded, the model has only the real side. If value-added is included, the model is completed with the price-income side.

The inclusion of value-added items would make, among other variables, GNP and, correspondingly, disposable income endogenous. This poses considerable complications to the model. Because of this, most INFORUM models still have only the real-side structure. This is the model we are going to introduce below.

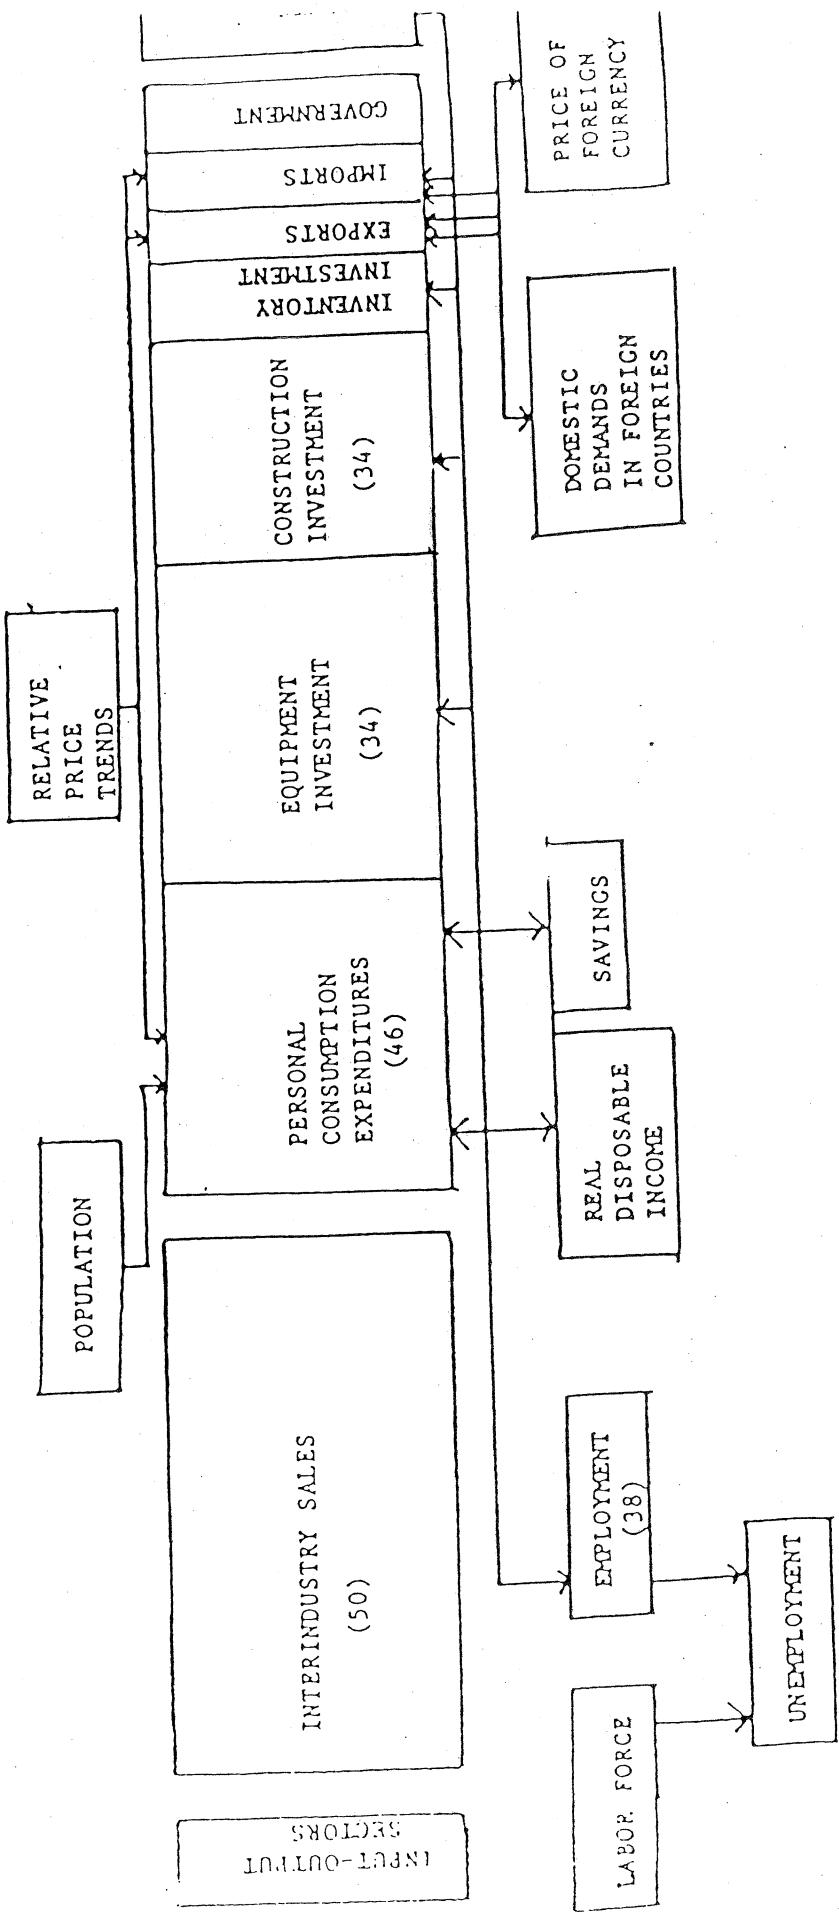

The skeleton of the model is best displayed in a figure, like the one given in Nyhus (1981), we reproduce it here in Figure 1.

Starting with some exogeneous variables, such as population, prices, disposable income, savings and foreign demand, one can solve for the values of final demand items. Complications may arise because some categories of final demand are functions of industrial outputs, while the output itself is composed of final and intermediate demand. If the model is well developed, however, output and final demand can be simultaneously solved, and consequently the solution for intermediate demand is trivial.

The final step of the model is then to calculate the value of employment or unemployment as affected by the level of output.

In general, each category of final demand should be made as disaggregated as the I-O sectors. However, final demand data in I-O classification form are usually not abundant enough to form a time series long enough for econometric

FIGURE 1. THE INFORUM-TYPE INTERINDUSTRY ECONOMETRIC MODEL

SOURCE : NYHUS (1981) , P.4

use. Thus, we resort to national account data. In this case, one has to sacrifice the requirement of having the I-O sectors. A way to amend this shortcoming is to use a bridge matrix. Ideally, we need many bridge matrices, one for each category of final demand each year. In reality, however, this is impractical, at least in view of the cost that might be incurred. Usually, a bridge matrix of one (base) year is used for all.

A completed INFORUM-type model would involve more problems and, correspondingly, more assumptions and techniques to solve them. For example, the problem of coefficient change. We refer interested readers to such works as Almon, et al. (1966, 1974) and Nyhus (1981, 1983) for more information. In the meantime, we shall return to the trade sub-model.

### III. The Structure of the Trade Model

Although trade is part of the INFORUM model, we treat exports as an independent sub-model. Theoretically, this is not incorrect because exports are not a function of any domestic variable. Thus no problem of feedback or simultaneity would arise. On the other hand, it is generally assumed that exports create domestic income to full extent. This means that calculation of the impact of exports on GNP is redundant.

The model is displayed in Figure 2. Each of Taiwan's export sectors is assumed to be a function of relative prices and foreign demand. Foreign demand is an aggregate concept. It is formed by the domestic demand of the four major trading partners and is influenced by the level of world exports. World exports in SITC groups is assumed to have a single relation with world exports in total.

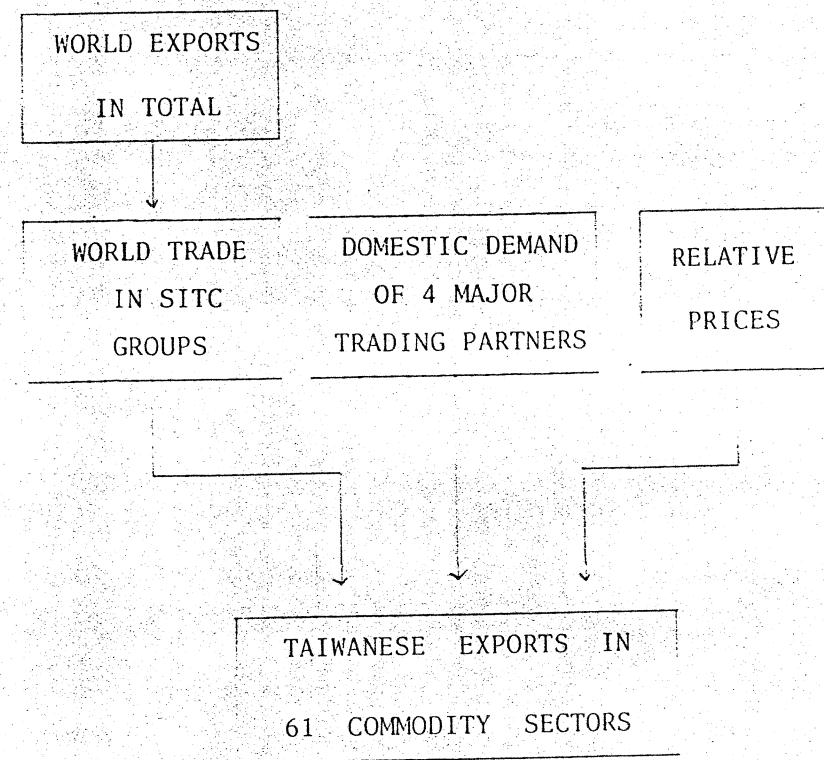

Figure 2. The Trade Sub-model

A description of each variable is given below.

### III.1 Relative Prices

The relative price is the ratio of domestic price to foreign price in the same sector. In this model the export price is used as the domestic price. The data on export price are not complete; it stops after 1977, although data for exports range from 1961 to 1982.

Fortunately, we have domestic wholesale price data from national accounts. After careful scrutiny, we find a close relationship between these two sets of data in the overlapping time interval. Projection of export prices from 1978 to 1982 is made using simple regression without logarithms, and with the help of a bridge matrix.

The foreign price is adopted from the INFORUM U.S. model.

Relative prices are formed from these two sets of price data. Based on the hypothesis, as formulated by Junz ad Rhomberg (1973), that the impact of relative price on trade flows is not fully reflected until years later, we consider, therefore, price variables with up to a five-year lag. However, instead of estimating the lag variables themselves, we have adapted the coefficients of these variables from the U.S. model. Using these coefficients as weights, we then calculate a new time series of relative prices.

Symbollically, this is equivalent to saying that instead of estimating the following assumed equation:

$$(1) \quad X_t = a + b_1 \cdot p_t + b_2 \cdot p_{t-1} + \dots + b_6 \cdot p_{t-5} + c \cdot Y_t,$$

where  $X_t$  is the export flow,

$p_t$  is the price in t-period, and

$Y_t$  represents any other explanatory variable,

We calculate the following new variable:

$$(2) \quad P_t' = d_1 \cdot p_t + d_2 \cdot p_{t-1} + \dots + d_6 \cdot p_{t-5},$$

where

$$d_i = b_i / \sum b_j, \quad \text{for all } i,$$

and use this new variable to explain the trade flow, i.e.,

$$(3) \quad X_t = a + e \cdot P_t' + c \cdot Y_t.$$

If the weights are correctly given, Equations (1) and (3) should lead to identical estimation results.

The corresponding weights used for each sector in the model are listed in Appendix A.

### III.2 Foreign Demand

An index of foreign demand for Taiwan's exports is made according to

the following formula:

$$(4) FDM_i = w_{1i} \cdot DD_{usi} + w_{2i} \cdot DD_{Ji} + w_{3i} \cdot DD_{ci} + w_{4i} \cdot DD_{ei} + w_{5i} \cdot DD_{ri},$$

where  $FDM_i$  is the foreign demand of the  $i$ th sector,

$DD_{usi}$  is the domestic demand in USA,

$DD_{Ji}$  is that in Japan,

$DD_{ci}$  is that in Canada,

$DD_{ei}$  is that in the EEC,

$DD_{ri}$  is that in the rest of the world, and

$w_{ki}$ 's are the weights attached to these countries (regions).

Weights are the export shares to these regions in the base year (1979).

The assumption of constant weights over all the years is just for computational convenience.

The EEC component should be clarified further. The weight attached to it is Taiwan's export share to the 9 EEC countries plus Australia and New Zealand, while the index of domestic demand is approximated by the German data. Although INFORUM does have an index for almost every EEC country, we justify the use of only one country's index on the grounds that Germany absorbs about half of all of Taiwan's exports to the EEC, and that countries of these groups (the EEC countries, New Zealand and Australia) are at a similar level of industrialization.

Some interesting phenomena can be observed from the export share table which is given in Appendix B. For example, while most of the paddy rice goes to the rest of the world, the USA absorbs about 74% of other crops from Taiwan.

The USA is also the largest market for the following products from Taiwan:

- Sector 4 -- Crops for processing (44%)
- Sector 5 -- Horticultural crops (56%)
- Sector 19 -- Tobacco & alcoholic beverages (91%)
- Sector 23 -- Non-alcoholic beverages (96%)
- Sector 34 -- Pulp, paper & paper products (46%)
- Sector 40 -- Plastics & plastic products (49%)
- Sector 46 -- Cement products (65%)
- Sector 55 -- Household electrical applicances (58%)

It is also interesting to note that, while the USA absorbs most of the cement products from Taiwan, Japan takes most of the cement (as material, 99%).

Other important products exported to Japan are:

- Sector 26 -- Artificial fibers
- Sector 27 -- Artificial fabrics
- Sector 47 -- Glass
- Sector 50 -- Steel & Iron products
- Sector 54 -- Machinery
- Sector 56 -- Communication equipment, and
- Sector 58 -- Ship-building materials and ships

We assume that the demand for the exports to the rest of the world can be represented by the index of world exports. We assume, to generate future data on world exports in disaggregated sectors, that they are log functions of the world exports in total. Since each has its own function, they can have different growth patterns, despite the single movement of world trade in total.

Since future values of other domestic demands are adapted directly from the corresponding country models of INFORUM, the only room left for maneuver is the manipulation of world trade in total. This is the background of most of the scenarios of forecasting to be discussed in Section V. Since different country models use different I-O sector classifications, various conversion tables are developed. In doing this, we assume equal weights for disaggregation. Tables of SITC group names and conversion tables from these groups to I-O sectors are given in Appendix C.

#### IV. Empirical Results

As explained above, our export flow is a function of two variables: relative price and foreign demand. The functional form we use is the Almon function (See Almon (1979)), i.e.,

$$(5) \quad S_i = (a + b \cdot Y_{fi}) \cdot (P_d/P_f)_i^c,$$

where  $X_i$  is the exports of Sector  $i$ ,

$Y_{fi}$  is the foreign demand index, and

$(P_d/P_f)_i$  is the relative price index.

The rationals behind our preference for this function over the commonly used CES-derived function is stated in Almon, et al. (1974, p. 125): "the elasticity with respect to domestic demand ... frequently turns out to be larger than 1.0, sometimes as high as 3.0. ... If (imports) already supply 30% of domestic demand (in the base year), (a doubling of domestic demand would mean) a 120 percent of import share (in the next period)."

Although this statement is more an empirical rectification than a theoretical reason, we retain the use of Equation (5). However, this equation is non-linear in parameters. Estimation will be much simplified if a correct start value of  $c$  is given. Thus the CES-derived demand function is still useful, in that it provides an a priori coefficient,  $c$ , for estimating Equation (5), and in that it serves as basis for comparison with Equation (5). The CES-derived demand function for exports has the following form:

$$(6) \quad X_i = a(Y_{fi})^b (P_d/P_{f_i})^c.$$

Detailed estimation procedure can be found in Almon, et al. (1974, p. 126). Estimated results are reported in Appendix D, where four tables are given. In Table D.1, we estimate Equation (6) with the price variable unadjusted; in Table D.2, Equation (6) is estimated with the adjusted price variable as explained in Section III.1; Table D.3 gives the results of the estimation of Equation (5) without a priori price elasticities; and Table D.4 gives the results of those with a priori price elasticities from Table D.2.

#### IV.1 The Data

Unpublished data on exports have been supplied by the council of Economic Planning and Development directly, with the kind permission of K.C. Lee and J.C. Chao. Some macro data, like wholesale prices, are drawn from the Taiwan Statistical Data Book, 1982. Data for foreign demand and foreign prices come from the data bank and models of INFORUM.

#### IV.2 Elasticities (See Table D.4 for figures)

Most of the price elasticities are reasonable. They are either negative or zero. A zero value is superimposed by computation as the lower limit, since positive price elasticity cannot be explained. Unfortunately, for those with negative values, there are no criteria to determine whether they are significantly different from zero. Some sectors with large absolute values of elasticity are:

Sector 6 -- Hogs (-2.2)

Sector 19 -- Tobacco & alcoholic beverages (-2.6)

Sector 23 -- Non-alcoholic beverages (-3.0)

Sector 27 -- Artificial fabrics (-4.4)

Sector 30 -- Miscellaneous fabrics, apparel & accessories (-5.8)

Sector 34 -- Pulp, paper & paper products (-3.0)

Sector 49 -- Steel & iron (-3.1)

This suggests that the exports of these sectors are sensitive to price change. However, they form only a minor fraction of the total exports, and thus elasticity pessimism may still prevail.

By and large, we can say that Taiwan's exports are income elastic, i.e., they rely on the prosperity of foreign countries. One exception is Section 31, Lumber: income elasticity is negative in this sector! The corresponding price elasticity is zero. It seems that nothing can be done to encourage exports from this sector.

## V. Forecasting

We project, on the basis of the estimation results (given in Table D.4 in Appendix D), the exports in real terms for the period between 1983 and 2000. Since no forecast is absolutely correct, we try 12 scenarios for each sector. As we have 61 sectors, this amounts to a report of 732 pages. They will not, therefore, be attached in this paper. (They are obtainable from CHIER upon request.)

These scenarios are

Scenario	Relative price assumption	Total world exports assumption
1	Price unchanged since 1982	Annual growth rate = 2%
2	" " "	= 5%
3	" " "	= 10%
4	Price forecasted with trend calculated from 1966-82 data	" " = 2%
5	" " "	= 5%
6	" " "	= 10%
7	Price forecasted with trend calculated from 1977-82 data	" " = 2%
8	" " "	= 5%
9	" " "	= 10%
10	Same as Scenario 7, but with direct judgement in selected sectors	" " = 2%

11           "       "       "       "       "       = 5%

12           "       "       "       "       "       = 10%

Note that there are no complete time series for Sector 3 (Sugar cane) and Sector 12 (Crude petroleum and natural gas) eligible for use in regression.

The following graphs and figures show the total exports in real terms as estimated from these scenarios. For simplification, only data at five-year intervals are used.

In the first three scenarios, we assumed that relative prices remain at the 1982 level. This may not be too implausible because it represents identical movement of domestic and foreign prices. In an economy as open as Taiwan, the domestic price may quite possibly follow the path of the world price, taking into consideration a time lag, as we have done in this paper.

These three scenarios are the most modest, especially Scenario 1 where the annual growth rate of total exports is as low as 4% between 1995 and 2000. In Scenario 1, total world exports are assumed to grow at 2% per annum, in Scenario 2, 5%, and in Scenario 3, 10%.

In the second set of scenarios (4-6), we use the projected value of relative price based on the 1966-1982 regression on time:

$$(7) \quad \ln P_t = a + b.t$$

And in Scenarios 7-9, price projection is based on the 1977-1982 regression.

Table 1 12 Forecasting Scenarios of Taiwan's Total Exports

	1980	1985	1990	1995	2000
SC1	639.7	923.73 (8%)	1218.10 (6%)	1521.44 (5%)	1846.77 (4%)
SC2	639.7	949.59 (8%)	1312.21 (7%)	1724.03 (6%)	2222.37 (5%)
SC3	639.7	1000.61 (9%)	1565.82 (8%)	2505.49 (10%)	4423.13 (12%)
SC4	639.7	1040.95 (10%)	1765.44 (11%)	2820.53 (10%)	4795.83 (11%)
SC5	639.7	1068.57 (11%)	1901.18 (12%)	3258.86 (11%)	6175.27 (14%)
SC6	639.7	1123.32 (12%)	2262.93 (15%)	4868.17 (17%)	13199.09 (22%)
SC7	639.7	973.84 (9%)	1470.51 (9%)	2275.25 (9%)	3969.37 (12%)
SC8	639.7	1000.11 (9%)	1589.47 (10%)	2661.10 (11%)	5253.24 (15%)
SC9	639.7	1052.1 (10%)	1906.97 (13%)	4089.88 (16%)	11362.53 (24%)
SC10	639.7	973.73 (9%)	1471.06 (9%)	2277.77 (9%)	3974.70 (12%)
SC11	639.7	979.99 (9%)	1590.00 (10%)	2663.73 (11%)	5252.05 (15%)
SC12	639.7	1051.96 (10%)	1907.45 (13%)	4092.91 (16%)	11370.75 (24%)

Note: Figures in parentheses are average annual growth rates

Fig. 1 Scenarios 1-3 of Taiwan's Total Exports

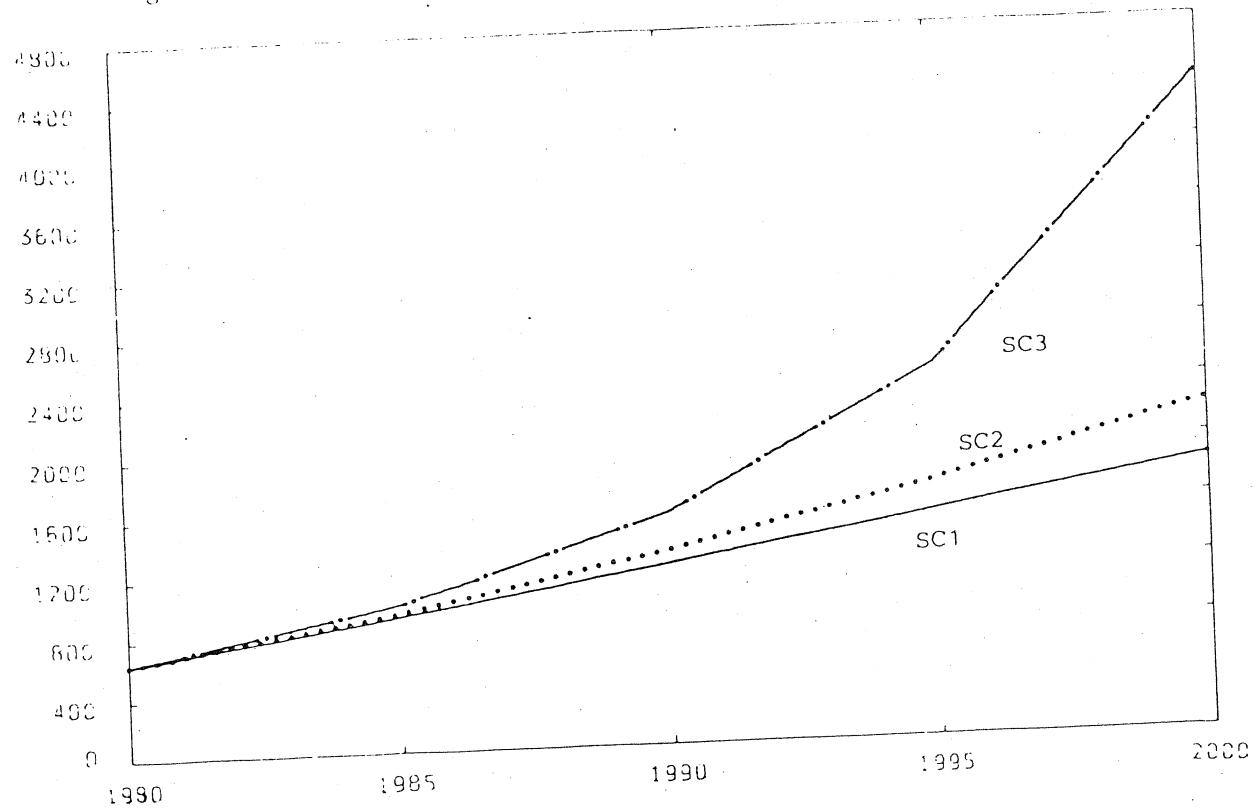

Fig. 2 Scenarios 4-6 of Taiwan's Total Exports

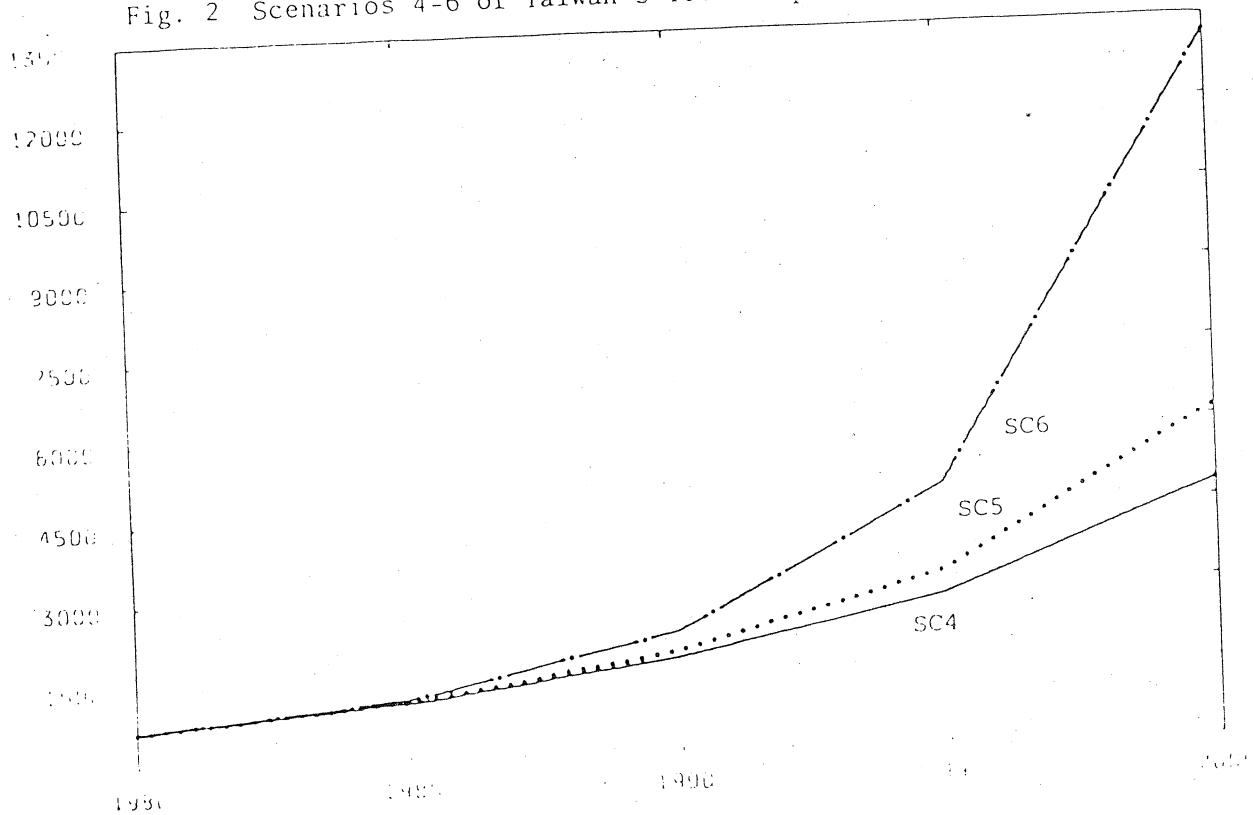

Fig. 3 Scenarios 7-9 of Taiwan's Total Exports

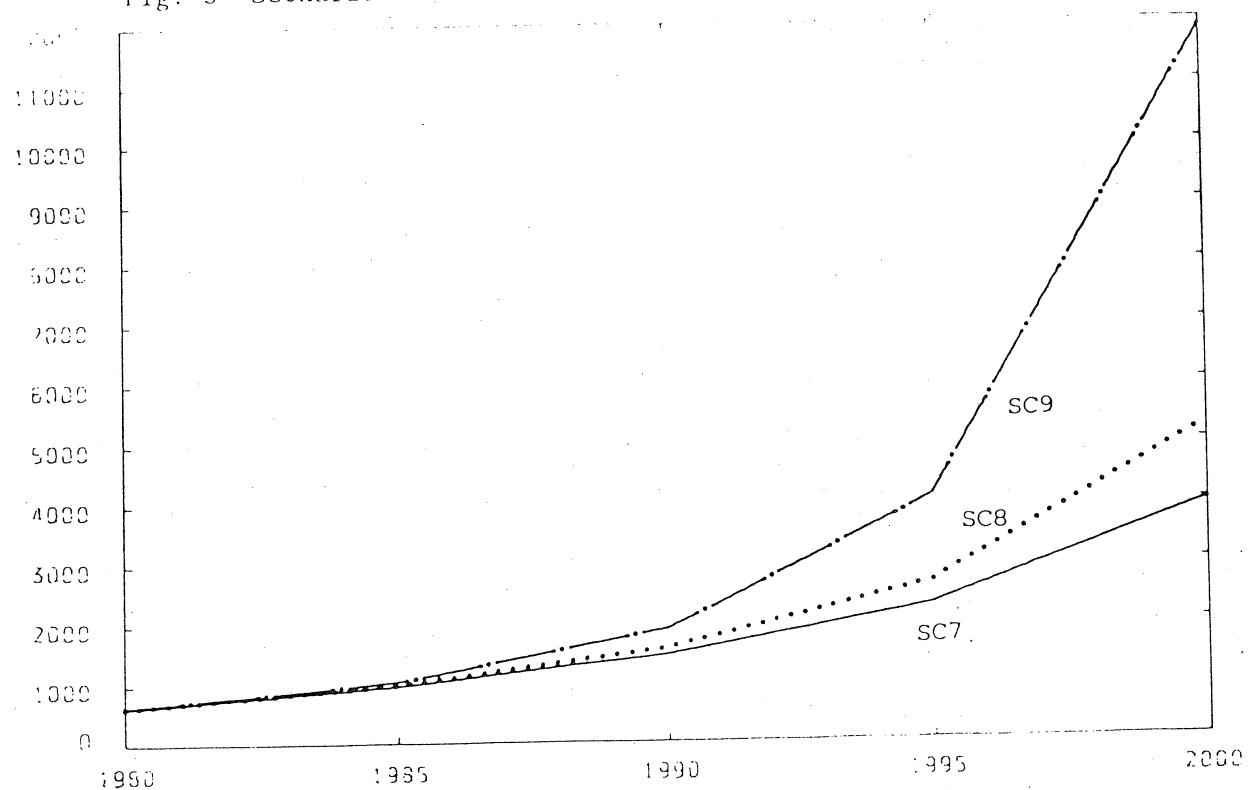

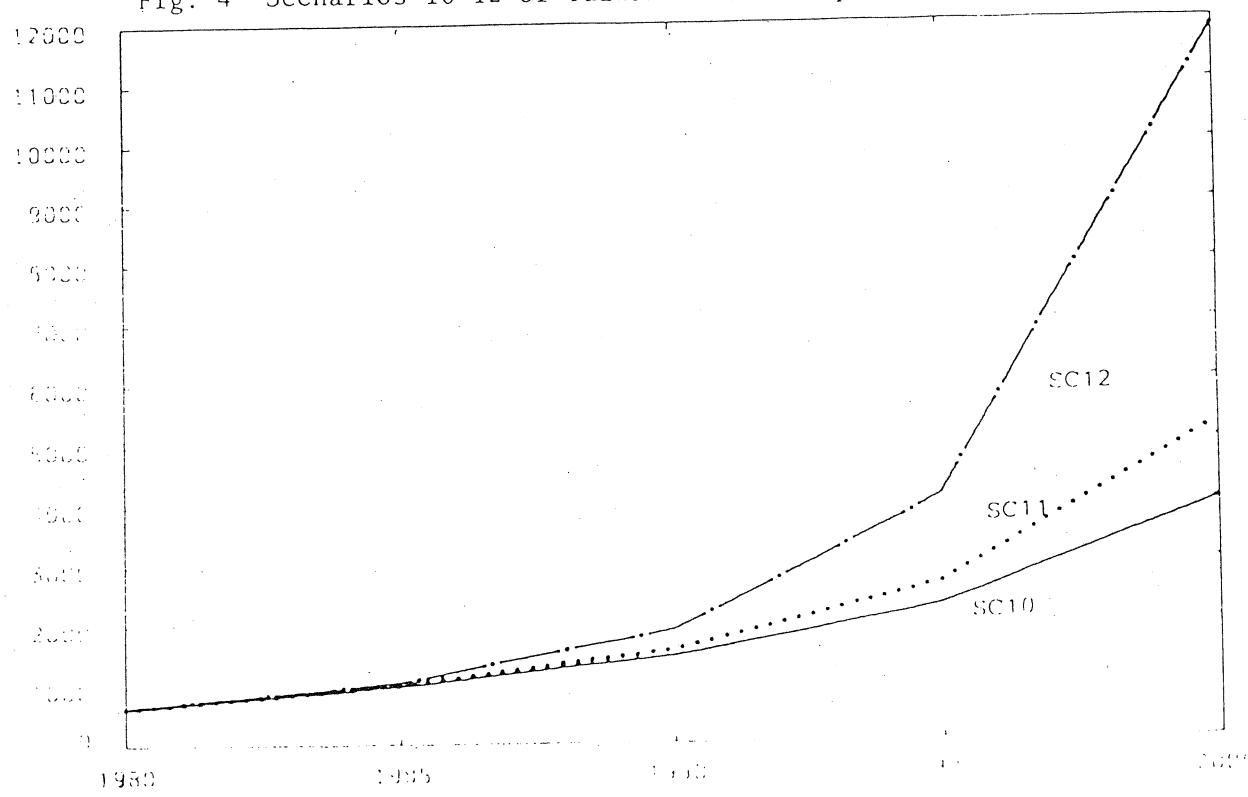

Fig. 4 Scenarios 10-12 of Taiwan's Total Exports

While we observed from Section IV.2 that price effects are negative, unchanged relative prices lead to smaller growth of total exports from Taiwan than do prices with trend. This implies that some important sectors have had negative trends of relative prices in the past, and such negative trends were more serious in the period 1977-1982 than in 1966-1982. This phenomenon is especially obvious in the following sectors: Sectors 23-29 and Section 51-53.

## VI. Concluding Remarks

Though there is not much to be concluded from a technical paper like this, some words have to be said at least for future reference.

This work has been done for two purposes:

1. It provides future forecasts for possible policy consideration;
2. It is the beginning of long-term project :- the building of a complete INFORUM-type model for Taiwan.

The first purpose is perhaps well fulfilled. We have made estimations and forecasts on disaggregated data, which has been done with linkage to models of most of Taiwan's major trading partners. We are, therefore, confident that the results are reasonable.

Although this paper has also fulfilled the second purpose, there is still much to do in the future. It is hoped that a complete and better model of the INFORUM-type can be finished in due course.

## Appendix

## C.2 Conversion Table, SITC to I-O (76) Sectors

1	4	60.250	70.250	80.250	180.250
2	1	251.000			
3	1	91.000			
4	4	10.250	20.250	40.250	50.250
5	2	150.500	210.500		
6	1	31.000			
7	2	170.500	250.500		
8	1	161.000			
9	2	240.500	250.500		
10	0	240.500			
11	2	220.500	420.500		
12	2	190.500	230.500		
13	1	191.000			
14	1	361.000			
15	1	371.000			
16	1	311.000			
17	1	341.000			
18	1	301.000			
19	1	301.000			
20	1	301.000			
21	1	381.000			
22	2	130.500	140.500		
23	1	111.000			
24	1	111.000			
25	1	51.000			
26	1	101.000			
27	1	121.000			
28	1	411.000			
29	1	121.000			
30	1	621.000			
31	3	200.330	430.330	440.340	
32	1	441.000			
33	2	340.500	440.500		
34	1	441.000			
35	1	381.000			
36	1	441.000			
37	1	401.000			
38	1	371.000			
39	1	321.000			
40	1	351.000			
41	1	341.000			
42	1	341.000			
43	1	341.000			
44	1	341.000			
45	1	261.000			
46	1	281.000			
47	1	241.000			

Note: Column 1 shows the number of SITC groups as given in Table C.1; Column 2 shows in how many sectors this SITC group will be broken down. Each of the other columns indicates the number of the I-O sector and the share of the SITC group attached. For example, 60.250 means the I-O sector number 60 with a weigh of 0.25 belongs to this SITC group.
