Is Smallholder Farming Economically Viable? Evidences from Village Dynamics Studies in Karnataka, Peninsular India[1]

I

INTRODUCTION

Indian agriculture is numerically dominated by small and marginal farmers who constitute around 83 per cent of the total holdings and Karnataka state is no exception. Over 56 per cent of the state population depends on agriculture for their livelihood. A majority of these are small and marginal farmers with land less than 2 ha. Thus, small holder agriculture is expected to continue in the foreseeable future with rise in population pressure on land and demand for land for competing alternative uses. In this regard, the emerging challenges for small holder farmers include inadequate access to markets, infrastructure, and technology; high marketing and transport costs; and limited resources (Fan *et al*., 2003). Farmers to continue in the agriculture with declining resource base particularly land would require a steady flow of income from farming alone or farming along with other income generating activities. Of late, due to vagaries of climate change, rising labour costs and associate sharp fall in agricultural incomes, the viability of smallholder farms is threatened and is at stake, hence many small farmers are drifting out of agriculture to non-farm activities. The key challenge is how to improve the income of small farms with a focus on enhancing productivity and profitability which is sustainable on long-run so that small farmers can stay on their farming business. In this regard, this paper examines the economic viability of smallholders farming considering the average incomes generated from different sources in typical semi-arid villages of Karnataka.

Focus of the Study

The main focus of the study is to assess the economic viability of smallholder farming in typical semi-arid villages of Karnataka considering different sources of farm and non-farm income generated.

*Former Principal Scientist, Principal Scientist, Lead Scientific Officer, Research Programme Director, Scientific Officer, respectively (Markets, Institutions and Policies), ICRISAT, Patancheru.

[1]This paper forms part of the VDSA project (Village Dynamics Studies in South Asia) supported by the Bill & Melinda Gates Foundation (BMGF), currently in progress at ICRISAT, Patancheru.

II

METHODOLOGY

The ICRISAT Village Dynamics in South Asia, (VDSA) collects the panel data from the selected village households by employing resident field investigators who stay in the selected villages and collects the household data by personal interview. A sample of 40 respondent households was selected to represent four categories of household's landless labour, small farmers, medium farmers and large farmers. The farm household categories were defined on the basis of the pattern of landholding in each village. Ten households were randomly selected from each stratum inferring equal sampling fractions in each size group and for analysis purposes the cultivator sample is a uniform random sample. However, the labour category has not been included in the analysis as they do not have substantial crop based activities. The farmers have been further categorised into viable and non-viable based on average surplus income over costs generated for the past 3 years. Empirical estimation is done through analysis of household level panel data collected from 160 households located in four villages of Tumkur and Bijapur districts of Karnataka for four years (2009-2012) by ICRISAT under the Village Dynamics Studies in south Asia (VDSA) project.

Characterisation of Sample Districts and Villages

In Karnataka, Bijapur and Tumkur districts have been chosen for the VDSA project since 2009. The villages selected include Markabinahalli (Basavana Bagewadi, Taluk) and Kapanimbargi (Indi, Taluk) in Bijapur, Tharati (Korategere, Taluk) and Belladamadugu (Madhugiri, Taluk) in Tumkur district. Bijapur district is located in Northern maidan (plateau) region of Karnataka with semi-arid climate and a large proportion of this district is under marginal production environment with 37 rainy days in a year facing severe droughts. The district has high concentration of horticultural crops under groundwater irrigation. Both rainfed and groundwater based agriculture is heavily dependent on monsoons. Similar to Bijapur, Tumkur district lies in southern Karnataka, a typical semiarid region facing frequent droughts with hardly 33 rainy days in a year.

Contrasts between Bijapur and Tumkur Villages

The size of holdings are higher ranging between 4 – 8 ha in north Karnataka (Bijapur), on the contrary, the size of holdings are extremely small ranging between 0.25 – 2 ha in the southern Karnataka (Tumkur). In Bijapur, farmers are under investing in dry land agriculture due to risk and uncertainty in rainfed agriculture, while groundwater irrigated farmers are over investing on well irrigation and horticultural crops production and processing. On the contrary, in Tumkur villages due to small holdings, there is intensification of agriculture with the use of external

inputs. With access to bore-well irrigation, the cropping patter has changed from finger millet dominant mixed cropping to diversify commercial farming.

Key Features of VDSA Villages

The salient features of VDSA villages are provided in the table (Table 1)**.** The proportion of cultivated area out of the total geographical area is relatively higher in Bijapur district (94 – 95 per cent) as against Tumkur (44-73 per cent). With respect to size of holdings, the disparities are more discernible in Bijapur villages compare to Tumkur villages, as the proportion of landless households is more in Bijapur villages. Around 39 per cent of the area is irrigated in one of the villages in Bijapur and another village completely rainfed. While, the area under irrigation is slightly more Tharati village compare to Belladamadugu, because of extremely small size of holdings in Tharati of Tumkur district. The households in Bijapur have bigger family size and more literacy compare to Tumkur villages. Seasonal migration is observed in households belonging to Kapanimbargi village, as this village has highest number of landless households. Bijapur villages have black cotton and red soils, while Tumkur villages have red sandy soils. The cropping pattern shows a combination of food and commercial crops in all the 4 villages.

TABLE 1. SALIENT FEATURES OF VDSA VILLAGES IN KARNATAKA

	Bijapur		Tumkur	
Particulars/villages	Markabinahalli	Kapanimbargi	Belladamadugu	Tharati
(1)	(2)	(3)	(4)	(5)
# of HH's	392	320	276	401

Per cent of Irrigated area	0	39	27	29
Per cent of landless households	28	33	10	28
Family size	6.47	6.23	4.43	4.24
Literacy	64	60	49	24
Size of holding (Ha)	3.29	3.6	1.45	1.03
Seasonal migration (per cent of HH)	-	12	-	-
	Bio physical features			
Annual Rainfall (mm)	412.4	376.5	472.2	735.4
Soil type	Deep to medium black	Red	Red sandy	Red sandy loam
Crops grown during Kharif	Pigeon pea, Cotton, Onion	Pigeon pea, Maize, Groundnut, Pearl millet, Onion	Groundnut, Paddy, finger millet, Pigeon pea, Horse gram	Finger millet Paddy, Cut flowers, Horse gram, Ground nut
Crops grown during Rabi	Chickpea, Sorghum, Wheat, Safflower	Sorghum, Wheat, Chickpea, Maize, Onion	Paddy, Groundnut, Flowers and Vegetables	Flowers, Vegetables, Sorghum fodder
Perennial crops	–	Grapes, Ber, Pomegranate	Arecanut	Arecanut, coconuts, Betelvine

General Characteristics of Sample Farmers in VDSA Villages of Karnataka:

The demographic features of the sample farmers in VDSA villages of Karnataka indicate that the average family size comprised of 5-6 members with a literacy level of 4-5 years (Table 2). In terms of social profile, barring Belladamadugu village, majority of the farmers (>80 per cent) belong to OBC. In terms of youth involvement in agriculture, only 5-8 per cent of the youth in Tumkur villages are engaged in agriculture as against 15 per cent in Bijapur villages. This indicates youth disinterest in agriculture. Age cohort indicates that around 1/3rd of the farmers are above 60 years age and more than 50 per cent of the farmers are in middle age in all the villages. The striking feature that differentiates between Bijapur and Tumkur villages is that of size of holdings, which are extremely small in Tumkur villages as compared to Bijapur.

TABLE 2. GENERAL CHARACTERISTICS OF SAMPLE FARMERS IN VDSA VILLAGES OF KARNATAKA

Particulars	Markabbinahalli	Kapanimbargi	Belladamadugu	Tharati
(1)	(2)	(3)	(4)	(5)
Family size	6	6	5	5

2.Middle aged (35-55 years) per cent	47 (43.9)	38 (43.9)	58 (44.1)	59 (44.2)
3. Aged farmers (> 55 years) per cent	38 (65.1)	46 (61.5)	34 (65.8)	36 (65.4)

Note: Figures in parenthesis indicates average age in years.

Cropping Pattern for Different Size of Holdings in VDSA Villages of Karnataka:

Cropping pattern across different size groups in VDSA villages of Karnataka is given in Table 3. The cropping pattern indicates a combination of food and commercial crops in all the 4 villages. In Bijapur villages, major share of the area was under pigeon pea and cotton in Kharif and sorghum and chick pea in post-rainy season. In Belladamadugu village, groundnut is the major crop in both the seasons, while in Tharati village the major crops grown are finger millet in *kharif* and flowers in all the 3 seasons. Grapes in Kapanimbargi village of Bijapur district and Chrysanthemum, areacanut and betelvine crops in Tharati village in Tumkur district are major horticultural crops. The cropping pattern shows that most of the small

farmers in Bijapur allocated their meager area towards food crops, while in Tumkur villages small farmers allocated their area for both for food and commercial crops. On the contrary, majority of the large and medium farmers allocated more area towards commercial crops. Thus, most of the small farmers are food security oriented, while most of the large farmers are economic security oriented.

Income from Crop, Livestock and Off Farm in VDSA Villages of Karnataka during 2009-11:

The income realised from crop, dairy and off farm is indicated in Tables 5-6 for all the 4 VDSA villages and it is represented in Figures 1 and 2. The economic

analysis of different sources of income across different size groups reveals a wide gap in all the 4 villages. In Markabinahalli, on an average, the total net return derived from crops by a large farmer is 7.5 times higher than a small holder farmer. However on hectare basis, the net returns realised is only 1.4 times higher. Similarly, in Kapanimbargi village, the total net return realised from crops by large farmer is 65 times higher than smallholder and on hectare basis, it is 14 times higher (Table 7). This disparity is mainly because of two factors. In Markabinahalli, entire cultivated area is under rainfed and farmers do not have any access to irrigation and hence the choice of cropping pattern is a combination of food and commercial crops, while in Kapanimbargi, around 40 per cent of the area is under irrigation and hence majority of the farmers grow high value horticultural crops like grapes under groundwater irrigation. The return to cost ratio for all the crops cultivated by farmers indicates that the ratio is quite significant for large farmers compared to small farmers in Kapanimbargi but not much variation in Markabinahalli, while in Tharati, the cost benefit ratio is very appreciable for most of the crops. This is due to the effect of horticultural crops grown in these two villages, which are more lucrative.

TABLE 5. INCOME FROM CROP, LIVESTOCK AND OFF FARM IN BIJAPUR DISTRICT DURING 2009-11

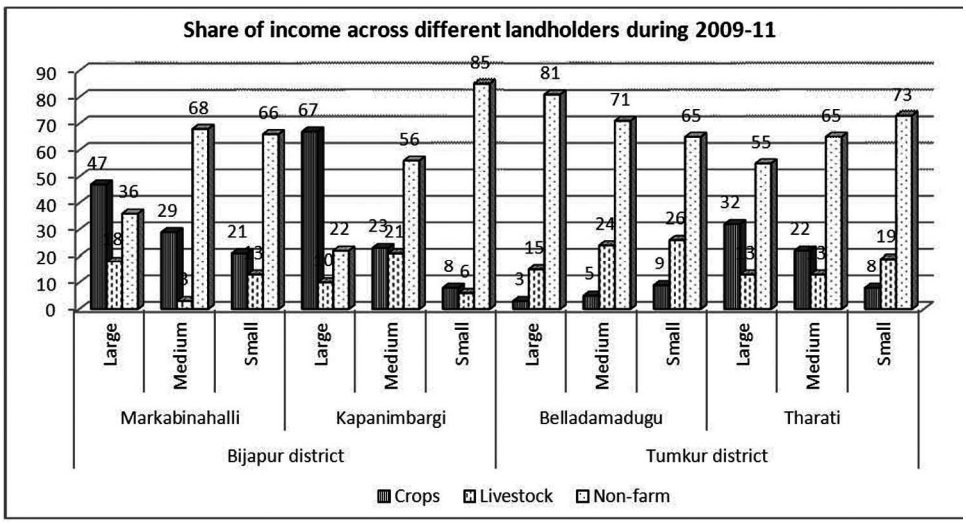

Figure 2. Share of Income across Different Landholders during 2009-11

TABLE 7. COMPARISON OF PER HECTARE RETURNS FOR DIFFERENT FARM SIZE GROUPS

Village (1)	Ratio of Net return of large to small farmer (farm) (2)	Ratio of Net return of large to small farmer (per ha) (3)
Markabinahalli	7.5	1.4
Kapanimbargi	65	14
Belladamadugu	0.9	0.34
Tharati	6.2	2.5

The net income derived from crops per hectare by small farmers is almost 2.8 times higher than medium and large farmers in Belladamadugu, since the proportion of irrigated area of small farmers is much higher (40 per cent) than large farmer (20 per cent). While in Tharati, virtually all the farmers comes under small holders and their income realised is quite high per hectare, as they grow commercial flower crops under irrigation. Studies also indicated that the small farmers increased their income through diversification even under shrinking farm sizes (Hazell and Rahman, 2013). As evident, the income derived from crops/ha by the small holders is inadequate to meet their living. Thus, small farmers relay on diversified sources of income especially nonfarm in Bijapur villages. Hence seasonal migration is evident in Kapanimbargi village. On the contrary, the income derived from crops by small holders in Tumkur villages is quite significant. This is mainly because of intensive cultivation as well as the nature of crops grown.

In terms of total income from all the sources, it is substantially higher in Kapanimbargi when compared to Markabinahalli in Bijapur district for all the groups.

But in case of Tumkur district, total income was higher in Tharati than in Belladamadugu.

It is striking to note that the proportion of non-farm income realised by small farmers is much higher (66 to 85 per cent) in Bijapur villages, while the proportion of non-farm income is quite remarkable across all the groups in Tumkur villages (65 to 73 per cent). The percentage of households depending on non-agricultural activities is relatively more in Tumkur villages compared to Bijapur villages. This is due to; 1) in Tharati, land holdings are extremely small (0.2 to 1.5 ha) hence, many households depend on other non-agricultural activities 2) in Belladamadugu, groundnut based farming system is dominant, but its performance is highly uncertain due to vagaries of nature. Hence majority of the households are involved in non-agricultural activities like brick making, leaf plate making, and petty business. In Tumkur villages, the livestock and milk production are the major sources of income to the households especially in Belladamadugu village. Thus, small farmers are likely to remain unviable if they do not get access to off-farm income (Singh *et al*., 2009) In general, there has been sharp fall in the proportion of income derived from agriculture and rise in the non-farm income derived across all size groups (specifically in medium and small holders), particularly this is more evident with small holders under rainfed situation in Kapanimbargi and Belladamadugu. Considering annual expenditure for both food and non-food per household, net annual income realised from crops indicated negative surplus from medium and small farmers in Bijapur district and all the farmers realised negative surplus in Tumkur district. This result mystifies how the small farmers with less annual income from crops manage their livelihood. Thus it is evident that the agricultural income realised from small holder farmers is inadequate to meet their living and hence diversified sources of income especially non-farm income.

Income from Different Enterprises over the Years for Small Farmers

Income realised from different enterprises for small farmers in both dry and irrigated situations in VDSA villages of Karnataka is indicated in Table 8-10. The disaggregation analysis of dry and dry+irrigated is not analysed for village Markabinahalli from Bijapur district, since it is completely rainfed area. The results indicate that the net income derived from crops is relatively higher in irrigated situations than dry conditions. On an average, net returns realised from crops is negative being Rs. -1135 in dry land as against Rs. 10817 per farm in irrigated area in Kapanimbargi. In Belladamadugu, net returns realised from crops in rainfed situation is very low to the tune of Rs. 128 and Rs. 15316 per farm under irrigated area. In Tharati village, a net return realised under rainfed conditions is Rs. 5558 as against Rs. 8683 under irrigated conditions. This indicates that under dry land situations the farmers realised paltry returns which are less than the minimum wages (Rs.141 per day) prescribed for a decent living. The share of income from non-farm is more than half of the total income in all the villages in dry and irrigated conditions, which is

Total income	63200	95372	93839	84137

Note: Figures in parenthesis indicate per cent of income over total income.

Crops cultivated: wheat, pearl millet, sorghum, maize, ground nut, pigeon pea, chickpea, green gram, cotton etc.

supported by the study by Hazell, 2003. Barring Tharati village, on an average, the total income is higher for farmers with irrigation facility compared to the farmers without irrigation in other two villages. The share of non-farm income of irrigated farmers is slightly less compared to dry farmers. In Belladamadugu village, it is observed that total income is relatively higher for irrigated farmers than dry farmers.

Number of Viable and Non-Viable Farmers with Crop and Livestock Income

The economic viability of farm defined by the surplus income derived from crop enterprises after deducting all costs is provided in the Table 11 and represented in the Figures 3-4. Considering the surplus income over costs from crops alone, all the large and small farmers and 50 per cent of the medium farmers are viable in Markabinahalli, while 50 per cent of the small, 40 per cent of the medium and 75 per cent of the large farmers are viable in Kapanimbargi. Similarly, in Belladamadugu, and Tharati most of the small farmers are viable. It is intriguing to note that even by considering both crop and livestock incomes, around 22-29 per cent of the medium and large farmers in Belladamadugu are not viable, while most of the small farmers are viable with livestock income across all the villages.

TABLE 11. PERCENTAGE OF VIABLE AND NON-VIABLE FARMERS WITH INCOME

Class of holdings	Bijapur district				Tumkur district			
	Markabbinahalli		Kapanimbargi		Belladamadugu		Tharati	
	Viable	Non-viable	Viable	Non-viable	Viable	Non-viable	Viable	Non-viable
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
				Crop income				
Large	89658	-	368152	-9474	13000	-10994	45508	-
	(100)		(75)	(25)	(29)	(71)	(100)	
Medium	25341	-4400	40160	-16109	8039	-5092	22285	-5107
	(50)	(50)	(43)	(57)	(33)	(67)	(71)	(29)
Small	11860	-	7404	-1810	13527	-5184	13037	-5538
	(100)		(50)	(50)	(63)	(37)	(87)	(13)
				Crop + Livestock income				
Large	123956	-	413361	-	20379	-8249	63362	-
	(100)		(100)		(71)	(29)	(100)	
Medium	26285	-4192	58686	-10922	18962	-3770	27507	-
	(50)	(50)	(86)	(14)	(78)	(22)	(100)	
Small	19507	-	12261	-2610	31776	-	24065	-
	(100)		(88)	(12)	(100)		(100)	

Note: Figures in parentheses are percentage of farmers.

Specifically for small holder farmers, considering economic surplus generated on the farm all farmers are viable in Markabinahalli, while 50 per cent of small farmers in Kapanimbargi, 63 per cent of small farmers in Belladamadugu and 71 per cent of small farmers in Tharati are viable with crop income per se. When considered both crop and livestock income, barring Kapanimbargi (88 per cent) village 100 per cent of small holder farmers are viable in Markabinahalli, Belladamadugu and Tharati villages.

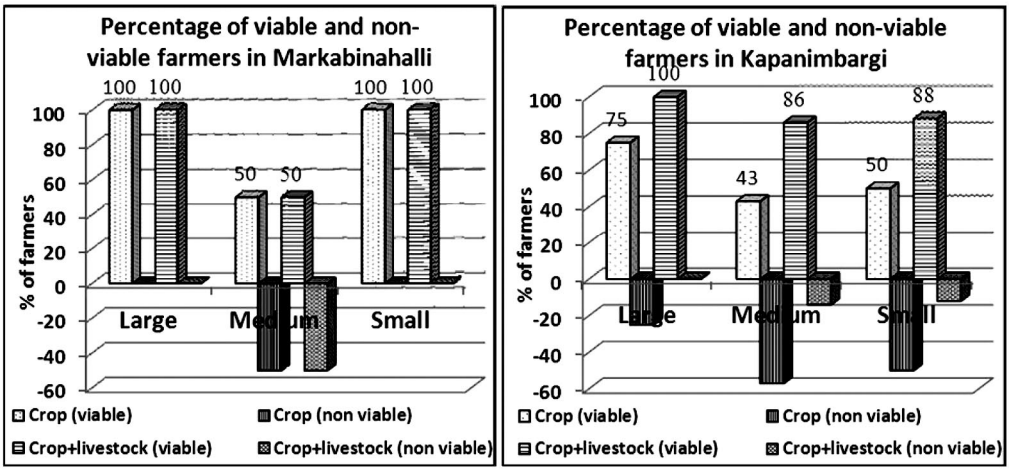

Figure 3. Percentage of Viable and Non-viable Farmers during 2009-11 in Bijapur District

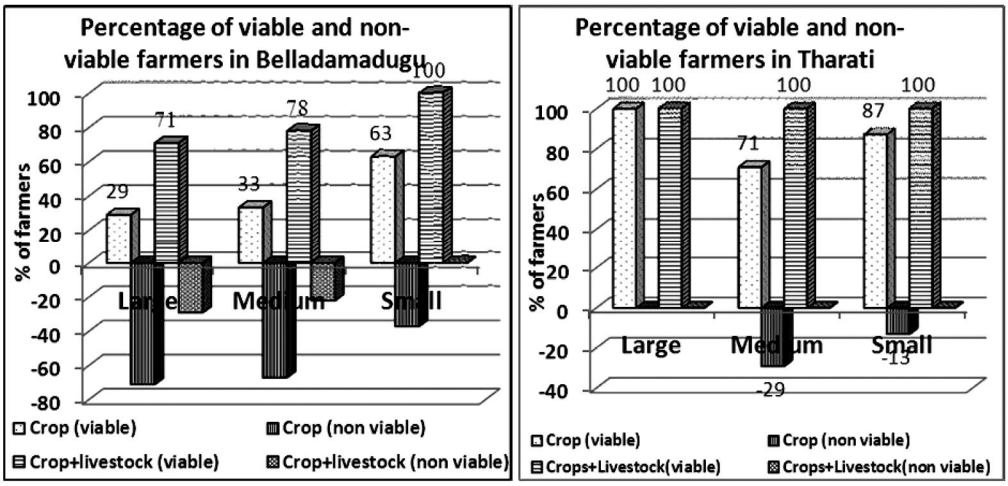

Figure 4. Percentage of Viable and Non-viable Farmers during 2009-11 in Tumkur District

Viability of Small Farmers with Crop Income under Dry and Dry + Irrigated Conditions

Considering average economic surplus generated on the farm for the past 3 years by crops alone in rainfed situation, most of the smallholdings are not economically viable in Kapanimbargi (Rs. -1135) village of Bijapur district, while 50 per cent of

them are not viable in Belladamadugu (Rs. -4900) and 17 per cent them are non-viable in Tharati (Rs. -1504) villages of Tumkur district. However, all the smallholdings are viable in Markabinahalli (Rs. 11860) of Bijapur district, as the rainfed agriculture in this village is characterised by low input use intensity with a combination of food and commercial crops like rabi sorghum, cotton, chickpea, safflower and onion. However, even with access to irrigation, 25 per cent of the small farmers in Kapanimbargi (Rs. -6819), 33 per cent in Belladamadugu (Rs. -3777) are non-viable. However all the smallholders are economically viable in Tharati (Rs. 9647) with access to irrigation, as they are specialised in growing flower crops, areca and betel-nut with emerging water markets (Table 12). Though small holder farmers are viable, but the size of net margin (surplus income) generated per hectare is very meager and virtually not adequate to meet their livelihood, hence, they heavily rely on non-farm income. Unless the crop based productivity and profitability increase substantially, the viability of small holders is threatened.

TABLE 12. VIABILITY OF SMALL FARMERS WITH CROP INCOME UNDER DRY AND DRY+IRRIGATED CONDITIONS

		Dry		Dry + Irrigated	
Region	Particulars	Viable	Non-viable	Viable	Non-viable
(1)	(2)	(3)	(4)	(6)	(7)
Kapanimbargi	Percentage	0	100	75	25
	Income		-1135	17062	-6819
Belladamadugu	Percentage	50	50	67	33
	Income	5028	-4901	19660	-3777
Tharati	Percentage	83	17	100	0
	Income	6584	-1504	9647	

III

CONCLUSIONS

Cropping pattern across different size groups in VDSA villages of Karnataka indicates a combination of food and commercial crops. Most of the small farmers in Bijapur allocated their meager cultivated area towards food crops, while in Tumkur villages small farmers allocated their area for both for food and commercial crops. There has been sharp fall in the proportion of income derived from agriculture and rise in the non-farm income derived across all size groups. In Kapanimbargi village, large and medium farmers derived a significant proportion of income from horticultural enterprises like grapes, while small farmers did not derive any income from horticulture crops, as they are highly capital intensive and need irrigation. Considering average economic surplus generated on the farm for the past 3 years by crops alone in rainfed situation, most of the smallholdings are not economically viable in Kapanimbargi, while 50 per cent of them are not viable in Belladamadugu and 17 per cent them are non-viable in villages of Tumkur district. However, all the smallholdings are viable in Markabinahalli of Bijapur district. However, even with

access to irrigation, 25 per cent of the small farmers in Kapanimbargi and 33 per cent in Belladamadugu are non-viable. However all the smallholders are economically viable in Tharati with access to irrigation, as they are specialised in growing flower crops with emerging water markets. Though some of the small farmers are economically viable in terms of surplus income generated from crops, yet the size of the net margin realised per hectare is very low. Considering annual expenditure for both food and non-food per household, net annual income realised from crops indicated negative surplus from medium and small farmers in Bijapur district and all the farmers realised negative surplus in Tumkur district. Thus the agricultural income realised from small holder farmers is inadequate to meet their living and hence diversified sources of income especially nonfarm income. It is puzzling to note that most of the small holdings are not economically viable under rainfed conditions that constitute around 80 per cent of the total agricultural holdings and mange to live with such paltry income. Overwhelmingly, small farmers live at the margins, and survive through a large range of nonfarm income. Small farmers are likely to remain unviable if they do not get access to off-farm income. In order to enhance the viability of small farms, technology driven options to accelerate productivity, profitability and pro-small farmer value chains are vital for policy intervention. Further, smallholder farmers need appropriate risk mitigation and coping strategies along with social safety net measures. In addition, non-farm diversification needs strong policy support towards infrastructure, transport, storage, credit and market.
