# BRAZILIAN TRADE DURING THE LAST CENTURY 

Eliana A. Cardoso<br>Boston University

The paper studies the Brazilian trade balance between 1907 and 1980. The first section analyses exchange rate behavior and the second examines the empirical evidence concerning the elasticities approach. The third discusses the trade balance using the savings investment approach and analyses the foreign interest rate effects on our trade account. Data construction is carefully described in the Appendix, where protection indices and different exchange rate regimes are reported together with the data used in the paper.

1. Real and nominal exchange rates

During the last quarter of the past century, until 1906, the Brazilian exchange rate regime was one of floating exchange rates. Behavior of exchange rates during that period is discussed in Cardoso (1982). In 1906, the creation of the Caixa de Conversä́o institutionalizes government intervention in the exchange market. Between $1906 / 17$, the exchange rate oscillates around the rate fixed by the Caixa de Conversäo in the free market. Although restrictions were imposed in 1917 on capital flows, and the Caixa de Estabilizaçâo was created in 1926 to stabilize the exchange rate, the period between 1907/1930 can be seen as one characterized by the existence of a unified exchange rate and a free market, where the government intervened through different devices (monetary and coffee policies) to keep the exchange rate at a chosen level.

Control over exchange transactions was introduced in 1931 and amended several times. With the $1929 / 30$ crisis, exchange reserves disappeared, the Caixa de Estabilizaçảo was closed and the monopoly of exchange transactions by the Banco do Brasil was established. In 1931/32, a black market for exchange appears and from then on, the existence of at least more than one rate is observed.

The informal system of more than one exchange rate that appeared after 1931 is officialized in 1939 with the creation of a system with three exchange rates: free, official and special. (See Appendix for details.) By the end of 1953, a free market was introduced as well as an auction system for imports. Under this system (1953/60), exchange certificates were auctioned for five different categories of imports, established on the basis of their essentiality. This system also provided for bonuses to be paid to different categories of exports on the basis of exchange surrendered.

In March 1961, the auctioning system was abolished and transactions at par value were discontinued, and the reform of the exchange system led to three foreign exchange markets: the market of the monetary authorities, the market of the authorized banks and the manual market. However the policies pursued by the authorities slowly unified the three markets by 1964. A black market continues to exist, but its importance appears to be minor. In 1968, a system of crawling peg was introduced, according to which the exchange rate is devalued at irregular intervals, in small amounts, following the difference between inflation at home and abroad.

Table 2.A. in the Appendix reports the dollar/cruzeiro exchange rate in the free market as well as the relevant exchange rates for imports and exports, and explains how they were calculated. Table 6.A. in the Appendix
reports five different measures for the real exchange rate: $F X$ is the real effective exchange rate in the free market using exports weights, FM is the real effective exchange in the free market using imports weights and D is the real dollar/cruzeiro rate in the free market. (See Appendix for details.) The correlation between any two of the three exchange rates is above .9; in what follows we leave aside effective exchange rates and use dollar exchange rates. $D X$ is the real dollar exchange rate for exporters inclusive of subsidies and $D M$ is the real exchange rate for importers inclusive of tariffs and other protection mechanism, like import deposits. Diagram 1 depicts the behavior of the real dollar exchange rate and Table $I$ reports the behavior of the five measures of the real exchange rate, suggesting that deviations from Purchasing Power Parity do have persistence. The hard core view of Purchasing Power Parity (PPP) asserts the law of one price: arbitrage by market participants will establish uniformity of price in closely related markets. A more fexible view would argue that price adjustment depends on substitution effects. As we become more competitive, demand would shift toward our goods putting upward pressure on costs and prices. If prices only move slowly, deviations from PPP are not only possible but may persist over time. The empirical content of PPP. can be tested by regressing the $\log$ of real exchange rate on its own lagged value and a constant. Results reported on Table 1 show that deviations from PPP have persistence. Less than one fourth of the real exchange rate depends on its long run value and at least three fourths depends on its recent history.
2. The elasticities approach

Figure 2 shows the behavior of the log of the ratio between Brazilian exports and imports.

Figure 2

Brazilian Trade Balance: $\log (X / M)$

The trade balance, defined as the difference between exports and imports is assumed to depend on relative prices and on income at home and abroad. In this section we report the results obtained from the estimation of export and import equations, as well as reduced forms for the trade account. Table II shows the results obtained from the estimation of an export equation. The dependent variables are all real exports except coffee. Equation (1) estimates the supply of exports net of coffee, under the assumption that for all exports, except coffee, Brazil can export all it wants at the international price. Construction of a real exchange rate for exporters inclusive of subsidies is explained in the Appendix. Results show a supply price elasticity of exports equal to .17 in the short run and approximately 2 in the long run.

Equation (2), reported in Table II shows real imports net of oil as a function of their real price inclusive of tariffs. The real exchange rate for imports and its construction are reported and explained in the Appendix. The price elasticity of imports net of oil is equal to -.21 in the short run and approximately -1 in the long run. Income effects are separated into cyclical effects, captured by the parameter of income growth ( $\mathrm{b}_{2}$ ) and trend effects, captured by $b_{4}$. Both appear with positive signs.

Reduced forms equations for the trade balance net of coffee and oil (equations (3) and (4)) as well as equations for the total trade balance (equations (5) and (6)) are reported in Table III.

Table II

|  | $(3.39)$ | $(-2.58)$ | $(3.69)$ | $(14.69)$ | $(2.62)$ |  |  |  |

NOTE: Equations were estimated by OLS; t-statics are reported in parentheses.

The equation for the trade balance net of coffee and oil behaves very well. Price and income effects have the predicted signs. As expected, an increase in domestic growth above foreign growth deteriorates the trade balance. This effect is captured by $c_{4}$. On the other hand, an increase in the real exchange rate improves the trade balance. The elasticity of the trade balance in relation to the real exchange rate is .5 in the short run and 1.8 in the long run. Subsidies also appear with the expected positive sign. The coefficient for tariffs appears more troublesome, being negative and imprecisely estimated. The possibility of an adverse effect of an increase in tariffs on the trade balance would require not only a very large share of imported intermediates in exports and a very large elasticity of exports in relation to their price, but also a very small response of imports in relation to their real price. The elasticities previously obtained in the equations for exports and imports do not support such hypotheses and the fact that the coefficient for tariffs in the trade balance equation is imprecisely estimated leaves this question unsettled.

Equations for the trade balance inclusive of coffee and oil do not behave well. The coefficient for the real exchange rate is very small and very imprecisely estimated. Both the coefficients for subsidies and tariffs appear with the wrong sign and are imprecisely estimated. One would say that the elasticities approach is an adequate estimation procedure for structural equations of export and imports but leads one into problems in the estimation of reduced forms of the trade balance, maybe due to aggregation problems, maybe because important determinants of the trade balance are omitted.

Table IV

Brazilian Trade Balance: The Elasticities Approach 1907-1980
$\log (X / M)=c_{0}+c_{1} \log \left(\frac{E P}{P}\right)^{*}+c_{2} \log S+c_{3} \log T a+c_{4}\left(\hat{Y}-\hat{Y}^{*}\right)+c_{5} \log (X / M)-1+c_{6} t$

|  | $c_{0}$ | ${ }^{C} 1$ | $c_{2}$ | $\mathrm{C}_{3}$ | $c_{4}$ | $c_{5}$ | $c_{6}$ | $\mathrm{R}^{2}$ | SER | D.W. |

| (4) | -2.19 | . 48 | . 22 | -. 25 | -. 66 | . 70 | . 001 | . 72 | . 20 | 2.06 |
|  | $(-2.10)$ | (4.31) | (1.63) | $(-1.48)$ | $(-1.82)$ | (9.35) | (1.11) |  |  |  |
| (5) | . 09 | . 11 | -. 14 | . 02 | -. 68 | . 59 |  | . 49 | . 19 | 2.24 |
|  | (.09) | (1-07) | $(-1.23)$ | (.16) | (-2.07) | (6.34) |  |  |  |  |
| (6) | -. 06 | . 17 | -. 05 | -. 04 | -. 5 | . 37 | -. 005 | . 57 | . 17 | 2.07 |
|  | (-.07) | (1.78) | $(-.5)$ | (-.31) | $(-1.72)$ | (3.46) | (-3.5) |  |  |  |

NOTE: Equations (3) and (4) correspond to the trade balance net of coffee and oil. Equations (5) and (6) use the total trade balance: Exports (FOB) and Imports (CIF).

Equations were estimated by OLS and t-statistics are reported in parentheses.
3. The Savings-Investment Approach

Textbooks describe the trade account identity under three different forms: exports minus imports, income minus absorption and savings minus investment. Economists' preference for using one rather than another depends on the aspects of the trade account they want to emphasize. The savingsinvestment approach is suitable for a long run analysis in which full employment is assumed. In what follows, consumption per capita is assumed to depend on permanent income per capita and to be constant, and so is savings per capita, S. Investment per capita, I, is described as an increasing function of the real price of capital, $q$, which in turn is determined in the assets market.

The diagrams below illustrate the key variables affecting the trade account. Although assumptions are simplified, the main results carry over in more complete and sophisticated settings.

In the financial markets, domestic residents face the choice among four assets: real money, real foreign bonds, real domestic bonds and equities. Assets demand depend on rates of return and wealth. Fixed exchange rates imply that the money stock is fully endogenous. Domestic residents can trade money for foreign bonds at the going foreign real interest rate, r*, and the central bank has to accommodate portfolio shifts through exchange market intervention. It follows that we do not have to worry about the composition of money and foreign bonds. The right hand panel of Diagram 1 shows the assets market equilibrium conditions, $k k$ and $b b$, under the assumption that assets are gross substitutes. The equilibrium condition in the equities market, kk , requires that the existing stock of claims to capital be willingly held. Given the capital stock, the domestic bonds stock and

Diagram 1

net foreign assets, an increase in the rate of return of domestic bonds, $r$, creates excess supply for capital. This situation therefore, requires a fall in the price of capital, $q$, to induce the public to hold a larger fraction of their wealth in the form of equities. The capital market equilibrium schedule, $k k$, reflects the negative relation between the price of capital and the return on domestic bonds. The domestic bonds market equilibrium condition, $b b$, requires that the existing stock of domestic bonds be happily held. Given the capital stock, the stock of domestic bonds and net foreign assets, an increase in the price of capital creates excess demand for bonds. This requires a fall in the domestic interest rate to Induce the public to hold a smaller fraction of their wealth in domestic bonds. The $b b$ schedule reflects this relation between $q$ and $r$.

Short run equilibrium in the assets markets sets the equilibrium price of capital, therefore determining investment, as shown in the left hand panel of Diagram 1. That Diagram depicts an initial stationary equilibrium, with balanced current account, the difference between savings and investment being zero.

Suppose that the foreign interest rate increases. This implies that the existing stocks of capital and domestic bonds will be held only if the price of capital falls and domestic interest rate increases, as shown in the right hand panel of Diagram 2. The fall in the price of capital reduces investment, thus leading to a trade account surplus, as illustrated in the left hand panel of Diagram 2. This situation corresponds to a short run equilibrium only. As time goes by, the trade account surplus accumulates into higher net foreign assets, inducing an increase in the price of capital, recovery of investment, and elimination of the trade surplus.

From the above analysis, it follows that, in the absence of main innovations in technology and preferences, the foreign interest rate appears as the main exogenous determinant of the trade account. The empirical evidence on this issue is reported in Table V. The effect of the foreign interest rate on the trade account is positive, as predicted by theory, in all equations, either when it is used by itself or in conjunction with other variables such as relative prices and relative incomes.

Notes: Exchange Rate Indices reported in Table 1 correspond to the "free" exchange rate. See notes below Table 2.A. for definition. Also observe that:
(a) Brazilian currency: On February 13, 1967, a new cruzeiro equal to 1000 old cruzeiros was introduced. The old cruzeiro was equivalent to 1000 réis. All data was calculated in new cruzeiros.
(b) Argentinian currency: During 1969, a new peso was introduced equivalent to 100 old pesos. All data was transformed in new pesos.
(c) French currency: A new franc equal to 100 old francs was introduced on January 1, 1960. All data reported in new francs.
(d) Japanese currency: Between March 2 and March 9, 1946, all Bank of Japan notes were surrendered for 1:1 conversion into new yen notes, limited to 100 yens per person.
(e) German currency: Following the 1948 currency reform, the currency exchange rate was determined for the Reichsmark. In an amendment which became effective June 21, 1948, the word Reichsmark was replaced by the term Deutsche Mark.

TABLE 2.A.
NOTES:
Variables appearing in Table 2. A. are:
$D \equiv$ cruzeiro/dollar rate in the free market
$E X \equiv$ average cruzeiro/dollar rate for exports except coffee and inclusive of subsidies.

EM $\equiv$ average cruzeiro/dollar rate for imports
$E M^{*} \equiv$ average cruzeiro/dollar rate for imports inclusive of tariffs.

Table 2 reports the free market exchange rate under column $D$ and until 1930, this is the relevant exchange rate for exports. For the same period, the same exchange rate, inclusive of tariffs is reported under column $E M^{*}$. Between 1931/33, although only the official rate is reported, a black market, tolerated by the Banco do Brasil existed as well as a rate, called cinzenta (grey) and used in a semi-official market. For the period 1934/80, the Table reports different exchange rates for exports and imports and the footnotes (1) to (18) below explain how they were calculated and the different systems in existence at different times. Exchange rates for coffee exports are not reported, nor are special regulations and taxes concerning this commodity. During the last quarter of the past century, until 1906, the Brazilian exchange rate regime was one of floating exchange rates. In 1906, the creation of the Caixa de Conversăo institutionalizes government intervention in the exchange market. Between 1906/1917, the exchange rate oscillates around the rate fixed by the Caixa de Conversâo in the free market. Although restrictions on capital flows were imposed in 1917 and the Caixa de Estabilizacâo were created in 1926 to stabilize the exchange rate, the period between 1906/1930
can be seen as one characterized by the existence of a single free market, where the government intervened through different devices (monetary and coffee policies) to keep the exchange rate at a chosen level.

Control over exchange transactions was introduced in 1931 and has been amended several times. With the 1929/30 crisis, exchange reserves disappeared, the Caixa de Estabilização was closed and monopoly of exchange transactions by the Banco do Brasil was established. In 1931/32, a black market for exchange appears and from then on, the existence of at least more than one rate is observed.

The informal system of more than one exchange rate that appeared after 1931 is officialized in 1939 with the creation of a system with three exchange rates: free, official and special (see footnotes (5), (6) and (7) for details).

By 1949, practically all imports and exports were made subject to official authorization, and up to 1953, they were subject to quotas (see footnotes (9) to (11)).

By the end of 1953, a free market was introduced as well as an auction system for imports. Under this system (1953/60), exchange certificates were auctioned for five different categories of commodities, established on the basis of their importance. This system also provided for bonuses to be paid to different categories of exports on the basis of exchange surrendered. (See notes (12), (13) and (14).)

In March 1961, the auctioning system was abolished and transactions at par value rates were discontinued. In Table 2.A., unless where explicitly specified by a footnote, the free rate applies. Par value rates used in some calculations prior to 1961 are:

| Period | Par value rate |
| :--- | :---: |
| 1934 | .021 |
| 1935 | $.0119 /$ |
| 1936 | .0118 |
| 1937 | .0114 |
| 1938 | .0176 |
| $1939 / 44$ | .01666 |
| $1945 / 46$ | .0165 |
| $1947 / 61$ | .0187 |

In March 1961, the reform of the exchange system led to three foreign exchange markets: the market of the monetary authorities, the market of the authorized banks and the manual mariket. However, the policies pursued by the authorities slowly unified the three markets by 1964. A black market for foreign excinange has existed at least in the post-war period although its relative importance seems to be minor.

Notes: (see Table 2.A. for the relevant exchange rate under respective members below)
(1) Official rate for $60 \%$ of imports and free rate for remaining $40 \%$
(2) $35 \%$ of export revenues surrendered to Banco do Brasil at the official rate; the remaining $65 \%$ sold in the free market.
(3) Due to balance of payments problems the free market was abolished in 1937. All exports surrenciered at the ofミicial rate.
(4) Offical rate plus $3 \%$ tax.
(5) Free rate plus 5\% 亡ax.
(6) $30 \%$ of export revenues surrendered at the official rate; remaining $70 \%$ sold in the free mariket.
(7) A special rate existed in this period 1940/44 mainly for tourism and payments abroad:

| 1940 | .0208 |
| :--- | :--- |
| 1941 | .0206 |
| 1942 | .0205 |
| 1943 | .0204 |
| 1944 | .0200 |

(8) The three markets regime (official, free, and special) introduced in 1939 came to an end in 1946. The exchange rate was fized between 1946/1952 and the system depended on the application of quantitative restrictions to trade and exchange transactions. A tax of $5 \%$ yields the effective selling rates reported for imports.
(9) Higher exchange rates than those reported were certainly observed: Exports proceeds were to be surrendered to authorized banks. Those banks used part of those proceeds in a parallel market. Existence of a black market was also observed.
(10) Exchange rates were certainly above the ones reported in this table due to the existence of operations called vinculadas (private compensation). The foreign exchange proceeds of certain exports could be used for the importation of goods, without being surrendered. A premium was paid by the importer to the exporter. It should also be observed that during the $1949 / 52$ period, $20 \%$ of exports proceeds were to be invested in negotiable Treasury Bills which paid $3 \%$ interest per annum and matured in 120 days.
(11) From the end of 1953 to 1960 a fluctuating free market rate applied to all invisible transactions not directly related to the movement of goods and most capital transactions.
(12) Before October 1953, a "mixing" system applied to exports. There was a list of export products permitted to benefit from the free market. Exports were divided into groups according to different percentages that could be sold in the free market. In October this arrangement was abolished and export bonuses of 5 cruzeiros velhos for coffee and 10 cruzeiros velhos for other exports was established (see Table 2.1). In August 1954 the systam of bonuses to exports was again modified (see Taile 2.1 and footnotes). For the period 1954/1958, exchange rates in Table 2.A. column DX were calculated as weighted averages of the different exchange rates for exports, excluding the category for coffee and giving a weight equal to $25 \%$ to the highest exchange rate.
(13) Under the system introduced in October 1953, exchange certificates were auctioned for Eive different categories of commodities. (See Table 2.2). In August 1057 the five categories were reduced to two.

For details see IMF: Exchange Restrictions, and Doellinger et alia (1977), Política e Estrutura das Importacōes Brasileiras, IPEA: Coleção Relatorio de Pesquisas, R. J. . The exchange rates for imports (1954/1956) under column EM are weighted averages from Table 2.1. In the period 1958/1960, they correspond to the exchange rate under the category called geral.
(14) The proceeds of all exports, except coffee, cocoa and few others were surrendable at the free market rate, but exporters would receive cash only to the extent of 130 cruzeiros velhos per dollar. For the balance they would receive notes of the Banco do Brasil with six months' maturity and interest of $6 \%$ per annum. Given that the inflation rate was $30 \%$, the exchange rate for exporters was below the free market rate.
(15) The auctioning of exchange was abolished and exchange to pay for imports was to be obtained in the free market. The importer was required to purchase 150 -day bills and to pay a premium. Deposit requirements for imports, introduced in April 1961 were modified in different periods. In August 1964, a tax of $20 \%$ financial charge was introduced, raised to $30 \%$ in September, and reduce to $10 \%$ in December. The effective exchange rates for imports net of tariffs reported for the period 1961/66 were calculated by Maria Helena Horta (1982), "Import Equations," research being developed at IPEA, Rio de Janeiro.
(16) Includes subsidies. For 1964/77, the subsidy rates come from Cardoso (1980). "Incentivos às exportaçôes de manufaturas: Série histórica", Revista Brasileira de Economia, 34 (2). The subsidy rates for 1978/79 were assumed to be the same prevailing in 1977. Subsidies were abolished in December 1979 and slowly reintroduced by late 1980, beginning of 1981.
(17) A system of advance import deposit requirements was reintroduced in July 1975 and modified on different occasions until it was suspended in December 1979. The effective exchange rates net of tariffs for that period come from Rosa J. A., et allia, Alguns Aspectos da Política Tarifária Recente no Brasil, CECEX: 1979.

| 1959 - Jan./June | . 060 | . 070 | . 100 |  |  |
| 1959 - July/Dec. |  |  |  |  |  |

NOTES:

Oct. 1953 - Export bonuses of 5 cruzeiros velhos per dollar of coffee and 10 cruzeriros velhos per dollar of other exports were introduced.

Aug. 1954 - The bonuses of 5 and 10 cruzeiros velhos now applied to only 80 percent of the value of exports instead of 100 percent as previously. In the remining $20 \%$, a premium equal to the difference between the official rate of exchange and the average free market rate for the previous day was to be paid.

Jan. 1955 - Exports were divided into four categories and the premiums paid on export proceeds were fixed according to the type of commodity involved and the currency received. Category I consisted only of coffee. Data reported on Table 2.1 refers to bonus for exports against convertible currencies.

Feb. 1955 - Coffee export proceeds were granted category II export bonuses.

June 1957 - A bonus not to exceed 36 cruzeiros velhos per dollar would be paid to exporters of textile products.

June 1958 - Export proceeds were reclassified and the fixed bonuses were revised.

The special exchange rate for exports of textiles was eliminated.

Oct 1958 - Proceeds of exports not in Categories I through IV were permitted to be negotiated in the free market.

Jan
1959 - Export proceeds were reclassified in three categories and bonuses were revised.

April, June, 1959 - Proceeds of exports of sugar, cotton and meat were to be surrendered at the free market rate.

July 1959 - Export proceeds were reclassified and bonuses were revised.

Dec. 1959 - Proceeds of all exports except coffee beans, roasted coffee, cocoa, castor beans and crude mineral oil were to be surrendered at the free market rate, but exporters would receive cash only to the extent of 130 cruzeiros velhos per dollar. For the balance they would receive notes of the Banco do Brasil with 6 months maturity and interest of 6 percent per annum.

Sources: Tables 1, 2, 3, 4, 5, and 7

NOTES:
FX $\equiv$ Real Effective Exchange Rate. It uses export weights and exchange rates in the free market.

$$
\sum^{9} W_{i} P_{i} E_{i}
$$

$F X \equiv \frac{i=1}{P}$
where: $W_{i} \equiv$ export weight of country $i$ (see Table 3.A.)
$P_{i} \equiv$ price index of country $i \quad$ (see Table 5.A.)
$E_{i} \equiv$ index for the exchange rate expressed as cruzeiros per currency of country $i$ (see Table 1.A.)

P $\equiv$ Brazilian price index

FM $\equiv$ Real Effective Exchange Rate. It uses import weights and exchange rates in the free market.

$$
\sum^{9} W_{i} P_{i} E_{i}
$$

$F M \equiv \frac{\mathrm{i}=1}{\mathrm{P}}$
where $M_{i} \equiv$ import weights of country i (see Table 3)
$D \equiv$ Real dollar exchange Rate. It uses the cruzeiros per dollar rate (E ${ }_{u s}$ ) in the free market.
$D \equiv \frac{\mathrm{P}_{\mathrm{us}} \mathrm{E}_{\mathrm{us}}}{\mathrm{P}}$

## Correlation Matrix (1907-1980)

|  | FX | D | FM |
| :--- | ---: | ---: | ---: |
| FX | 1.000 |  |  |
| D | .926 | 1.000 |  |
| FM | .945 | .957 | 1.000 |

$D X \equiv$ Real dollar exchange rate for exporters. It uses an index, $I$ ( $1957 \equiv 100$ ), which was calculated using the rate of cruzeiros'received for one dollar of exported good, reported in Table 2.A. as EX.
$D X \equiv \frac{\mathrm{P}_{\text {us }} \mathrm{I}_{\mathrm{x}}}{\mathrm{P}}$
$D M \equiv$ Real dollar exchange rate for importers. It uses an index, $I_{\text {( }}$ (1975 $\equiv$ 100), which was calculated using the rate of cruzeiros paid fyr one dollar of imported good reported in Table 2.A. as EM.
$D M \equiv \frac{P_{\text {us }} I_{M}}{P}$

Correlation Matrix (1907-1980)

|  | D | DX | DM |

Sources: Boletim do Banco Central do Brasil and Anuário Estatistico, several issues.

For the pre-war years, the share of oil in total imports was assumed to be negligible; for the years $1946 / 49$ the share was assumed to be $10 \%$. Actual shares for $1950 / 80$ are available from sources above.

## Notes and Sources:

The real interest rate is defined as: $r^{*}=i^{*}-\pi^{*}$, where $i *$ is the yields percent per annum on U.S. Treasury securities, 10 years maturity for the years 1919/1980 and the yields on Railroad Bonds for the years 1908/1918. The sources for the nominal interest rates are: Economic Report of the President and Historical Statistics of U.S., U.S. Department of Commerce. The U.S. inflation rate was calculated using the prices reported in Table 5.A.

Column 2 reports the difference between the Brazilian real GNP growth rate and the U.S. real GNP growth rate. Sources are: Claudio Haddad, Crescimento do Produto Real no Brasil, 1900-47 (for the years 1908-1940); Malan et.al., opus cit., (for the years 1940-52) and Conjuntura Econômica, several issues. For U.S. sources are: U.S. Historical Statistics; Federal Reserve Bank of St. Louis and the Economic Report of the Presidenr.
