Abstract

This paper develops a new test of orthogonality based on a zero restriction on the covariance between the dependent variable and the predictor. The test provides a useful alternative to regression-based tests when conditioning variables have roots close or equal to unity. In this case standard predictive regression tests can suffer from well-documented size distortion. Moreover, under the alternative hypothesis, they force the dependent variable to share the same order of integration as the predictor, whereas in practice the dependent variable often appears stationary while the predictor may be near-nonstationary. By contrast, the new test does not enforce the same orders of integration and is therefore capable of detecting alternatives to orthogonality that are excluded by the standard predictive regression model. Moreover, the test statistic has a standard normal limit distribution for both unit root and local-to-unity conditioning variables, without prior knowledge of the local-to-unity parameter. If the conditioning variable is stationary, the test remains conservative and consistent. Thus the new test requires neither size correction nor unit root pre-test. Simulations suggest good small sample performance. As an empirical application, we test for the predictability of stock returns using two persistent predictors, the dividend-price-ratio and short-term interest rate.

Part of this work was completed while the authors were visiting the Cowles Foundation and we gratefully acknowledge their hospitality. Maynard thanks the SSHRC for research funding.
1 Introduction

This paper develops a new test of orthogonality based on a zero restriction on the covariance between the dependent variable and the predictor. When the predictor is stationary, this zero-covariance restriction is identical to the restriction imposed in commonly employed predictive regressions, in which the dependent variable \( y_t \) is regressed on the predictor \( x_{t-1} \). However, when the predictor has a root close or equal to unity, the predictive regression forces the dependent variable to have the same order of integration as the predictor under the alternative hypothesis. In other words, the dependent variable has a (near) unit root component that cointegrates with the predictor. Since there is often good reason to think that the dependent variable is stationary, this regression model may not provide the only relevant alternative to orthogonality. The zero-covariance restriction proposed here allows for the detection of empirically relevant alternatives to orthogonality, in which the conditioning variable (e.g. interest rates, dividend yields) may be either stationary, near nonstationary, or \( I(1) \), but the dependent variable (e.g. stock returns) is presumed stationary.

Predictive regression tests are also known to suffer from substantial size distortion when regressors have roots near unity and are predetermined but not strictly exogenous (e.g. Mankiw and Shapiro (1986), Cavanagh et al. (1995), and Stambaugh (1999)). This size distortion is known to depend on the local to unity parameter and is not solved by two stage inference based on unit root pre-test (Cavanagh et al. (1995), Elliott (1998)). Another advantage of the covariance based approach is that it yields a single asymptotic t-type test that has correct size when the conditioning variable is modelled as either a unit root or local to unity process (with finite local-to-unity parameter \( c \)). The test has conservative size, but remains consistent when the conditioning variable is stationary. It thus provides a sound basis for inference without reference to prior knowledge, estimates, or pre-tests regarding the size of the root.

The size distortion problem mentioned above has recently generated an active literature aimed at correcting inference in regression-based predictive tests. In a local-to-unity context, solutions of this type include bounds procedures (Cavanagh et al. (1995), Torous et al. (2005), Valkanov (2003), Campbell and Yogo (2006)), re-formulation of the problem as a stationarity test on \( y_t \) (Wright (2000), Lanne (2002)), and conditionally optimal inference employing sufficient statistics (Jansson and Moreira (2006)). Other solutions, often in more tightly parametrized models, include finite sample size corrections (Stambaugh (1999), Lewellen (2004)), augmented regression methods (Amihud and Hurvich (2004), Amihud et al. (2004)), Bayesian approaches (Elliott and Stock (1994), Stambaugh (1999), Lewellen (2004)), and re-sampling approaches (Nelson and Kim (1993), Goetzmann and Jorion (1993), Wolf (2000)).

Our test shares the attractive feature of the procedures described above in that it maintains good size when the predictor is persistent. This is obtained without size correction, pretest, or information on the local-to-unity parameter \( c \). On the other hand, our test differs from the size-corrected regressions in that it is based on a
different parameter restriction. As explained in the paragraphs below, this allows us to consider alternatives not covered by the regression model, including unbalanced alternatives in which $y_t$ remains stationary despite $I(1)$ or local-to-unity behavior in $x_t$.

In this way, our approach differs somewhat fundamentally from that taken in much of the previous literature. The traditional framework, in which $x_t$ is stationary and, under the alternative, $y_t$ is a constant linear function of $x_{t-1}$, has intuitive appeal in many applications and is often consistent with economic or financial theory. For example, if under a failure of rational expectations, asset prices temporarily deviate from their fundamental value, the levels of valuation measures such as the earnings or dividend price ratio may have some predictive power for future market corrections. Thus, even as the recent literature has relaxed the stationarity assumptions on $x_t$ it has generally maintained alternative specifications in which $y_t$ depends linearly on $x_{t-1}$. A major advantage of this approach is that it has allowed researchers to re-examine exactly the same alternatives that have been influential in the previous literature. Thus this branch of the econometrics literature has made very important and useful contributions in both econometrics and empirical finance.

On the other hand, once we allow the possibility that $x_t$ is (near) nonstationary, there is also an argument in favor of broadening the alternative to allow for certain more general forms of predictability. The reason is that, under the fixed-coefficient linear alternative discussed above, a (near) permanent component to $x_t$ implies a near permanent component to $y_t$. However, $y_t$ is typically a financial return and empirically such returns generally show little serial correlation. This is apparent on comparing the behavior of the real stock return series shown in the top panel of Figure 1 with that of the two persistent predictors, the log-dividend price ratio and treasury bill rate, shown in the bottom two panels. Likewise, a stationary return may arguably be more appealing from the perspective of economic or financial theory. For example, in a standard rational expectations model, the predictable component in the excess return $(E_{t-1}y_t)$ reflects a time varying risk premium, so that a stationary risk premium would imply a stationary return series. By explicitly testing a covariance restriction rather than a regression coefficient restriction we widen the set of alternatives to include those in which $y_t$ remains predictable yet stationary even when $x_t$ has a (near) unit root. These alternatives are not permitted under the regression based tests that have traditionally been employed, even when size-corrected.

Naturally, this is not the only class of alternatives that is consistent with the empirical observation that $x_t$ typically appears (near) nonstationary whereas $y_t$ appears (near) stationary. For example, it may be argued that local $o(n^{-1/2})$ versions of the traditional linear regression alternative sufficiently dampen the nonstationary component so as to be consistent with near-stationary returns. While our covariance test is also shown to be consistent against such alternatives, this is not the primary alternative that it was designed to capture and, consequently, it does not match the regression based test in providing consistency against local regression alternatives of

---

1 A full description of the data employed for these figures is provided in Section 6.
order $n^{-1}$. Thus the covariance based test proposed here must properly be considered as a complement rather than a substitute for existing regression based tests.

As in our approach, there are other tests of orthogonality that are based on alternative procedures to predictive regression. In this vein, Campbell and Dufour (1995, 1997) provide exact tests of orthogonality using non-parametric sign and sign rank tests, while Toda and Yamamoto (1995) (see also Saikkonen and Lütkepohl (1996)) have also shown that, by choosing the lag order sufficiently large, one can estimate VARs formulated in levels and test general parameter restrictions even if the order of integration of the process is unknown.

There is also a recent literature seeking to model the regression imbalances ($y_t \sim I(0), x_t$ near $I(1)$) commonly observed in practice. Marmer (2004) suggests a model in which $y_t$ appears as $I(0)$ but has a predictable component formulated as a nonlinear function of a unit root process. By rescaling the innovation variance of $x_t$ by $\sqrt{n}$, Moon et al. (2004) model $y_t$ as the sum of a small but persistent regressor and a large white noise error term. In a more general context, Phillips (2005) suggests a coordinate cointegration approach in terms of $L^2[0,1]$ basis functions that allows for the modelling of relationships between stochastically imbalanced variables. Our framework is arguably simpler in that we allow for an imbalance between $y_t$ ($I(0)$) and $x_t$ ($I(1)$), in which $y_t$ is still predictable based on the past history of $x_t$, within the standard linear process setting.

As an empirical application, we revisit well-known orthogonality tests involving the prediction of stock returns using dividend-yields and interest rates. We find little evidence for predictability in the case of the dividend-price ratio where regression tests may suffer substantial size distortion. However, the covariance-based tests confirm the modest evidence of predictability found using the interest rate.

The remainder of the paper is organized as follows. Section 2 outlines our basic approach. Section 3 introduces the kernel-based estimator of the covariance between $y_t$ and $x_{t-1}$ and demonstrates its asymptotic behavior when $x_t$ is $I(1)$, $I(0)$, and local-to-unity. Section 4 discusses inference based on the covariance estimate, and Section 5 reports some simulation results. The empirical application is reported in Section 6, and Section 7 concludes. Proofs are given in Appendix A (Section 8) and Appendix B (Section 9) collects some technical results.

2 Covariance-based orthogonality testing

We consider a test of the orthogonality or non-predictability condition

$$H_0 : E \left[ y_t \mid I_{x,t-1} \right] = 0,$$

where $I_{x,t-1} = \sigma(x_{t-1}, x_{t-2}, x_{t-3}, \ldots)$ denotes the information contained in the past history of $x_t$. Several common empirical applications may be cast in this form, including tests of stock return predictability, forward rate unbiasedness, the permanent

$^2$See Maynard (2006) for an application to the forward rate unbiasedness test.
income hypothesis, the expectations hypothesis of the term structure, and the constant real interest rate hypothesis.\textsuperscript{3}

In practice one often tests the simpler restriction implied by (1):

\[
\text{cov}(y_t, x_{t-1}) = 0.
\]  

Typically this is accomplished by modeling \( y_t \) as a linear function of \( x_{t-1} \)

\[
y_t = \beta_0 + \beta_1 x_{t-1} + \varepsilon_t, \quad E[\varepsilon_t|I_{x,t-1}] = 0,
\]  

estimating \( \beta_1 \) by OLS, and testing the restriction \( \beta_1 = 0 \). In doing so, one estimates

\[
\hat{\beta}_1 = \frac{\text{cov}(y_t, x_{t-1})}{\text{var}(x_{t-1})}
\]

by its sample analog \( \hat{\beta}_1 = \hat{\text{cov}}(y_t, x_{t-1})/\hat{\text{var}}(x_{t-1}) \) and tests \( \beta_1 = 0 \).

Such tests were traditionally formulated with stationary regressors in mind, in which case testing \( \beta_1 = 0 \) is equivalent to testing \( \text{cov}(y_t, x_{t-1}) = 0 \) because \( \text{var}(x_{t-1}) \) in (4) is finite. However, it has come to be understood that many of the regressors, such as interest rates, dividend-price ratios, and forward premia are highly persistent and may be well characterized by roots near unity (e.g. Mankiw and Shapiro (1986), Stambaugh (1999)). Moreover, in practice there is usually considerable uncertainty regarding the size of the largest root in the regressor, with confidence intervals frequently containing both one and values considerably below unity. On the other hand, it often occurs that \( y_t \) (e.g. a stock or exchange rate return) appears stationary on empirical and/or a priori theoretical grounds.

This suggests a potential imbalance between the stationary dependent variable and possibly near \( I(1) \) regressor in (3), which may cause some difficulty when (3) is used to test for the orthogonality condition in (1). Suppose, for example, that \( x_t \) is \( I(1) \) and \( y_t \) is \( I(0) \). In this case, only one value of \( \beta_1 \), i.e. \( \beta_1 = 0 \), can satisfy the regression model in (3), because there cannot exist a simple linear relationship between \( I(0) \) and \( I(1) \) variables. Thus, were to take the model in (3) literally, by forcing \( \beta_1 = 0 \) this imbalance would itself imply that \( y_t \) was unpredictable.

Moreover, when \( y_t \) is \( I(0) \) and \( x_t \) is \( I(1) \) or near \( I(1) \), the equivalence between a test of \( \beta_1 = 0 \) and a test of \( \text{cov}(y_t, x_{t-1}) = 0 \) breaks down. This is due to the fact that \( \hat{\beta}_1 = \hat{\text{cov}}(y_t, x_{t-1})/\hat{\text{var}}(x_{t-1}) \) converges to zero in probability regardless of whether the restriction \( \text{cov}(y_t, x_{t-1}) = 0 \) holds, simply because \( \hat{\text{cov}}(y_t, x_{t-1}) = O_p(1) \), while \( \hat{\text{var}}(x_{t-1}) = O_p(n) \). In other words, tests based on \( \beta_1 \neq 0 \) are not designed to detect alternatives to (1) in which \( y_t \) is stationary and \( x_t \) is nonstationary. In fact, under the alternative implied by \( \beta_1 \neq 0 \) in (3), when \( x_t \) is \( I(1) \), \( y_t \) is both nonstationary and cointegrated with \( x_t \).

Outside the simple regression framework in (3), the fact that \( x_t \) and \( y_t \) have different orders of integration does not in itself imply that \( y_t \) is unpredictable by the

\textsuperscript{3}See Mankiw and Shapiro (1986) and references therein.
past history of $x_t$. In fact, when $y_t$ is $I(0)$ and $x_t$ is $I(1)$ a more general DGP is given by the joint linear process

$$
\begin{bmatrix}
y_t \\
\Delta x_t
\end{bmatrix} = A(L) \varepsilon_t = \sum_{j=0}^{\infty} A_j \varepsilon_{t-j}, \quad \sum_{j=0}^{\infty} j ||A_j|| < \infty, \quad \varepsilon_t \sim \text{i.i.d.}(0, I_2),
$$

(5)
in which (1) holds only for very specific parameter values.\(^4\) One economic interpretation of this alternative is that the past history of $x_t$ has explanatory power for the stationary risk premium $(E_{t-1}y_t)$ and thus predictive power for the excess return $y_t$.

The covariance condition in (2) allows for a more flexible test than the restriction that $\beta_1 = 0$ in (3). Clearly, when $x_t$ is stationary and $\text{var}(x_{t-1})$ is finite the two conditions are equivalent (see (4)). In the more interesting case, in which $y_t$ is $I(0)$ but $x_t$ is $I(1)$ and properly initialized, $\text{cov}(y_t, x_{t-1})$ is time varying, but still well-defined. Likewise, the orthogonality condition in (1) continues to imply that $\text{cov}(y_t, x_{t-1}) = 0$ for all $t$. Finally, when (1) fails, this restriction is typically violated, i.e. $\text{cov}(y_t, x_{t-1}) \neq 0$ in general. In other words, the restriction $\text{cov}(y_t, x_{t-1}) = 0$ admits a wide class of alternatives to (1), including alternatives not covered by a test of $\beta_1 = 0$, in which $y_t$ is stationary but $x_t$ is $I(1)$, as in (5).

Therefore, we propose to test directly the condition $\text{cov}(y_t, x_{t-1}) = 0$ instead of testing $\beta_1 = 0$. However, since $\text{cov}(y_t, x_{t-1})$ depends on $t$ when $x_t$ is $I(1)$, we base our test on the limiting covariance, which we define as $\lim_{t \to \infty} \text{cov}(y_t, x_{t-1})$. When $y_t$ and $x_{t-1}$ are stationary the limiting covariance is simply the covariance between $y_t$ and $x_{t-1}$. When $y_t$ is $I(0)$ and $x_{t-1}$ is $I(1)$ it provides an asymptotic approximation to their covariance. Since the orthogonality condition (1) implies that $\text{cov}(y_t, x_{t-1}) = 0$ for all $t$ it also imposes the testable condition that $\lim_{t \to \infty} \text{cov}(y_t, x_{t-1}) = 0$, regardless of whether $x_t$ is $I(0)$ or $I(1)$. On the other hand, as explained below, the limiting covariance is generally non-zero when (1) fails, even when $y_t$ is $I(0)$ and $x_t$ is $I(1)$, as in (5).

The limiting covariance between $y_t$ and $x_{t-1}$ may also be usefully reformulated in terms of the one-sided long-run covariance between $y_t$ and $\Delta x_{t-1}$. This interpretation is helpful in establishing its properties. It also motivates the kernel estimator that we employ later. Assume $x_0 = 0$ for simplicity and that $(y_t, \Delta x_t)$ is covariance stationary. Because $x_{t-1}$ may be written as the sum of its past differences as $x_{t-1} = \sum_{h=1}^{t-1} \Delta x_{t-h}$, the covariance takes the form

$$
\text{cov} \left( y_t, x_{t-1} \right) = \sum_{h=1}^{t-1} \text{cov} \left( y_t, \Delta x_{t-h} \right),
$$

and the limiting covariance may be expressed as

$$
\lambda_{y, \Delta x} \equiv \lim_{t \to \infty} \text{cov}(y_t, x_{t-1}) = \lim_{t \to \infty} \sum_{h=1}^{t-1} \text{cov} \left( y_t, \Delta x_{t-h} \right) = \sum_{h=1}^{\infty} \text{cov} \left( y_t, \Delta x_{t-h} \right),
$$

(6)

\(^4\)Since we impose no a priori restriction on the largest root of $x_t$, we also consider the DGPs in which $(y_t, x_t)$ follows a joint linear process, as well as local-to-unity models for $x_t$.\]
which is well-defined so long as \( \sum_{h=0}^{\infty} |\text{cov}(y_t, \Delta x_{t-h})| < \infty \). When \( x_t \) is stationary, (6) simplifies to \( \lambda_{y,\Delta x} = \lim_{t \to \infty} \text{cov}(y_t, x_{t-1}) = \text{cov}(y_t, x_{t-1}) \). Finally, if \( x_t \) is modelled local-to-unity as
\[
x_t = \left(1 + \frac{c}{n}\right)x_{t-1} + u_t, \quad t = 1, 2, \ldots, n, \quad n = 1, 2, \ldots, c < 0,
\]
with \( x_t \equiv 0 \) for \( t \leq 0 \), then as shown in Appendix A, (6) takes the form
\[
\lambda_{y,\Delta x} = \lim_{t \to \infty} \text{cov}(y_t, x_{t-1}) = \sum_{h=1}^{\infty} \text{cov}(y_t, u_{t-h}) + O\left(n^{-1}\right).
\]
and is well-defined when \( \sum_{h=1}^{\infty} h|\text{cov}(y_t, u_{t-h})| < \infty \).

The (limiting) covariance cannot be consistently estimated by the sample covariance of \( y_t \) and \( x_{t-1} \), which converges to a random variable when \( x_t \) is \( I(1) \). Instead, we estimate (6) by a standard kernel estimator, which is consistent for both stationary and nonstationary \( x_t \), without the necessity of pretesting or estimating the root of \( x_t \). This feature may be useful in applied work, as it is often difficult to distinguish with confidence between \( I(0) \) and \( I(1) \) alternatives. A second desirable property of the estimator is that it is shown to have the same limit distribution for all finite values of the local to unity parameter \( c \). This allows us to avoid two-stage inference procedures, such as Bonferroni bounds, that are often necessitated by the lack of a consistent time-series estimator for \( c \). We construct a large sample test, based on a single test statistic with a limiting standard normal distribution under both unit root and local to unity assumptions. No bias corrections or other adjustments are required. The test is shown to remain conservative and consistent when \( x_t \) is stationary.

Unlike the regression model in (3), our test is designed to have power against a general class of alternatives to (1) under which \( y_t \) is stationary and predictable based on the past history of \( x_{t-j} \), \( j \geq 1 \), regardless of whether \( x_t \) is \( I(0) \), \( I(1) \), or local to unity. For example, in the unbalanced case given by (5), the limiting covariance is given by \( \lambda_{y,\Delta x} = \sum_{j=1}^{\infty} \sum_{h=0}^{\infty} A_j^2 (A_j^{-h})' \), where \( A_j \) denotes the \( i \)th row of \( A_j \), and is generally non-zero when \( y_t \) may be predicted by past \( x_t \). For instance, a simple example is
\[
y_t = \gamma_0 + \gamma_1 (x_{t-1} - x_{t-2}) + \varepsilon_{1t}, \quad \gamma_1 \neq 0,
\]
in which case \( \lambda_{y,\Delta x} = \gamma_1 \sum_{h=1}^{\infty} E(\Delta x_{t-1} \Delta x_{t-h}) \). Our test also remains generally consistent against the regression alternative specified in (3) with \( \beta_1 \neq 0 \). By contrast, tests based on \( \hat{\beta}_1 \) are not designed to have power against alternatives such as (5) or (9), in which \( y_t \) is \( I(0) \), but \( x_t \) may be \( I(1) \).

On the other hand, tests based on \( \hat{\beta}_1 \) naturally have better power if (3) is the correctly specified model. Likewise, if (9) is the correct model, then a regression of \( y_t \) on \( \Delta x_{t-1} \) will of course have better power. However, in practice it is often difficult to determine a priori which model is correct and confidence intervals on the largest

\(^5\)When \( x_0 \neq 0 \), \( \text{cov}(y_t, x_{t-1}) \) is defined as \( \sum_{h=1}^{t-1} \text{cov}(y_t, \Delta x_{t-h}) + \text{cov}(y_t, x_0) \) and (6) continues to apply under the relatively weak and reasonable assumption that \( \lim_{t \to \infty} \text{cov}(y_t, x_0) \to 0 \).
root of $x_t$ are typically wide. Even if we restrict ourselves to the simplest parametric models in (3) and (9), the model selection exercise is non-trivial, as it involves a unit root pre-test that may complicate the second-stage inference. Two-step procedures that involve unit-root pretesting are known to suffer from size distortion when the roots may be close to unity (e.g. Cavanagh et al. (1995, Table 1)).

3 Estimation of limiting covariance

In this section, we develop an estimator of the limiting covariance between $y_t$ and $x_{t-1}$, as defined in (6), and derive its asymptotic properties. First we consider the case when $x_t$ is $I(1)$.

Assumption A

$(y_t, \Delta x_t)$ is generated by

$$z_t = \left( \begin{array}{c} y_t \\ \Delta x_t \end{array} \right) = A(L) \varepsilon_t = \sum_{j=0}^{\infty} A_j \varepsilon_{t-j}, \quad \sum_{j=0}^{\infty} j^\delta |A_j| < \infty, \quad \delta > 1; \quad (10)$$

$$\varepsilon_t \sim \text{i.i.d.} (0, I_2), \quad \text{with finite fourth moment,}$$

$$\sum_{h=-\infty}^{\infty} |h|^\delta \|\Gamma(h)\| < \infty, \quad \Gamma(h) = \begin{bmatrix} \Gamma_{yy}(h) & \Gamma_{y\Delta x}(h) \\ \Gamma_{\Delta yx}(h) & \Gamma_{\Delta x\Delta x}(h) \end{bmatrix} = E z_t z_t',$$

where $|A| = (\text{tr}(A' A))^{1/2}$ is the Euclidean norm of a matrix $A$.

The assumption that $\text{var}(\varepsilon_t) = I_2$ is innocuous because we do not normalize the elements of $A_j$. Note that under these assumptions $y_t$ is stationary, although $x_t$ may be $I(1)$. However, the orthogonality condition (1) holds only under particular parameter choices, for example, when the off-diagonal elements of $A_j$ are zero for all $j > 0$. The limiting covariance between $y_t$ and $x_{t-1}$, which, under the above assumptions, may be expressed as $\lambda_{y, \Delta x} = \lim_{t \to \infty} \text{cov}(y_t, x_{t-1}) = \sum_{h=1}^{\infty} \text{cov}(y_t, \Delta x_{t-h}) = \sum_{h=1}^{\infty} \sum_{j=0}^{\infty} A_j A_j' (A_{j-h}^2)'$ is zero when (1) holds, but is generally non-zero otherwise.

It is well known that when $x_t$ is $I(1)$ the sample covariance between $y_t$ and $x_{t-1}$ converges to a random variable. Thus we propose instead to estimate the limiting covariance between $y_t$ and $x_{t-1}$ based on its reformulation in (6). This expression suggests the following one-sided kernel covariance estimator

$$\hat{\lambda}_{y, \Delta x} = \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \hat{\Gamma}_{\Delta yx}(h); \quad \hat{\Gamma}_{\Delta yx}(h) = \frac{1}{n} \sum_{t=h+1}^{n} y_t \Delta x_{t-h}, \quad (11)$$

where $m$ is the bandwidth and $k(x)$ is the kernel.\(^6\)

\(^6\)We use $k((h-1)/m)$ instead of $k(h/m)$ in the definition $\hat{\lambda}_{y, \Delta x}$ so that the leading term, $\hat{\Gamma}_{\Delta yx}(1)$, is multiplied by 1, instead of $k(1/m)$, leading to a smaller bias, especially when $m$ is small.
Assumption K
The kernel $k(x)$ is continuous at $x = 0$ and uniformly bounded with $k(0) = 1$, $\int_0^\infty k(x)x^2dx < \infty$, and $\lim_{x \to 0+} \frac{1-k(x)}{|x|^q} = k_q < \infty$ with $\delta \geq q$, where $\bar{k}(x) = \sup_{y \geq x} |k(y)|$.

Assumption M
$$\frac{1}{m} + \frac{m^q}{n} \to 0 \text{ as } n \to \infty.$$  

Assumption K is satisfied by the Bartlett kernel with $q = 1$. Other kernels such as the Parzen kernel, Tukey-Hanning kernel, and Quadratic Spectral kernel satisfy Assumption K with $q = 2$. The condition $\int_\infty^0 \bar{k}(x)x^2dx < \infty$ is necessary to rule out pathological cases where the convergence of $m^{-1}\sum_{h=1}^{n-1} k(h/m)$ to $\int_0^\infty k(x)dx$ fails, for instance $k(x) = 1$ for any integer $x$ but $k(x)$ is the same as the QS kernel otherwise. See Lemma 1 of Jansson (2002) and the discussion therein.

Let $f_{yy}(\lambda)$ denote the spectral density of $y_t$, let $f_{\Delta xy}(\lambda)$ denote the cross-spectral density between $\Delta x_t$ and $y_t$, and define $f_{y\Delta x}(\lambda)$ and $f_{\Delta x\Delta x}(\lambda)$ analogously. The following lemma provides the asymptotic bias and variance of $\hat{\lambda}_{y,\Delta x}$ and shows its consistency.

**Lemma 1** If Assumptions A, K and M hold, then

(a) $\lim_{n \to \infty} m^q E(\hat{\lambda}_{y,\Delta x} - \lambda_{y,\Delta x}) = -k_q \sum_{h=1}^\infty \Gamma_{\Delta xy}(h) h^q$,

(b) $\lim_{n \to \infty} nm^{-1} var(\hat{\lambda}_{y,\Delta x}) = V \equiv 4\pi^2 f_{yy}(0) f_{\Delta x\Delta x}(0) \int_0^\infty k^2(x) dx$,

(c) $\hat{\lambda}_{y,\Delta x} \to_p \lambda_{y,\Delta x}$ as $n \to \infty$.

The proof of part (a) is omitted because it is the same as that of Theorem 10 in Hannan (1970, p. 283). Part (b) is a one-sided version of Theorem 9 of Hannan (1970, p. 280).

**Remark 1** $\lambda_{y,\Delta x} \neq 0$ provided that $\sum_{h=1}^\infty \sum_{j=0}^\infty A_j^2 (A_j^2 - h)^q \neq 0$.

**Remark 2** It is well known that the limiting variance of the two-sided long-run covariance estimate between $y_t$ and $\Delta x_t$ is given by $4\pi^2 \int_{-\infty}^{\infty} k^2(x) dx \{f_{yy}(0)f_{\Delta x\Delta x}(0) + [f_{y\Delta x}(0)]^2\}$. Hence, in the special case where $y_t = \Delta x_t$, $V$ is $1/4$ of the limiting variance for the two-sided case.

**Remark 3** From Lemma 1, the asymptotic mean squared error is minimized by choosing $m$ such that

$$m^* = \left(2q k_q^2 \left(\sum_{h=1}^\infty \Gamma_{\Delta xy}(h) h^q \right)^2 n / V \right)^{1/(2q+1)}.$$
Assuming \( k(x) \) is symmetric, we can rewrite \( m^* \) as

\[
m^* = \left( q k_0^2 \alpha(q) n / \int_{-\infty}^{\infty} k^2(x) \, dx \right)^{1/(2q+1)},
\]

(12)

\[
\alpha(q) = \frac{4 ((2\pi)^{-1} \sum_{h=1}^{\infty} \Gamma \Delta xy(h) h^q)^2}{f_{yy}(0) f_{\Delta x \Delta x}(0)},
\]

giving expressions similar to those in Andrews (1991, pp. 825, 830). If \( m \) is chosen optimally, then the rate of convergence is \( n q / (2q+1) \).

Interestingly, when the truncated kernel \( (k(x) = 1, |x| \leq 1, 0 \text{ otherwise}) \) is employed, we obtain \( \hat{\lambda}_{y, \Delta x} = \hat{\text{cov}}(y_t, x_{t-1} - x_{t-m-1}) \), which equals the numerator of the coefficient in the regression of \( y_t \) on \( x_{t-1} - x_{t-m-1} \). For fixed \( m = 1 \) this simplifies to a regression of \( y_t \) on \( \Delta x_{t-1} \). A test based on such a regression might appear simpler than the one proposed here. However, this would test only the restriction \( \text{cov}(y_t, \Delta x_{t-1}) = 0 \), which is quite distinct from \( \lim_{t \to \infty} \text{cov}(y_t, x_{t-1}) = 0 \), the restriction tested by our procedure. The requirement that \( m \to \infty \) in Assumption M is necessary for the consistent estimation of the limiting covariance between \( y_t \) and \( x_{t-1} \), without which a valid test of the restriction in (2) is not possible.

On the other hand, one might also consider a test based on the regression of \( y_t \) on \( x_{t-1} - x_{t-m} \), while allowing \( m \to \infty \). Unfortunately, not only would the choice of \( m \) pose a difficulty, but more fundamentally, such a regression entails a drawback similar to that of the regression of \( y_t \) on \( \Delta x_{t-1} \). In particular, when \( y_t \) is \( I(0) \) and \( x_t \) is \( I(1) \), it follows from Lemma 1 and the divergence of \( \hat{\text{var}}(x_{t-1} - x_{t-m-1}) \) that the regression coefficient converges to 0 in probability regardless of whether or not (1) holds.

3.1 The limit distribution when \( x_t \) is \( I(1) \)

It is well known that the estimator of the two-sided long-run covariance between \( y_t \) and \( \Delta x_t \) has a normal limiting distribution. However, currently there are no corresponding distributional results for the one-sided long-run covariance estimator, partly because its analysis is substantially more involved than that of its two-sided counterpart. To see why, let \( \Sigma \) and \( \Lambda \) denote the contemporaneous covariance and the one-sided long-run covariance matrix, so that

\[
\Sigma = E[z_t z_t'] = \Gamma(0), \quad \Lambda = \sum_{h=1}^{\infty} \Gamma(h) = \begin{bmatrix} \Lambda_{yy} & \Lambda_{y \Delta x} \\ \Lambda_{\Delta x y} & \Lambda_{\Delta x \Delta x} \end{bmatrix},
\]

\[
\sum_{h=-\infty}^{\infty} \Gamma(h) = 2\pi f_z(0) = \Sigma + \Lambda + \Lambda'.
\]

The limiting distribution of spectral density estimators has been studied widely in the statistics literature and it is well known that (e.g. Hannan, 1970, Theorem 11, p.289)

\[
\sqrt{\frac{n}{m}} \left( \sum_{h=-n+1}^{n-1} k \left( \frac{h}{m} \right) \hat{\Gamma}(h) - 2\pi f_z(0) \right) \to_d N(0, \Phi),
\]

10
where $\Phi$ is finite. Let the one-sided long-run covariance estimate be $\hat{\Lambda} = \sum_{h=-1}^{n-1} k(h/m) \hat{\Gamma}(h)$, where $\Gamma(h)$ is the $h$th sample autocovariance of $z_t$. Deriving the limiting distribution of the diagonal elements of $\Lambda$ is easy, because we can use the identities

$$\Lambda_{yy} = \sum_{h=1}^{\infty} E(y_t y_{t+h}) = \frac{1}{2} \left[ \sum_{h=-\infty}^{\infty} E(y_t y_{t+h}) - E y_t^2 \right], \quad \hat{\Lambda}_{yy} = \frac{1}{2} \left[ \sum_{h=-n+1}^{n-1} k \left( \frac{h}{m} \right) \hat{\Gamma}_{yy}(h) - \hat{\Gamma}_{yy}(0) \right],$$

where $\hat{\Gamma}_{yy}(h)$ is the $(1,1)$th element of $\hat{\Gamma}(h)$, and then $\sqrt{n/m} (\hat{\Lambda}_{yy} - \Lambda_{yy}) \to_d N(0, \Phi_{11}/4)$.

However, deriving the asymptotics of the off-diagonal elements of $\hat{\Lambda}$ is not trivial, because $E(y_t \Delta x_{t+h}) \neq E(y_t \Delta x_{t-h})$ and hence the identity in (13) does generalize to the off-diagonal elements:

$$\Lambda_{y\Delta x} = \sum_{h=1}^{\infty} E(y_t \Delta x_{t+h}) \neq \frac{1}{2} \left[ \sum_{h=-\infty}^{\infty} E(y_t \Delta x_{t+h}) - E y_t \Delta x_t \right].$$

Therefore, we need to return to the original derivation. The limiting distributions of spectral density estimators have traditionally been analyzed using their representation in terms of periodograms (e.g. Hannan, 1970, Theorem 11):

$$\sum_{h=-n+1}^{n-1} k \left( \frac{h}{m} \right) \hat{\Gamma}(h) = \sum_{h=-n+1}^{n-1} k \left( \frac{h}{m} \right) \int_{-\pi}^{\pi} I_z(\omega) e^{i\omega h} d\omega$$

$$= \pi K_n(\omega) I_z(\omega) d\omega \approx \sum_{j=-n}^{n} K_n(\omega_j) I_z(\omega_j) \frac{2\pi}{n},$$

where $K_n(\omega) = \sum_{h=-n+1}^{n-1} k(h/m) e^{i\omega h}$ (frequency window) and $\omega_j = 2\pi j/n$. Under standard regularity conditions, $K_n(\omega)$ approaches a delta-function as $n \to \infty$, and since $I_z(\omega_j)$ are asymptotically independent, we obtain the asymptotic normality of $\sum_{h=-n+1}^{n-1} k(h/m) \hat{\Gamma}(h)$.

However, this approach does not work in the one-sided case when the summation of $\hat{\Gamma}(h)$ is taken only for positive $h$. Specifically,

$$\sum_{h=1}^{n-1} k \left( \frac{h}{m} \right) \hat{\Gamma}(h) = \sum_{h=1}^{n-1} k \left( \frac{h}{m} \right) \int_{-\pi}^{\pi} I_z(\omega) e^{i\omega h} d\omega$$

$$= \int_{-\pi}^{\pi} \tilde{K}_n(\omega) I_z(\omega) d\omega, \quad \tilde{K}_n(\omega) = \sum_{h=1}^{n-1} k \left( \frac{h}{m} \right) e^{i\omega h}.$$

Unlike $K_n(\omega)$, the one-sided $\tilde{K}_n(\omega)$ does not have a simple expression such as a Fejér kernel. In particular, it has a nonnegligible imaginary part, because it involves only positive $h$. The fact that there is no published result on the limiting distribution of $\hat{\Lambda}_{y\Delta x}$, despite its importance in econometrics, also suggests its difficulty.

In the present paper, we work directly with $\hat{\Gamma}_{y\Delta x}$ by applying the martingale approximation a la Phillips and Solo (1992) and show the asymptotic normality of $\hat{\lambda}_{y,\Delta x}$. The following theorem establishes it.
Theorem 2 If Assumptions A, K and M hold and $m^2/n + n/m^{2q+1} \to 0$, then
\[
\sqrt{\frac{n}{m}} \left( \hat{\lambda}_{y,\Delta x} - \lambda_{y,\Delta x} \right) \to_d N(0, V), \quad \text{as } n \to \infty.
\]

Unlike the regression-based tests, neither a non-zero intercept in $(y_t, x_t)$ nor a linear trend in $x_t$ affects the limiting distribution. Because $\Delta(x_t + \mu) = \Delta x_t$, $\hat{\lambda}_{y,\Delta x}$ is invariant to the presence of a non-zero intercept in $x_t$. For a non-zero intercept in $y_t$ and a linear trend in $x_t$, if we replace $(y_t, \Delta x_{t-h})$ with $(y_t - \bar{y}, \Delta x_{t-h} - \bar{\Delta x})$, where $\bar{y}$ and $\bar{\Delta x}$ denote the sample average of $y_t$ and $\Delta x_t$, then $\hat{\lambda}_{y,\Delta x}$ has the stated asymptotic distribution.\(^7\)

The optimal bandwidth $m^*$ in (12) does not satisfy the rate condition on $m$ of Theorem 2, which is a standard result when the bandwidth is chosen to minimize the mean squared error. $m$ needs to grow faster than $m^*$ for Theorem 2 to hold. Since the optimal rate of increase of $m$ is $n^{1/(2q+1)}$ from Remark 3, the upper bound on $m$, $m^2/n \to 0$, does not appear to pose a severe problem when $q$ is 1 or 2.

3.2 The limit distribution when $x_t$ is modelled as local to unity

Consider the case where $x_t$ is a local-to-unity process:

**Assumption B**

\[
x_t = (1 + c/n) x_{t-1} + u_t, \quad t = 1, 2, \ldots, n, \quad n = 1, 2, \ldots \quad c < 0,
\]

\[
x_t = 0 \quad \text{for } t \leq 0,
\]

\[
z_t^* = (y_t, u_t)' \text{ satisfies Assumption A.}
\]

Then $\lambda_{y,\Delta x} = \sum_{h=1}^{\infty} \text{cov}(y_t, u_{t-h}) + O(n^{-1})$ as seen in (8). The following Lemma establishes the first order equivalence of the limit theory for $\hat{\lambda}_{y,\Delta x}$ under both $I(1)$ and local to unity assumptions on $x_t$.

**Lemma 3** Suppose Assumptions B, K and M hold. Then $\hat{\lambda}_{y,\Delta x} = \sum_{h=1}^{n-1} k((h-1)/m)\hat{\Gamma}_{uy}(h) + O_p((m/n))$. If, in addition, $m^2/n + n/m^{2q+1} \to 0$, then $\sqrt{n/m}(\hat{\lambda}_{y,\Delta x} - \lambda_{y,\Delta x}) \to_d N(0, V)$, where $\hat{\Gamma}_{uy}(h)$ and $V$ are defined in (11) and Lemma 1, respectively, with $u_t$ replacing $\Delta x_t$.

The fact that the limiting distribution is the same for all finite $c \leq 0$ has important practical implications, since it means that no prior knowledge on $c$ is required in order to conduct inference in a local-to-unity model. By contrast, many econometric procedures, including several common cointegration tests, that are valid for $c = 0$ may fail for $c < 0$.

\(^7\)If $y_t$ is trend stationary, employing the detrended residual gives the same limiting distribution.
3.3 The limit distribution when $x_t$ is $I(0)$

The argument so far is based on the assumption that $x_t$ is $I(1)/local-to-unity. However, in practice often we do not have strong prior knowledge as to whether $x_t$ is $I(1)$ or $I(0). With an additional Lipschitz continuity assumption on the kernel, $\hat{\lambda}_{y,\Delta x}$ converges to $Ey_tx_{t-1} = \lambda_{y,\Delta x}$ when $x_t$ is an $I(0)$ process. Let us first state the assumptions on $x_t$ and $y_t$.

Assumption C

$$v_t = \begin{pmatrix} y_t \\ x_t \end{pmatrix} = B(L)\varepsilon_t = \sum_{j=0}^{\infty}B_j\varepsilon_{t-j}, \quad \sum_{j=0}^{\infty}j||B_j|| < \infty, \quad (14)$$

$$\varepsilon_t \sim \text{i.i.d. } (0, I_2), \quad \text{with finite fourth moment}$$

$$\sum_{-\infty}^{\infty}|h|^4||\gamma(h)|| < \infty, \quad \delta > 1; \quad \gamma(h) = \begin{bmatrix} \gamma_{yy}(h) & \gamma_{yx}(h) \\ \gamma_{yx}(h) & \gamma_{xx}(h) \end{bmatrix} = Ev_tv'_{t+h},$$

and $\tilde{f}_{xx}(0), \tilde{f}_{yy}(0) > 0$, where $\tilde{f}_{xx}(\lambda)$ and $\tilde{f}_{yy}(\lambda)$ are the spectral densities of $x_t$ and $y_t$.

We use $\gamma(h)$ to denote the autocovariance of $v_t$ in order to distinguish it from the autocovariance of $z_t$ in Assumption A. Note that $\lambda_{y,\Delta x} = Ey_tx_{t-1} = \gamma_{xy}(1)$.

Lemma 4 If Assumptions C, K and M hold and $k(x)$ is Lipschitz(1), then

$$\sqrt{n}\left(\hat{\lambda}_{y,\Delta x} - \lambda_{y,\Delta x}\right) = \sqrt{n}\left(\hat{\gamma}_{xy}(1) - \gamma_{xy}(1)\right) + B_n + o_p(1), \quad (15)$$

where $\hat{\gamma}_{xy}(1) = n^{-1}\sum_{t=2}^{n}y_tx_{t-1}$ and $B_n$ is the bias term satisfying

$$B_n = \begin{cases} 0, & \text{if } Ey_tx_{t-h} = 0 \text{ for all } h \geq 2, \\ O(n^{-1/2}m^{-q}), & \text{otherwise}. \end{cases}$$

In addition, $\sqrt{n}\left(\hat{\gamma}_{xy}(1) - \gamma_{xy}(1)\right) \to_d N(0, \Xi)$ as $n \to \infty$, where

$$\Xi = \sum_{u=-\infty}^{\infty} \left\{ \gamma_{xx}(u)\gamma_{yy}(u) + \gamma_{xy}(u+1)\gamma_{yx}(u-1) \right\} + \sum_{u=-\infty}^{\infty} k_{xyxy}(0, 1, u, u+1),$$

and $k_{xyxy}(0, a, b, c)$ is the fourth cumulant of $(x_t, y_{t+a}, x_{t+b}, y_{t+c})'$.

If one knew $x_t$ were $I(0)$, then one would estimate $Ey_tx_{t-1}$ by $\hat{\gamma}_{xy}(1)$, and the limiting variance of $\hat{\lambda}_{y,\Delta x}$ is the same as that of $\hat{\gamma}_{xy}(1)$. Therefore, $\hat{\lambda}_{y,\Delta x}$ is robust to misspecification of the order of integration, apart from the bias term in (15), which disappears when (1) holds.
4 Possible ways to conduct inference

4.1 Estimation of the limiting variance of the estimator

Suppose that $x_t$ is $I(1)$ and Theorem 2 gives the limiting distribution of $\hat{\lambda}_{y,\Delta x}$. In order to conduct inference, we need to estimate $V$. Of course, we can use $\hat{V} = 4\pi^2 \int_0^\infty k^2(x) dx \hat{f}_{yy}(0) \hat{f}_{\Delta x \Delta x}(0)$, where $\hat{f}_{ab}$ is a consistent periodogram-based estimator of $f_{ab}$.

We may also consider another estimator of $V$, $\tilde{V}$, whose particularly good performance is suggested by the simulations in Section 5. It is based on the exact finite sample variance of $\hat{\lambda}_{y,\Delta x}$, which is given by (see equations (34)-(36) in the proof of Lemma 1)

$$\frac{n}{m} \text{var} \left( \hat{\lambda}_{y,\Delta x} \right)$$

$$= \frac{1}{m} \sum_{h' = 1}^{n-1} \sum_{h = 1}^{n-1} k \left( \frac{h' - 1}{m} \right) k \left( \frac{h - 1}{m} \right) \sum_{u = -\infty}^{\infty} \{ \Gamma_{\Delta x \Delta x}(u) \Gamma_{yy}(u + h - h') + \Gamma_{\Delta x y}(u + h) \Gamma_{y\Delta x}(u - h') + k_{\Delta x y \Delta x y}(0, h', u, u + h) \} \phi_n(u, h', h),$$

where $\phi_n(u, h', h)$ is defined in the proof of Lemma 1. Since the terms involving $\Gamma_{\Delta x y}(\cdot)\Gamma_{y\Delta x}(\cdot)$ and the cumulants disappear in the limit and $\phi_n(u, h', h) = 1$ for the relevant values of $(u, h', h)$, define $V$ as:

$$\tilde{V} = \frac{1}{m} \sum_{h' = 1}^{n-1} \sum_{h = 1}^{n-1} k \left( \frac{h' - 1}{m} \right) k \left( \frac{h - 1}{m} \right)$$

$$\times \sum_{u = -\infty}^{\infty} \tilde{k} \left( \frac{u}{\tilde{m}} \right) \tilde{\Gamma}_{\Delta x \Delta x}(u) \tilde{k} \left( \frac{u + h - h'}{\tilde{m}} \right) \tilde{\Gamma}_{yy}(u + h - h'),$$

(16)

where $\tilde{k}(x)$ is a kernel and $\tilde{m}$ is a bandwidth. $k(x)$ and $m$ can, but do not need to, be the same as $k(x)$ and $m$.

Estimating $V$ by $\tilde{V}$ reduces the error from the approximation of the discrete sum in (32) by an integral and gives better finite sample performance than estimating $V$ by $\hat{V}$. (The results using $\tilde{V}$ are not reported in the present paper).

Suppose that $(y_t, \Delta x_t)$ satisfies Assumption A and hence $x_t$ is $I(1)$. Then, we may test hypotheses on $\lambda_{y,\Delta x}$ using a $t$-type statistic of the form

$$t_\lambda = \frac{\sqrt{\pi / m} \left( \hat{\lambda}_{y,\Delta x} - \lambda_{y,\Delta x} \right)}{\sqrt{\tilde{V}}},$$

(17)

However, $\tilde{V}_2$ did not perform as well as $\tilde{V}$ in simulations.
where $\hat{\lambda}_y, \Delta x$ and $\tilde{V}$ are defined in (11) and (16) respectively. Of course orthogonality (1) implies the null $\lambda_{y, \Delta x} = 0$.\(^9\) The following Lemma and its corollary show that $t_\lambda$ converges to a $N(0,1)$ random variable.

**Lemma 5** If Assumptions A or B and K and M hold, the kernel $\tilde{k}(x)$ satisfies Assumption K with $\tilde{q}$ replacing $q$, $\tilde{k}(x) = 0$ if $|x| > 1$, and $1/\hat{m} + \hat{m}\delta/n \rightarrow 0$, then $\tilde{V} \rightarrow_p V$ as $n \rightarrow \infty$.

**Corollary 6** If the assumptions of Theorem 2 or Lemma 3 and Lemma 5 hold, then $t_\lambda \rightarrow_d N(0,1)$ as $n \rightarrow \infty$.

### 4.2 Conservative inference when $x_t$ is $I(0)$

Consider the case in which $(y_t, x_t)$ follows (14) and thus $x_t$ is $I(0)$. It is easy to show that the test based on $t_\lambda$ remains consistent. Suppose that we test $H_0 : \lambda_{y, \Delta x} = E_y x_{t-1} = 0$ but $\lambda_{y, \Delta x} \neq 0$. Then we have, from Lemma 4,

$$t_\lambda = \frac{n^{1/2}\hat{\lambda}_{y, \Delta x}}{(V)^{1/2}\hat{m}^{1/2}} = \frac{n^{1/2}(\hat{\lambda}_{y, \Delta x} - \lambda_{y, \Delta x}) + n^{1/2}\lambda_{y, \Delta x}}{(V)^{1/2}\hat{m}^{1/2}} = \frac{n^{1/2}\lambda_{y, \Delta x}(1 + o_p(1))}{(V)^{1/2}\hat{m}^{1/2}}.$$

Since $\tilde{V} \rightarrow_p f_{\Delta x \Delta x}(0) = 0$ and $n^{1/2}\hat{m}^{-1/2} \rightarrow \infty$, it follows that $|t_\lambda| \rightarrow \infty$ as $n \rightarrow \infty$. Indeed, $t_\lambda$ diverges at a faster rate than $n^{1/2}\hat{m}^{-1/2}$, the rate of divergence in the $I(1)$ case.

Although Corollary 6 does not hold when $x_t$ is $I(0)$, we still have $t_\lambda \rightarrow_p 0$ when $\hat{m}$ and $\hat{k}(x)$ are chosen appropriately. It thus serves as a tool for conservative inference even when $x_t$ is $I(0)$. In particular, if the Bartlett kernel $\hat{k}(x) = (1 - |x|)1\{|x| \leq 1\}$ is used in $\tilde{V}$ in (16) and $E_y x_{t-h} = 0$ for all $h \geq 2$ (which holds under the null hypothesis of orthogonality), then $t_\lambda$ is $O_p((\hat{m}/m)^{1/2})$.

**Lemma 7** If Assumptions C, K and M hold, $\hat{k}(x)$ is the Bartlett kernel, $1/\hat{m} + \hat{m}/n \rightarrow 0$, and $E_y x_{t-h} = 0$ for all $h \geq 2$, then $t_\lambda = O_p((\hat{m}/m)^{1/2})$ as $n \rightarrow \infty$.

In order to understand the convergence, rewrite $t_\lambda$ as

$$t_\lambda = \frac{n^{1/2}(\hat{\lambda}_{y, \Delta x} - \lambda_{y, \Delta x})}{(V)^{1/2}\hat{m}^{1/2}}.$$

The numerator converges to a Gaussian random variable from Lemma 4. $\tilde{V}$ in the denominator is an estimate of $f_{\Delta x \Delta x}(0) = 0$ and hence converges to $0$ as $\hat{m} \rightarrow \infty$. Because $m$ tends to infinity, the asymptotic behavior of $t_\lambda$ depends on the rate of convergence of $\tilde{V}$. Letting $\hat{m}$ tend to infinity but not too quickly prevents $\tilde{V}$ from converging to $0$ too fast and makes $t_\lambda$ converge to $0$ in probability.

Therefore, by choosing $\hat{m}$ appropriately, the $t_\lambda$ statistic provides a conservative inferential tool that converges to $N(0,1)$ if $x_t$ is $I(1)$ or local to unity but converges to zero when $x_t$ is $I(0)$. Thus, the rejection rate will not exceed the nominal level. This is summarized in the following Lemma.

\(^9\)A detailed description of the implementation is given in Section 5.
Lemma 8 If either (i) Assumptions A or B and K and M hold, or (ii) Assumptions C, K and M hold with $Ey_{\tau t-h} = 0$ for all $h \geq 2$, and, in addition, $k(x)$ is Lipshitz(1), $\tilde{k}(x)$ is the Bartlett kernel, and $m^2/n + n/m^{2q+1} + 1/\tilde{m} + \tilde{m}/n + \tilde{m}/m \to 0$, then

$$\text{Pr}(|t_\lambda| \geq z_{1-\alpha/2}) \to \alpha' \leq \alpha \text{ as } n \to \infty, \text{ where } z_{1-\alpha/2} \text{ is the } 100(1-\alpha/2) \text{ percentile of the } N(0,1) \text{ distribution.}$$

4.3 Power against nonstationary regression alternatives

Based on the empirical observation that the dependent variables in predictive tests (e.g. returns) typically appear stationary, we have so far focused on the models where $y_t$ is assumed to be $I(0)$. As discussed in Section 2, for fixed values of $\beta_1$, this rules out regression-type alternatives where $x_t$ is $I(1)$ and $y_t$ is linearly related to $x_{t-1}$ as in (3). However, under local alternatives for which $\beta_1$ is of order $n^{-1/2}$ or smaller, the variance of the nonstationary component $\beta_1 x_{t-1}$ no longer dominates that of the stationary residual. Thus such local alternatives are potentially consistent with the observation that $y_t$ appears essentially stationary in its behavior.

Thus we next examine the power of our covariance-based test against the following regression alternative, which includes both fixed and local alternatives.

Assumption D

$(y_t, x_t)$ is generated by

$y_t = \beta_n x_{t-1} + u_t,$

where $(u_t, \Delta x_t)'$ is generated by a linear process $A(L)\varepsilon_t$ that satisfy Assumption A and $x_0 = O_p(1)$. $\Gamma_{uu}(h), \Gamma_{u\Delta x}(h), \Gamma_{\Delta x u}(h)$, and $\Gamma_{\Delta x \Delta x}(h)$ are defined analogously to Assumption A and they satisfy the summability condition in Assumption A.

We exclude the constant term in order to simplify the discussion. Under Assumption D, we have $\text{cov}(y_t, x_{t-1}) = \beta_n \text{var}(x_{t-1}) + \text{cov}(u_t, x_{t-1})$, which is not equal to zero in general. Indeed, if $1/\beta_n = o(n)$ then $\text{cov}(y_t, x_{t-1})$ diverges at the rate $n\beta_n$. The following lemma summarizes the behavior of $\lambda_{y, \Delta x}$ and $\tilde{V}$.

Lemma 9 If Assumptions D, K, and M hold, $\lambda_{u, \Delta x} = 0$ and $m^2/n \to 0$, then

(a) $\lambda_{y, \Delta x} = m\beta_n \left[ (1/2) \left( B^2(1) + 2\pi f_{\Delta x \Delta x}(0) \right) \right] \int_0^1 k(x) dx \left( 1 + o_p(1) \right).$

If, in addition, $\tilde{m}^2/n \to 0$ and $n\beta_n \to \infty$, then

(b) $\tilde{V} = \left\{ \left( \beta_n^2 n\tilde{m} \int_0^1 \tilde{k}(x) dx \int_0^1 B^2(r) dr \left( 1 + o_p(1) \right) \right) + 2\pi f_{uu}(0) \right\}$

$\times 2\pi f_{\Delta x \Delta x}(0) \int_0^\infty k^2(x) dx \left( 1 + o_p(1) \right).$
\( \hat{\lambda}_{y,\Delta x} \) converges to a non-degenerate limit if \( m\beta_n \) is bounded away from 0. The behavior of \( \tilde{V} \) is dominated either by the term with \( \beta_n^2 n\tilde{m} \) or \( 2\pi f_{uu}(0) \). Assume \( \tilde{m}/m \to 0 \) as assumed in Lemma 8, and let \( \xi_n \) denote a generic random variable that has a non-degenerate limiting distribution. If \( \beta_n^2 n\tilde{m} \to \infty \), then \( \tilde{V} \) diverges and \( t_\lambda = (n/m)^{1/2} \hat{\lambda}_{y,\Delta x}(\tilde{V})^{-1/2} = (m/\tilde{m})^{1/2} \xi_n \), which diverges to infinity. If \( \beta_n \) tends to 0 faster and \( \beta_n^2 n\tilde{m} \to 0 \), then \( \tilde{V} \) is \( O_p(1) \) and \( t_\lambda = \beta_n n^{1/2} m^{1/2} \xi_n \).

Consequently, the covariance-based test has a nonnegligible power against local alternatives of the form \( \beta_n \sim b n^{-1/2} m^{-1/2} \) with \( b \neq 0 \). Since regression-based tests have power against alternatives for which \( \beta_n \sim b n^{-1} \), the covariance-based test loses power relative to regression-based tests by the order of \( (n/m)^{1/2} \) as the price of its greater flexibility. This reflects the fact that \( t_\lambda \) uses \( m \) sample autocovariances whereas regression-based tests use effectively \( n \) sample autocovariances. Despite the loss of power, the \( t_\lambda \)-test is still consistent against the alternatives with \( \beta_n \sim b n^{-1/2} m^{-c} \) for \( c \in (0, 1/2) \), in which the variance of the \( I(1) \) component is dominated by the variance of the residual \( u_t \) and \( y_t \) may appear to be \( I(0) \). This result is summarized in the following Corollary, which follows immediately from Lemma 9.

**Corollary 10** If the assumptions of Lemma 9 hold and \( \tilde{m}/m \to 0 \), then the test statistic \( t_\lambda \) for the test of \( H_0: \hat{\lambda}_{y,\Delta x} = 0 \) has a nonnegligible power against alternatives in Assumption D of the form \( \beta_n = b (nm)^{-1/2} \) with \( b \neq 0 \) and diverges against alternatives of the form \( \beta_n = b n^{-1/2} m^{-c} \) for \( c \in (0, 1/2) \).

### 5 Finite sample performance: simulation results

This section provides a modest simulation study to gauge the small sample accuracy of the proposed test. The results indicate reasonable (and often quite good) size and power in sample sizes as small as 100.

For the simulations below we have in mind a test of \( y_t \) orthogonal to \( I_{x,t-1} \), the information contained in past \( x_t \), as in (1). This is often tested in practice using a regression of \( y_t \) on \( x_{t-1} \) as in (3). Since size distortions rule out standard regression only for \( x_t \) highly serially correlated, it is this case that we focus on. In particular, we consider both first and second order autoregressive models for \( x_t \):

\[
x_t = \rho_0 + \rho_1 x_{t-1} + u_{2t}, \quad \text{AR(1)}
\]

\[
x_t = \rho_0 + \rho_1 x_{t-1} + \rho_2 x_{t-2} + u_{2t}, \quad \text{AR(2)}
\]

The AR(1) model may also be written as a unit root/local to unity process by letting

\[
\rho_1 = 1 + c/n, \quad c \leq 0.
\]

Usually the primary economic interest centers on the relation between \( y_t \) and \( x_{t-1} \). Under the null hypothesis \( y_t \) is orthogonal to \( I_{x,t-1} \) and often an efficient market condition will also imply that \( y_t \) is orthogonal to its own past. In the simulations, the process for \( y_t \) under the null hypothesis is therefore specified by

\[
y_t = d_t + u_{1t},
\]

17
where the innovation $u_{1t}$ is discussed below and the deterministic component $d_t$ consists of either an intercept or a trend:

$$d_t = \delta_0 \text{ or } d_t = \delta_0 + \delta_1 t. \quad (22)$$

We employ two different specifications for $y_t$ under the alternative hypothesis when investigating finite sample power. First we consider the standard regression specification

$$y_t = d_t + \beta x_{t-1} + u_{1t}. \quad (24)$$

In the unit root/local to unity context, (24) implies that $y_t$ and $x_t$ contain an equally persistent component and are cointegrated when $\beta \neq 0$. While (24) has traditionally been the alternative on which the literature has focused, in certain applications it may be overly restrictive. For example, as discussed in the introduction, it is not clear that one would want to model (near) unit root components in stock or exchange rate returns on theoretical grounds, and empirically they show little serial correlation. Thus, it also seems reasonable to consider test performance under alternatives that allow $y_t$ to remain stationary even when $x_t$ is highly persistent. A simple alternative of this type is given by a regression of $y_t$ on quasi-differenced $x_t$ as in

$$y_t = d_t + \gamma \left(1 - \left(1 + \frac{c}{n}\right) L\right) x_{t-1} + u_{1t}, \quad (25)$$

where $x_t$ is given by the AR(1) specification in (18). While both sides of (25) are stationary, the data generating process permits $y_t$ and $x_t$ to have different orders of integration. This may be rewritten as

$$y_t = d_t + \gamma u_{2,t-1} + u_{1t}, \quad (26)$$

in which form it also makes sense for more general models of $x_t$.

Finally, since the orthogonality between $y_t$ and past $x_t$ (i.e. $x_{t-j}$, $j \geq 1$) does not rule out contemporaneous covariance between $y_t$ and $x_t$, we allow the two innovation processes to be correlated under both the null and alternative. They are specified by

$$u = \begin{pmatrix} u_{1t} & u_{2t} \end{pmatrix} = \Sigma^{1/2} \varepsilon_t, \quad \varepsilon_t \sim \text{i.i.d. } N(0, I_2)$$

$$\Sigma = \Sigma^{1/2}(\Sigma^{1/2})' = \begin{pmatrix} 1 & \sigma_{12} \\ \sigma_{12} & 1 \end{pmatrix}. \quad (27)$$

Our primary interest lies in the performance of the covariance-based statistic $t_\lambda$ given in (17), which was estimated as follows. In the trend model (23), we first demeaned $\Delta x_t$ (thereby removing the trend in $x_t$) and detrended $y_t$ prior to estimation. In the intercept model (22) only $y_t$ was demeaned. Using this detrended (or demeaned) data we then estimated the limiting covariance $\lambda_{y,\Delta x}$ defined in (6) using the standard kernel covariance estimator $\hat{\lambda}_{y,\Delta x}$ given in (11). Likewise, we estimated its asymptotic variance $V$ (see Lemma 1) using the kernel estimator $\tilde{V}$ following (16).

Both kernel estimation procedures require the choice of kernel and bandwidth. The theoretical results allow considerable flexibility in the choice of the kernel $k(x)$.
in the estimation of $\lambda_{y,\Delta x}$. However, to ensure conservative inference for stationary $x_t$, Lemma 7 mandates use of the Bartlett kernel for $\hat{k}(x)$ in the estimation of $V$. We therefore used the Bartlett kernel for both estimators.\footnote{Alternate choices for $k(x)$ are explored in Section 5.3.} The bandwidth parameter $m$ in the estimation of $\lambda_{y,\Delta x}$ is selected using the optimal bandwidth formula given in (12). Implementation of this formula in practice requires the use of a first-stage parametric approximation model. As in Andrews (1991), this is assumed only to provide a parsimonious approximation, not a correct specification. Although separate univariate AR(1) models are typically employed, the optimal bandwidth in this case depends on the behavior of the cross auto-correlations and necessitates a joint model. Including a moving average component also seems desirable given possible over-differencing in $\Delta x_t$. Therefore we estimated the first-stage VARMA(1,1) model $z_t = \tilde{A}z_{t-1} + \tilde{\varepsilon}_t + B\varepsilon_{t-1}$ for $z = (y_t, \Delta x_t)'$ employing the three-stage linear regression method of Dufour and Pelletier (2002) and then used the estimated parameters to calculate $m^*$ in (12).\footnote{In this model, $f(0) = \frac{1}{2\pi} (\Delta + \Delta' - \Gamma(0))$ where $\Delta = \Gamma(0)[I_2 - A]'^{-1}$ and $\text{vec}(\Gamma(0)) = [I_2 - (A \otimes A)]^{-1}\text{vec}(ASB' + \Sigma + B\Sigma A' + B\Sigma B')$, and the term $\sum_{h=1}^{\infty} \Gamma_{\Delta x \Delta x}(h)h^9$ is given by the (2,1)th element of $(2\pi)^{-1}\Gamma(1)(I_2 - A')^{-2}$, where $\Gamma(1) = \Gamma(0)A' + B\Sigma B'$. We impose some constraints on the ARMA parameters to insure stationarity and invertibility and also impose $n^{0.9}$ as an upper bound on $m$.} The choice of the second bandwidth parameter $\tilde{m}$ used in the estimation of $V$ is constrained by Lemma 7, which requires $\tilde{m} = o(m)$. While clearly arbitrary, our choice of $\tilde{m} = m^{0.9}$ appeared sufficient to insure conservative inference in the stationary case, with minimal cost in overall performance.

As a basis of comparison we also provide some simulation results for both the standard regression $t$-test and the size-adjusted regression-based approach, using the two stage Bonferroni-bounds test of Cavanagh et al. (1995) (hereafter CES).\footnote{We thank James Stock for use of his Gauss code. Following CES, we impose a finite sample size-adjustment, without which the test would be quite conservative. The reader is referred to CES for the details.} These tests are developed under the assumption that $y_t$ is a martingale difference sequence (MDS) under the null, which is commonly imposed in the finance literature when one period returns are used. Our test was developed in a more general setting, allowing for serial correlation in $y_t$, and thus our use of $V$ as defined in Lemma 1b and estimated by $\hat{V}$ in (16) is analogous to the use of robust standard errors in regression. This generality can be quite useful, particularly when employing long-horizon returns for which the MDS assumption is necessarily violated and when analyzing test power, since the MDS assumption cannot be imposed under the alternative hypothesis. On the other hand, when the MDS assumption is appropriate it may come at some cost in terms of power. In order to allow for a clear comparison to predictive regression methods which do not employ HAC standard error estimates, we simplify $V$ by imposing the MDS assumption on $y_t$ unless stated otherwise. Specifically, $\Gamma_{yy}(h)$ and $\hat{\Gamma}_{yy}(h)$ with $|h| > 0$ in $V$ and $\hat{V}$ are replaced by 0, giving $V_{MDS} \equiv 2\pi^2 \Gamma_{yy}(0)f_{\Delta x \Delta x}(0)\int_{0}^{\infty} k^2(x)dx$ and

$$\hat{V}_{MDS} = \frac{1}{m} \sum_{h'=1}^{n-1} \sum_{h=1}^{n-1} k\left(\frac{h'-1}{m}\right)k\left(\frac{h-1}{m}\right)\hat{k}\left(\frac{h'-h}{\tilde{m}}\right)\hat{\Gamma}_{\Delta x \Delta x}(h'-h)\hat{\Gamma}_{yy}(0).$$
In order to preserve space we report only the results with $\tilde{V}_{MDS}$. The full set of results using the more general $\tilde{V}$ given by (16) are available upon request. The size of the tests are quite similar in both cases. As expected, although the overall pattern is similar, the power is generally better when the MDS assumption is imposed. All results below are based on 2000 replications, with results reported for sample sizes of $n = 100$ and 200.

5.1 Size

We first simulate under the null hypothesis with $y_t$ given by (21) and $x_t$ given by the AR(1) process (18) with $\rho_1$ modelled local-to-unity as in (20). Results are provided for various values of both $c$ (and therefore $\rho_1$) and $\sigma_{12}$. In order to set a basis of comparison, Table 1 shows empirical rejection rates for the standard two-sided regression t-test ($y_t$ regressed on $x_{t-1}$) with a nominal level of 5 percent. The rejection rates are reasonable for small values of $\rho_1$ and/or $\sigma_{12}$ but grow highly unreliable as $\rho_1$ approaches one and the residual correlation increases. The size problem is particularly severe in the model with trend, for which rejection rates can exceed 50 percent.

By contrast, the covariance-based test $t_\lambda$, whose rejection rates are shown in Table 2, is quite reliable in sample sizes as small as one hundred across the whole range of parameter values in the both the intercept and trend models. The test can become slightly conservative, particularly for large (negative) values of $c$. This is consistent with Lemma 8. However, the empirical rejection rates remain within a few percentage points of the nominal value. This good performance corroborates the theoretical results. Of course, good performance may also be obtained by properly size adjusting the regression-based tests, as in the bounds tests of CES (see their Table 4).

Following the empirical literature, we also consider longer-horizon returns. We may no longer impose an MDS assumption when estimating $V$, but otherwise require no explicit corrections to handle the moving average components induced by the overlapping returns; for fixed horizon ($k$) we simply have to define

$$y_{t,k} = (y_t + y_{t-1} + \ldots + y_{t-k+1}) = \phi(L)y_t \quad \text{and} \quad \Delta x_{t,k} = \Delta x_{t-k+1} = L^{(k-1)}\Delta x_t (28)$$

and apply the theoretical results to $(y_{t,k}, \Delta x_{t,k}) = \text{diag}(\phi(L), L^{k-1})A(L)\epsilon_t = A^*(L)\epsilon_t$. In finite sample, the accuracy of long-horizon tests typically depends on the ratio $k/n$. In Table 3, we match this ratio to the sample size ($n = 924$) and longest horizon (2 years, $k = 24$) used in the empirical application, yielding $k = 3$ for $n = 100$. This

$^{13}$Results (available upon request) using a 10% nominal level also confirm the the good properties of the covariance-based test discussed below. Note that Hodrick or HAC standard errors are unnecessary here since $u_t$ is taken to be i.i.d.

$^{14}$In estimation of $V$, the MDS assumption in no longer tenable since $y_{t,k}$ follows an $MA(k)$ if $y_t$ is an MDS. Thus in (16) we impose only that $\text{cov}(y_{t,k}, y_{t-h,k}) = 0$ for $h > k - 1$. To choose $m^*$ we estimate the same VARMA(1,1) described above using $z = (y_t, \Delta x_t)'$ and adjust the formula in (12) to account for the long-horizon returns. Specifically, we replace $f_{yy}(0)$ by $k^2f_{yy}(0)$ and $(2\pi)^{-1}\Gamma(1)(I_2 - A')^{-2}$ by $(2\pi)^{-1}\Gamma(1)(I - (A')^k)(I - A')^{-2}$ in footnote 11.
again yields reasonable size performance. Holding \( n = 100 \) fixed, but increasing the horizon to \( k = 5 \) leads to only a slight deterioration.

The model above is the baseline model most often used to evaluate size distortions in this context. However, our test is designed to work in a more general setting and it is also of interest to investigate finite sample performance under higher order autoregressive specifications for \( x_t \), such as the AR(2) model (19), with roots on or close to the unit circle. Rudebusch (1992, Table 2) finds that an AR(2) with \( \rho_1 + \rho_2 \) slightly below unity (with \( \rho_1 > 1 \) and \( \rho_2 < 0 \)) provides a good fit for a number of macroeconomic and financial time series. In order to roughly match these estimates we set

\[
\rho_1 = 1.5 \quad \text{and} \quad \rho_2 = -0.5 + c/n
\]

for the same values of \( c \) considered above. Thus, as in the AR(1) model, \( x_t \) is unit-root nonstationary for \( c = 0 \) (\( \rho_2 = -0.5 \)) and near-nonstationary for \( c < 0 \) (\( \rho_2 < -0.5 \)). The rejection rates for the covariance-based tests are shown in Table 4. The results remain fairly accurate even for \( n = 100 \), particularly in the demeaned case. By contrast, finite sample rejection rates for least squares (available upon request) reach to above 50% and do not improve with sample size for fixed \( c \).

In summary the size of the proposed covariance-based test seems generally to be reasonable, and is often quite accurate, even in sample sizes as small as \( n = 100 \). We next consider finite sample power.

### 5.2 Power

We first consider the power of the covariance-based test \( t_\lambda \) against the standard regression alternative given in (24) with \( \beta \neq 0 \) and local to unity \( x_t \) given by (18) and (20).\(^\text{15}\) For \( c = 0 \) this alternative constitutes a cointegrating relation, while for \( c << 0 \) the alternative is a stationary regression. The results are shown in Table 5. To save space we show only the demeaned case. As expected, the power of the test is reasonable, increasing in both sample size and distance from the null.

One of the goals of the covariance-based test was to simultaneously maintain power against alternatives which allow \( y_t \) (e.g. returns) to be stationary, despite near or even exact unit root behavior in \( x_t \). This avoids, for example, the implication that stock prices or exchange rates contain a (near) \( I(2) \) component under the alternative hypothesis when predictor variables are persistent. The data generating process in (25), together with (18), therefore provides a natural alternative in which to consider finite sample power in that it holds \( y_t \) stationary (but not over-differenced) regardless of the persistence in \( x_t \). In doing so, it incorporates both (3) and (9) as special cases for \( \rho_1 = 0 \) and \( \rho_1 = 1 \) respectively.

Finite sample power results for the covariance-based tests under the alternative in (25) with \( x_t \) given by (18) and (20) are shown in Table 6. The test is calculated in the same way as before, again using \( y_t \) and \( x_{t-1} \) as inputs. These rejection rates appear quite reasonable, again increasing in both sample size and distance from the null hypothesis.

\(^\text{15}\)We do not report size adjusted power, since both tests considered in this section have good size.
Many existing tests are based on a size adjusted regression of the type shown in (3). These procedures may be expected to have good power against regression alternatives when \( x_t \) is stationary (e.g. \( \rho_1 << 1 \) in (18) and \( \beta \neq 0 \) in (24)) and against cointegration or near-cointegration alternatives when \( x_t \) is near \( I(1) \) (e.g. \( \rho_1 \approx 1 \) in (18) and \( \beta \neq 0 \) in (24)). This is confirmed in Table 7, which shows finite sample power for the CES Bonferroni test procedure against \( \beta \neq 0 \) in (24) with local to unity \( x_t \) given by (18) and (20). As expected, the test exhibits very good power against this alternative and is in this case more powerful than \( t_\lambda \).

On the other hand, it is not clear that regression tests based on (3) should have much power against alternatives in which \( y_t \) and \( x_{t-1} \) exhibit different orders of integration. Table 8 provides rejection rates for the CES Bonferroni test against the same DGP used to assess the power of \( t_\lambda \) in Table 6, i.e. equations (18), (20), and (25). Confirming the reasoning above, the regression-based test does quite well for the larger values of \( c \) when \( x_t \) and \( y_t \) behave in a stationary manner, but performance deteriorates rapidly as \( x_t \) approaches nonstationarity (small \( c \)) and the alternative becomes unbalanced. Moreover, for small \( c \) the power does not seem to improve as we move further into the alternative. Nor, for fixed values of \( c \), do rejection rates increase much as the sample size increases. For example, in the worst case for \( c = 0 \) and \( \sigma_{12} = 0.95 \) (panel 2, row 2, last column), the power remains under 5 percent even for a population \( R^2 \) of 0.20 and a sample size of two-hundred. In fact, in results not shown, it remains under 10 percent for an \( R^2 \) of 0.50.

These simulations suggest that the covariance-based orthogonality test may provide power against a wider range of alternatives than do existing size-adjusted regression-based tests. In particular, they appear to provide reasonable power against both standard regression and unbalanced (i.e. \( y_t \sim I(0), \ x_{t-1} \sim I(1) \)) alternatives, whereas regression-based tests do particularly well against the alternatives for which they were designed, but provide little reliable power against unbalanced alternatives. This added generality does of course come at some cost in terms of power against certain specific alternatives and, in this sense, the two testing approaches (regression and covariance-based) are properly seen as compliments rather than substitutes.

### 5.3 Kernel Comparison

In the preceding simulations we employed the Bartlett (Newey-West) kernel for both \( k(x) \) and \( \tilde{k}(x) \). In the case of \( k \) this is needed to satisfy the conditions of Lemma 7. However, other kernel choices may be considered for \( k \). We therefore replicated Tables 2, 5, and 6 using three alternative kernels, the Parzen, Quadratic Spectral, and Tukey-Hanning kernels, defined respectively by

\[
k(x) = (1 - 6x^2 + 6|x|^3) \mathbb{I}(|x| < 1/2) + 2(1 - |x|)^3 \mathbb{I}(1/2 \leq |x| \leq 1), \quad k(x) = 25/(12\pi^2x^2) (\sin(6\pi x/5) - \cos(6\pi x/5)), \text{ and } k(x) = 1/2(1 + \cos \pi x) \mathbb{I}(|x| \leq 1).
\]

Although the performance of the test varied slightly according to the choice of kernel, the differences did not seem large enough to be important in practice. In addition, the relative ordering of the test across kernel choices varied with the choice of the specification of the data generating process.

Table 9 provides a representative comparison across three of these four kernels, the
Bartlett (NW), Parzen (PZ), and Quadratic Spectral (QS). The first two columns provide the values of $c$ and $\sigma_{12}$ respectively, the third column denotes the choice of kernel, the fourth column provides rejection rates under the null hypothesis, and the remaining columns provide rejection rates under the alternative. In the top panel the alternative is specified in levels as in Table 5, whereas in the bottom panel the alternative is rebalanced as in Table 6. As is apparent from the table, use of the Parzen kernel delivers modest power improvements against the levels alternative, whereas, depending on the parameters of the DGP, either the Bartlett (NW) or the Quadratic Spectral (QS) kernel tends to perform best against the rebalanced alternative.

6 Application to tests of stock return predictability

We use the method developed above to test the orthogonality of stock returns to the information in past short-term interest rates and dividend yields. Under the market efficiency/constant risk premium hypothesis it should not be possible to systematically forecast stock returns. Early tests of this hypothesis found fairly substantial predictability and thus had a large impact on the finance literature (see Campbell and Shiller (1988a,b), Fama and French (1988), Hodrick (1992), Shiller (1984)).

Although theoretical considerations may rule out exact unit root behavior in dividend yields and interest rates, near unit roots in the local to unity sense cannot be ruled out a priori. Empirically, both series are highly persistent, with confidence intervals on the largest root often containing one (Torous et al. (2005)). Moreover, although pre-determined, there is no reason to believe that these regressors are fully exogenous. For example, the stock price enters both the return and dividend yield. The combination of near unit root behavior and a failure of strict exogeneity is a recipe for size problems (Cavanagh et al. (1995)). Consequently, subsequent doubts have been raised regarding the evidence for predictability on account of the strong persistence in the regressors (Stambaugh (1986 & 1999) and Mankiw and Shapiro (1986)). This has spurred a large literature in an attempt to address this issue, and the degree to which evidence of predictability has been overstated remains a subject of ongoing debate.

Thus the literature to date has focused primarily on the issue of size distortion. However, near unit root regressors may also raise specification issues under the alternative, in the sense that a stationary variable, such as a stock return should not be linearly predictable by a unit (or near unit) root regressor (Lanne (2002)). Even if $y_t$
is $I(0)$ and $x_t$ is $I(1)$, $y_t$ may still be predictable based on the past history of $x_t$, as exemplified by (9) with $\gamma_1 \neq 0$. Yet, as the simulations underscored, regression tests based on (3) have unreliable power against such alternatives, even if size-adjusted. Therefore, while evidence of predictability may be overstated due to size distortion, it is also possible that it has been understated due to near unit root specification issues. Since the covariance-based tests address both issues simultaneously they may be useful in untangling these two effects.

We use monthly returns from 1927 to 2003. Following Campbell et al. (1997, chapter 7), we also consider separately the 1927-1951 and 1952-1994 subsamples, along with the more recent 1952-2003 subperiod. Monthly log returns are calculated as $r_{t+1} = \ln \left( \frac{P_{t+1} + D_{t+1}}{P_t} \right)$, where $P_t$ and $D_t$ are the stock price and dividend from the CRSP value-weighed index of NYSE, AMEX, and NASDAQ stocks. Real returns are formed by deflating nominal returns by the CPI. The dividend-price ratio is calculated in the standard way as the sum of dividends paid over the past twelve months, divided by the current level of the index: $d_t - p_t = \ln \left( \frac{D_t + \ldots + D_{t-11}}{P_t} \right)$. We denote the one-month treasury bill rate by $i_t$. Following the literature, we also consider longer-horizon returns of the form $r_{t+1} + \ldots + r_{t+k}$ for $k = 1, 3, 12,$ and $24$. HAC standard errors are employed for $k > 1$ in the regression analysis. Likewise, for the covariance-based test, the MDS assumption on $y_t$ is relaxed in the estimation of $V$, as detailed in footnote 14. For fixed $k$ our test requires no further correction or adjustment, as discussed in the simulation section above.

The first three rows in each panel of Table 10 show the standard regression coefficients, $R^2$s, and $t$-statistics. We defer discussion of the fourth row until later. The interest rate regressions show modest evidence of predictability whereas evidence using dividend yields is generally quite strong. Intuition for the potential bias and size distortion in these regressions is provided by Lewellen (2004) who expresses the bias in $\hat{\beta}$ in (3) in terms of the bias in $\hat{\rho}$ in (18) and the residual covariance $\sigma_{12}$ in (27):

$$E \left[ \hat{\beta} - \beta \right] = \frac{\sigma_{12}}{\sigma_{22}} E \left[ \hat{\rho} - \rho \right]. \quad (30)$$

The two ingredients needed to produce bias are thus persistent regressors and residual serial correlation. Table 11 shows the Stock (1991) confidence interval on the largest root in $x_t$ together with the estimated residual correlation $\delta = \text{corr}(\varepsilon_{1t}, \varepsilon_{2t})$. The two series both show large roots, with confidence intervals on the largest root containing one, but display quite different residual correlation properties. Estimates of $\delta$ are small for the interest rate series, suggesting only modest size distortion, but are close to negative one for the dividend price ratio. Intuitively, an increase in the current stock price corresponds to a higher return but lower dividend yield. Since the AR(1) coefficient estimate $\hat{\rho}_1$ is downward biased (Hurwitz (1950)), negative residual correlation implies positive bias in $\hat{\beta}$ (see (30)). In other words, the bias runs in the same direction as the observed alternative, leaving the results difficult to interpret.

---

20We thank John Campbell for kindly providing us with the original data for this project, which was later updated from CRSP.

21Similar results were also found replacing real by excess returns.
This preliminary analysis suggests that size distortion may be a more serious concern in the case of the dividend price ratio than it is for the interest rate regressions. This conjecture is supported by the results in Table 12. The table shows the covariance-based test statistic \( t_\lambda \), for which standard normal critical values apply, the two-sided p-value, and the optimal bandwidth \( m^* \), calculated in the same way as in the simulations (see Section 5 for details).\(^{22}\)

For the interest rate, the covariance-based tests in Table 12 provide overall evidence of predictability similar to that found from the standard regression tests of Table 10. In both cases, evidence of predictability is confined to the later sample periods (1952-1994 & 1952-2003). However, the strongest evidence from the covariance test come at medium horizons (3-12), whereas regression t-tests are largest at short horizons (1-3), showing little evidence of predictability at the 12 month horizon. On the other hand, in the case of the dividend price ratio, the covariance-based tests show far weaker evidence of predictability than do the standard regression-based tests. This agrees with the conclusion in several (but not all) previous studies that address the issue of size distortion in (3).\(^{23}\)

It may also be instructive to compare the empirical results from the standard regression and covariance based tests to those from a properly size adjusted regression test, such as the CES tests discussed in the section above. Since the CES tests apply only at short-horizons (k=1), we employ instead a similar bounds test proposed by Valkanov (2003) for use in the long horizon context. The last row of each panel of Table 10 shows the p-value from the Valkanov (2003) sup-bound tests. These p-values confirm the modest evidence of predictability found from the interest rate regressions. This is expected in light of the small residual cross correlations in Table 11, which suggest only modest distortion in standard tests. On the other hand, evidence of predictability in the dividend yield regression, for which residual cross-correlations are large, disappears in all but one of four samples, the 1952-1994 sub-period.

Thus with a few exceptions, the covariance and size-adjusted regression tests tell similar stories regarding predictability. Both tests confirm the modest evidence of interest rate predictability found from standard regressions, with the covariance test finding evidence at medium to longer horizons. Similarly both tests suggest show substantially less evidence of predictability than implied by standard, but possibly size-distorted regression tests.

7 Conclusion

In regression-based orthogonality tests it is often the case that the regressor is highly serially correlated, with an autoregressive root close or possibly equal to unity. This

\(^{22}\)We also employed fixed bandwidths of \( m = 1, 2, 5, \) and 10 (results available upon request). This produced similar qualitative results, but with larger values of \( m \) further increasing evidence of predictability using \( i_t \) and changing the sign of some insignificant statistics using \( d_t - p_t \). The demeaned version of the estimator was employed. Similar results (available upon request) were obtained using the detrended version.

is well known to cause size problems in standard tests. Simple two-stage procedures employing unit root tests together with size correction can generally correct this problem in the $I(1)$ case, but still produce size distortions under local-to-unity assumptions.

Roots near unity may also artificially restrict the allowable alternative hypothesis, leading to poor size-adjusted power under certain reasonable alternatives. For example, when the regressor has a unit root but the dependent variable does not, no linear relation between the two can exist, so that the true regression coefficient is forcibly equal to zero. A properly adjusted $t$-test based on this regression coefficient should therefore generally support the null of orthogonality. However, such a regression imbalance (i.e. $y_t \sim I(0), \ x_t \sim I(1)$) would not rule out a violation of orthogonality due to a linear relationship between the dependent variable and stationary transformations of the regressor.

The covariance-based test proposed here produces good size and power against alternatives in which the dependent variable (e.g. stock returns) is stationary, regardless of whether the predictor is stationary, nonstationary, or local to unity. This comes without resort to unit root pre-tests or other forms of prior information. Furthermore, because nonstandard distributions are avoided, size adjustments are unnecessary. Simulation results suggest reasonably good size and power in samples as small as one hundred, making this a practical tool for use in empirical applications.

Finally, we note that the formulation of the limiting covariance defined in (6) could be usefully modified in various ways in order to provide alternate orthogonality tests that also remain appropriate when $x_t$ and $y_t$ potentially exhibit different orders of integration. For example, one might consider a test based on the restriction that $\sum_{h=1}^{\infty} |\text{cov} (y_t, \Delta x_{t-h})| = 0.$ \footnote{We thank an anonymous referee for this valuable observation.} This departs from the standard covariance restriction in (2) that we generalize here, yet provides a stronger implication of (1) and thus could potentially be a promising avenue for future research. From a theoretical perspective, such an extension would be interesting and non-trivial, since deriving the joint properties of the absolute values of the sample covariances $|n^{-1} \sum_{t=h+1}^{n} y_t \Delta x_{t-h}|$ would be complicated considerably by the presence of the absolute value sign.

8 Appendix A: Proofs

In the following sections, $C$ denotes a generic constant such that $C \in (0, \infty)$ unless specified otherwise, and it may take different values in different places.

8.1 Proof of (8)

From the definition of $x_t$, we have

$$\Delta x_t = u_t + \frac{c}{n} x_{t-1} = \begin{cases} u_t + \frac{c}{n} \sum_{k=0}^{t-2} (1 + c/n)^k u_{t-1-k}, & t \geq 1, \\ 0, & t \leq 0, \end{cases}$$

(31)
with \( \sum_{k=0}^{t-1} = 0 \). It follows that \( \text{cov}(y_t, \Delta x_{t-h}) = \text{cov}(y_t, u_{t-h}) + \frac{c}{n} \sum_{k=0}^{t-h-2} (1 + c/n)^k \text{cov}(y_t, u_{t-h-1-k}) \) for \( t \geq h + 1 \), and 0 for \( t \leq h \). Therefore,

\[
\lambda_{y, \Delta x} = \lim_{t \to \infty} \sum_{h=1}^{t-1} \text{cov}(y_t, \Delta x_{t-h}) = \lim_{t \to \infty} \sum_{h=1}^{t-1} \text{cov}(y_t, u_{t-h}) + \frac{c}{n} \lim_{t \to \infty} \sum_{h=1}^{t-1} \sum_{k=0}^{t-h-2} \left(1 + \frac{c}{n}\right)^k \text{cov}(y_t, u_{t-h-1-k}).
\]

The first term converges to \( \sum_{h=1}^\infty \text{cov}(y_t, u_{t-h}) \). The second term is bounded by \( \frac{c}{n} \sum_{h=0}^\infty (h+1) | \text{cov}(y_t, u_{t-h})| = O(n^{-1}) \), and the stated result follows.

### 8.2 Proof of Lemma 1

\[
\frac{n}{m} \text{var}\left( \hat{\lambda}_{y, \Delta x} \right) = \frac{n}{m} \sum_{h'=1}^{n-1} \sum_{h=1}^{n-1} k \left( \frac{h'-1}{m} \right) k \left( \frac{h-1}{m} \right) \text{cov}\left( \hat{\Gamma}_{xy} (h'), \hat{\Gamma}_{xy} (h) \right). \tag{32}
\]

Hannan (1970) p. 313 gives

\[
\text{cov}\left( \hat{\Gamma}_{xy} (h'), \hat{\Gamma}_{xy} (h) \right) = n^{-1} \sum_{u=-\infty}^{\infty} \{ \Gamma_{\Delta x \Delta x}(u) \Gamma_{yy}(u+h-h') + \Gamma_{\Delta x y}(u+h) \Gamma_{y \Delta x}(u-h') \}
\]

\[+ k_{\Delta x y \Delta x y}(0, h', u, u+h) \phi_n(u, h', h), \]

where \( k_{\Delta x y \Delta x y}(0, h', u, u+h) \) is the fourth cumulant of \( z_t \) (see Hannan, 1970, p.23 for the definition) and \( \phi_n(u, h', h) \) is given by (the formula of \( \phi_n(u, h', h) \) for \( -n+h' \leq u \leq 0 \) in Hannan has a typo)

\[
\phi_n(u, h', h) \begin{cases} 
0, & u \leq -n+h'; \\
1 - \frac{h'-u}{n}, & -n+h' \leq u \leq 0; \\
1 - \frac{h+u}{n}, & h' - u \leq u \leq n - h;
\end{cases}
\]

It follows that (32) is comprised of

\[
\frac{1}{m} \sum_{h'=1}^{n-1} \sum_{h=1}^{n-1} k \left( \frac{h'-1}{m} \right) k \left( \frac{h-1}{m} \right) \sum_{u=-\infty}^{\infty} \Gamma_{\Delta x \Delta x}(u) \Gamma_{yy}(u+h-h') \phi_n(u, h', h) \tag{34}
\]

\[
+ \frac{1}{m} \sum_{h'=1}^{n-1} \sum_{h=1}^{n-1} k \left( \frac{h'-1}{m} \right) k \left( \frac{h-1}{m} \right) \sum_{u=-\infty}^{\infty} \Gamma_{\Delta x y}(u+h) \Gamma_{y \Delta x}(u-h') \phi_n(u, h', h) \tag{35}
\]

\[
+ \frac{1}{m} \sum_{h'=1}^{n-1} \sum_{h=1}^{n-1} k \left( \frac{h'-1}{m} \right) k \left( \frac{h-1}{m} \right) \sum_{u=-\infty}^{\infty} k_{\Delta x y \Delta x y}(0, h', u, u+h) \phi_n(u, h', h). \tag{36}
\]
Let \( v = h' - h \), and we can rewrite (34) as

\[
\sum_{v=-n+2}^{n-2} \sum_{u=-\infty}^{\infty} \Gamma_{\Delta x \Delta x}(u) \Gamma_{yy}(u-v) \left\{ \frac{1}{m} \sum_{h} \phi_{n}(u, h + v, h) k\left(\frac{h + v - 1}{m}\right) k\left(\frac{h - 1}{m}\right) \right\},
\]

(37)

where the summation \( \sum_{h} \) runs only for \( \{ h : 1 \leq h \leq n-1 \text{ and } 1 \leq h + v \leq n-1 \} \). The bracketed expression converges to \( \int_{0}^{\infty} k^{2}(x) \, dx \) by the argument in Hannan (1970) pp. 314–15. Furthermore, \( \sum_{v=-n+2}^{n-2} \sum_{u=-\infty}^{\infty} \Gamma_{\Delta x \Delta x}(u) \Gamma_{yy}(u-v) \to 4\pi^{2} \int_{\Delta x} f_{\Delta x}(0) f_{yy}(0) \) as \( n \to \infty \), and hence (34) converges to \( V \).

For (35), define \( u' = u + h \) and rewrite (35) as

\[
\sum_{u'=-\infty}^{\infty} \Gamma_{\Delta xy}(u') \frac{1}{m} \sum_{h'=-1}^{n-1} \sum_{h=1}^{n-1} k\left(\frac{h' - 1}{m}\right) k\left(\frac{h - 1}{m}\right) \Gamma_{\Delta x}(u' - h - h') \phi_{n}(u' - h, h', h).
\]

(38)

Let \( \beta \in (0,1/2) \) and split the sum into three: (i) \( |u'| \geq \log m \), (ii) \( |u'| < \log m \) and \( h + h' \leq m^{\beta} \), and (iii) \( |u'| < \log m \) and \( h + h' > m^{\beta} \). For (i), the sum is bounded by

\[
\sum_{|u'| \geq \log m} |\Gamma_{\Delta xy}(u')| \frac{1}{m} \sum_{h=1}^{n-1} \left| k\left(\frac{h - 1}{m}\right) \right| \left| \sum_{h'=1}^{n-1} |\Gamma_{\Delta x}(u' - h - h')| \sup_{x} |k(x)| \right. \left. \to 0,
\]

since \( \sum_{|u'| \geq \log m} |\Gamma_{\Delta xy}(u)| < \infty \) and thus the tail sum is \( o(1) \). For (ii), the sum is bounded by

\[
\sum_{|u'| < \log m} |\Gamma_{\Delta xy}(u')| \frac{1}{m} \left[ \sum_{h=1}^{m^{\beta}} \left| k\left(\frac{h - 1}{m}\right) \right| \right]^{2} \sup_{u} |\Gamma_{\Delta x}(u)| = O\left( m^{2\beta - 1} \right) \to 0.
\]

For (iii), define \( v = u' - h - h' \) and note that \( |v| \geq m^{\beta}/2 \) for sufficiently large \( m \). Thus, the sum is bounded by

\[
\sum_{|v'| < \log m} |\Gamma_{\Delta xy}(u')| \frac{1}{m} \sum_{h=1}^{n-1} \left| k\left(\frac{h - 1}{m}\right) \right| \sum_{v \geq m^{\beta}/2} |\Gamma_{\Delta x}(v)| |v| (m^{\beta}/2)^{-1} \sup_{x} |k(x)| = O(m^{-\beta}),
\]

since \( \sum_{v=-\infty}^{\infty} |\Gamma_{\Delta x}(v)| |v| < \infty \) by (10). Hence (35) converges to 0. (36) is \( O(m^{-1}) \) because the fourth cumulant of \( z_{t} \) satisfies (Hannan, 1970, p. 211)

\[
\sum_{q=-\infty}^{\infty} \sum_{r=-\infty}^{\infty} \sum_{s=-\infty}^{\infty} |k_{ijkl}(0, q, r, s)| < \infty, \quad i, j, k, l = \{ y, \Delta x \},
\]

(39)

and the stated result follows. \( \blacksquare \)
8.3 Proof of Theorem 2

In view of Lemma 1, it suffices to show that \( \sqrt{n/m(\hat{\lambda}_y, \Delta x - E\hat{\lambda}_y, \Delta x)} \to_d N(0, V) \).

First, observe that

\[
\frac{1}{\sqrt{n/m}} \left( \hat{\lambda}_y, \Delta x - E\hat{\lambda}_y, \Delta x \right) = I + II,
\]

where

\[
I = \frac{1}{\sqrt{n/m}} \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \frac{1}{\sqrt{n}} \sum_{t=h+1}^{n} (y_t \Delta x_{t-h} - E y_t \Delta x_{t-h}) \quad \text{and} \quad II = -\frac{1}{\sqrt{n/m}} \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \frac{1}{\sqrt{n}} \sum_{t=1}^{h} (y_t \Delta x_{t-h} - E y_t \Delta x_{t-h}).
\]

From Lemma 11, Minkowski’s inequality, \( \int_0^\infty |k(x)|x^{1/2}dx < \infty \), and an argument similar to Lemma 1 of Jansson (2002), we have

\[
E(II)^2 = O \left( \frac{1}{mn} \left( \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) |h^{1/2}| \right)^2 \right) = O \left( \frac{m^2}{n} \right),
\]

Lemma 13 gives

\[
I = \sum_{t=1}^{n} Z_t + R_n; \quad Z_t = n^{-1/2} m^{-1/2} \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \sum_{r=1}^{\infty} \varepsilon'_{t-r} f^{hr}(1) \varepsilon_t,
\]

where \( ER_n^2 = o(1) \) and \( f^{hr}(1) \) is defined in the statement of Lemma 13. Therefore, \( \sqrt{n/m(\hat{\lambda}_y, \Delta x - E\hat{\lambda}_y, \Delta x)} \to_d N(0, V) \) follows if we show that

\[
\sum_{t=1}^{n} Z_t \to_d N(0, V), \quad \text{as} \ n \to \infty.
\]

Let \( \mathcal{I}_t = \sigma(\varepsilon_t, \varepsilon_{t-1}, \ldots) \). Since \( Z_t \in \mathcal{I}_t \) and \( E(Z_t|\mathcal{I}_{t-1}) = 0 \), \( Z_t \) is a martingale difference sequence and (43) follows from the martingale CLT of Brown (1971) if

\[
\sum_{t=1}^{n} E(Z_t^2|\mathcal{I}_{t-1}) = \frac{1}{n} \sum_{t=1}^{n} E(n Z_t^2|\mathcal{I}_{t-1}) \to_p V,
\]

(i) \( \sum_{t=1}^{n} E(Z_t^2 1_{\{|Z_t| \geq \delta\}}) \to_p 0 \quad \text{for all} \ \delta > 0. \)

First we show (i). Observe that

\[
E(n Z_t^2|\mathcal{I}_{t-1}) = m^{-1} \sum_{h=1}^{n-1} \sum_{u=1}^{n-1} k \left( \frac{h-1}{m} \right) k \left( \frac{u-1}{m} \right) \sum_{r=1}^{\infty} \sum_{s=1}^{\infty} \varepsilon'_{t-r} f^{hr}(1)(f^{us}(1))' \varepsilon_{t-s}.
\]
$E(nZ_t^2|\mathcal{I}_{t-1})$ is stationary and ergodic because $\varepsilon_t$ is i.i.d. Furthermore, from the law of iterated expectations we have

$$E \left[ E(nZ_t^2|\mathcal{I}_{t-1}) \right] = nEZ_t^2.$$ 

Therefore, (i) follows from the ergodic theorem if

$$nEZ_t^2 \to V.$$  \hspace{1cm} (44)

From (40)-(42), we have

$$\sqrt{\frac{n}{m}} \left( \hat{\lambda}_{y,\Delta x} - E\hat{\lambda}_{y,\Delta x} \right) = \sum_{t=1}^n Z_t + II + R_n, \quad E(II + R_n)^2 = o(1),$$

or equivalently,

$$\sum_{t=1}^n Z_t = \sqrt{\frac{n}{m}} \left( \hat{\lambda}_{y,\Delta x} - E\hat{\lambda}_{y,\Delta x} \right) - (II + R_n).$$

Taking the second moment of the both sides gives

$$E \left( \sum_{t=1}^n Z_t \right)^2 = E \left( \sqrt{\frac{n}{m}} \left( \hat{\lambda}_{y,\Delta x} - E\hat{\lambda}_{y,\Delta x} \right) - (II + R_n) \right)^2.$$  \hspace{1cm} (45)

The left hand side of (45) is $\sum_{t=1}^n EZ_t^2 = nEZ_t^2$, since $Z_t$ is a stationary martingale difference sequence. The right hand side of (45) is

$$\text{var} \left( \sqrt{\frac{n}{m}} \left( \hat{\lambda}_{y,\Delta x} - E\hat{\lambda}_{y,\Delta x} \right) \right)^2 + o(1) \to V,$$

because

$$E \left( \sqrt{\frac{n}{m}} \left( \hat{\lambda}_{y,\Delta x} - E\hat{\lambda}_{y,\Delta x} \right) \right)^2 = \text{var} \left( \sqrt{\frac{n}{m}} \left( \hat{\lambda}_{y,\Delta x} - E\hat{\lambda}_{y,\Delta x} \right) \right) \to V,$$

and $E(II + R_n)^2 = o(1)$.

Therefore, we establish (44) and (i). For (ii), the stationarity of $Z_t$ gives $\sum_{t=1}^n E(Z_t^2 1\{ |Z_t| \geq \delta \}) = E(nZ_t^2 1\{ |nZ_t^2| \geq n\delta^2 \})$, and $E(nZ_t^2 1\{ |nZ_t^2| \geq n\delta^2 \}) \to 0$ follows from $E(nZ_t^2) \to V < \infty$ and the dominated convergence theorem, giving (43) and the stated result follows. \rule{2mm}{2mm}

### 8.4 Proof of Lemma 3

From (31), we have

$$\frac{1}{n} \sum_{t=h+1}^n y_t \Delta x_{t-h} = \frac{1}{n} \sum_{t=h+1}^n y_t u_{t-h} + T_{nh}, \quad T_{nh} = \frac{c}{n^2} \sum_{t=h+1}^n \sum_{k=0}^{t-h-2} \left( 1 + \frac{c}{n} \right)^k y_t u_{t-h-1-k}.$$ 

The required result follows because $E| \sum_{h=1}^{n-1} k((h-1)/m)|T_{nh} |$ is bounded by $n^{-2} \sum_{h=1}^{n-1} |k((h-1)/m)| \sum_{t=h+1}^n \sum_{k=-\infty}^{\infty} |\Gamma_{uy}(k)| = O(n^{-1} \sum_{h=1}^{n-1} |k((h-1)/m)|) = O(mn^{-1})$. \rule{2mm}{2mm}
8.5 Proof of Lemma 4

Some simple algebra gives

\[ \hat{\lambda}_{y,\Delta x} = \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \frac{1}{n} \sum_{t=h+1}^{n} y_t \Delta x_{t-h} \]

\[ = \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \frac{1}{n} \sum_{t=h+1}^{n} y_t \Delta x_{t-h} - \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \frac{1}{n} \sum_{t=h+1}^{n} y_t \Delta x_{t-h-1} \]

\[ = \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \frac{1}{n} \sum_{t=h+1}^{n} y_t \Delta x_{t-h} - \sum_{p=2}^{n} k \left( \frac{p-2}{m} \right) \frac{1}{n} \sum_{t=p}^{n} y_t \Delta x_{t-p} \quad (p = h + 1) \]

\[ = \frac{1}{n} \sum_{t=2}^{n} y_t \Delta x_{t-1} + \sum_{h=2}^{n-1} \left[ k \left( \frac{h-1}{m} \right) - k \left( \frac{h-2}{m} \right) \right] \frac{1}{n} \sum_{t=h+1}^{n} y_t \Delta x_{t-h} \]

\[ - \sum_{p=2}^{n-1} k \left( \frac{p-2}{m} \right) \frac{1}{n} y_p x_0 - k \left( \frac{n-2}{m} \right) \frac{1}{n} y_n x_0 \]

\[ = T_{1n} + T_{2n} + T_{3n} + T_{4n}. \]

For \( T_{1n} \), we have from Theorem 14 of Hannan (1970, page 228) (note that \( \hat{\lambda}_{y,\Delta x} = E y_t \Delta x_{t-1} = \gamma_{xy}(1) \))

\[ \sqrt{n} (T_{1n} - \hat{\lambda}_{y,\Delta x}) = \sqrt{n} (\hat{\gamma}_{xy}(1) - \gamma_{xy}(1)) \rightarrow_d N(0, \Xi), \]

as \( n \rightarrow \infty \), where \( \Xi \) is given by Hannan (1970) in equation (3.3) on page 209 and line 5 on page 211. For \( T_{2n} \), first observe that

\[ E(T_{2n}) = \sum_{h=2}^{n-1} \left[ k \left( \frac{h-1}{m} \right) - k \left( \frac{h-2}{m} \right) \right] \frac{n-h}{n} \gamma_{xy}(h). \]

\[ ET_{2n} = 0 \] when \( E y_t \Delta x_{t-h} = \gamma_{xy}(h) = 0 \) for all \( h \geq 2 \). Otherwise, fix a small \( \varepsilon > 0 \), then

\[ E|T_{2n}| \leq \sum_{h=2}^{\varepsilon m} \left| k \left( \frac{h-1}{m} \right) - k \left( \frac{h-2}{m} \right) \right| \left| \gamma_{xy}(h) \right| + C \sum_{h=\varepsilon m+1}^{n-1} \left| \gamma_{xy}(h) \right|. \]

Since \( k(x) - 1 = O(x^q) \) as \( x \rightarrow 0 \), the first term on the right is, for \( \varepsilon \) sufficiently small, \( O(\sum_{h=2}^{\varepsilon m}(h/m)^q|\gamma_{xy}(h)|) = O(m^{-q}) \). The second term on the right is bounded by \( \sum_{h=\varepsilon m}^{n-1} \left| \gamma_{xy}(h) \right| \leq (\varepsilon m)^{-q} \sum_{h=\varepsilon m}^{n-1} h^q \left| \gamma_{xy}(h) \right| = O(m^{-q}) \). Therefore, defining \( B_n = \sqrt{n} ET_{2n} \) gives the bias term \( B_n \) in (15).

It remains to show that \( \text{var}(\sqrt{n}T_{2n}) = o(1) \) and \( \sqrt{n}(T_{3n} + T_{4n}) = o_p(1) \). From
Hannan (1970) (equation (3.3) on page 209 and line 5 on page 211), we have
\[
\text{cov}
\left( \sqrt{n} \hat{\gamma}_{xy}(h), \sqrt{n} \hat{\gamma}_{xy}(h') \right)
= \sum_{u=-n+1}^{n-1} \left( 1 - \frac{|u|}{n} \right) \{ \gamma_{xx}(u) \gamma_{yy}(u-h-h') + \gamma_{xy}(u+h) \gamma_{yx}(u-h') \}
+ \sum_{u=-n+1}^{n-1} \left( 1 - \frac{|u|}{n} \right) k_{xyxy}(0, h, u, u + h').
\]
Therefore, from the Lipschitz condition on \( k(\cdot) \), the terms composing the variance of \( \sqrt{n} T_{2n} \) that do not involve \( k_{xyxy} \) are bounded by
\[
\frac{1}{m^2} \sum_{h=1}^{m} \sum_{h'=1}^{m} \sum_{u=-n+1}^{n-1} \left| \gamma_{xx}(u) \gamma_{yy}(u-h-h') + \gamma_{xy}(u+h) \gamma_{yx}(u-h') \right|
\leq \frac{1}{m} \left[ \sum_{u=-\infty}^{\infty} |\gamma_{xx}(u)| \sum_{h=-\infty}^{\infty} |\gamma_{yy}(h)| + \sum_{h=-\infty}^{\infty} \left| \gamma_{xy}(u) \right| \sum_{h'=\infty}^{\infty} \left| \gamma_{yx}(h') \right| \right] = O(m^{-1}).
\]
The term in the variance of \( \sqrt{n} T_{2n} \) that involves \( k_{xyxy} \) is bounded by
\[
\frac{1}{m^2} \sum_{h=1}^{m} \sum_{h'=1}^{m} \sum_{u=-n+1}^{n-1} \left| k_{xyxy}(0, h, u, u + h') \right| = O(m^{-2}),
\]
because \( \sum_{h=-\infty}^{\infty} \sum_{h'=\infty}^{\infty} \sum_{s=-\infty}^{\infty} |k_{xyxy}(0, q, r, s)| < \infty \) from Hannan (1970, p. 211).
Finally, \( \sqrt{n} (T_{3n} + T_{4n}) = o_p(1) \) follows from
\[
\sqrt{n} (T_{3n} + T_{4n}) = \sum_{p=2}^{n} k \left( \frac{p-2}{m} \right) \frac{1}{\sqrt{n}} y_p x_0,
\]
x_0 = O_p(1), and
\[
E \left( \sum_{p=2}^{n} k \left( \frac{p-2}{m} \right) \frac{1}{\sqrt{n}} y_p \right)^2 \leq \frac{m}{n} \sum_{v=-n+2}^{n-2} \left| \gamma_{yy}(v) \right| \left[ \frac{1}{m} \sum_{h=2}^{n} k \left( \frac{h-2}{m} \right) k \left( \frac{v+h-2}{m} \right) \right] = O \left( \frac{m}{n} \right),
\]
and the stated result follows. ■

8.6 Proof of Lemma 5

In view of equations (34) and (37) in the proof of Lemma 1, \( \tilde{V} \) reduces to
\[
\sum_{v=-n+2}^{n-2} \sum_{u=-\infty}^{\infty} \hat{k} \left( \frac{u}{m} \right) \hat{\Gamma}_{\Delta x \Delta x}(u) \hat{k} \left( \frac{u-v}{m} \right) \hat{\Gamma}_{yy}(u-v) \left\{ \int_{0}^{\infty} k^2(x) dx + o(1) \right\}.
\]
Because \( \tilde{k}(x) = 0 \) for \(|x| > 1\) and \(\tilde{m}/n \to 0\), this simplifies to
\[
\sum_{u=-\tilde{m}}^{\tilde{m}} \tilde{k} \left( \frac{u}{\tilde{m}} \right) \tilde{\Gamma}_{\Delta x}(u) \sum_{v=-\tilde{m}}^{\tilde{m}} \tilde{k} \left( \frac{u-v}{\tilde{m}} \right) \tilde{\Gamma}_{yy}(u-v) \left\{ \int_0^\infty k^2(x) \, dx + o(1) \right\},
\]
which converges to \(4\pi^2 f_{\Delta x}(0) f_{yy}(0) \int_0^\infty k^2(x) \, dx\) in probability by the standard argument. The result for the local-to-unity case follows from the proof of Lemma 3.

\[\blacksquare\]

### 8.7 Proof of Lemma 7

The Lemma follows if we show that there exists \(\eta > 0\) such that
\[
\Pr(\tilde{V} \geq \eta \tilde{m}^{-1}) \to 1, \quad \text{as } n \to \infty. \tag{46}
\]
From the arguments in the proof of Lemma 5, \(\tilde{V}\) is equal to
\[
\sum_{u=-\tilde{m}}^{\tilde{m}} \tilde{k} \left( \frac{u}{\tilde{m}} \right) \tilde{\Gamma}_{\Delta x}(u) \sum_{v=-\tilde{m}}^{\tilde{m}} \tilde{k} \left( \frac{v}{\tilde{m}} \right) \tilde{\Gamma}_{yy}(v) \left\{ \int_0^\infty k^2(x) \, dx + o(1) \right\} \tag{47}
\]
Because \(\sum_{v=-\tilde{m}}^{\tilde{m}} \tilde{k}(v/\tilde{m}) \tilde{\Gamma}_{yy}(v) \to 2\pi f_{yy}(0) > 0\) by the standard argument, (46) follows if there exists \(\varepsilon > 0\) such that
\[
\Pr \left( \sum_{v=-\tilde{m}}^{\tilde{m}} \tilde{k} \left( \frac{v}{\tilde{m}} \right) \tilde{\Gamma}_{\Delta x}(v) \geq \varepsilon \tilde{m}^{-1} \right)
= \Pr \left( 2\pi \int_{-\pi}^{\pi} W_{\tilde{m}}(\lambda) I_{\Delta x}(\lambda) d\lambda \geq \varepsilon \tilde{m}^{-1} \right) \to 1, \quad \text{as } n \to \infty, \tag{48}
\]
where (Priestley, 1981, p. 439)
\[
W_{\tilde{m}}(\lambda) = \frac{1}{2\pi} \sum_{h=-\tilde{m}}^{\tilde{m}} \tilde{k} \left( \frac{h}{\tilde{m}} \right) e^{i\lambda h} = \frac{1}{2\pi \tilde{m}} \frac{\sin^2(\tilde{m}\lambda/2)}{\sin^2(\lambda/2)} \geq 0,
\]
is the Fejér kernel. From Phillips (1999, Theorem 2.2 and Remark 2.4), we have
\[
w_{\Delta x}(\lambda) = \left( 1 - e^{i\lambda} \right) w_x(\lambda) + e^{i(n+1)\lambda}(2\pi n)^{-1/2} X_n.
\]
It follows that
\[
\int_{-\pi}^{\pi} W_{\tilde{m}}(\lambda) I_{\Delta x}(\lambda) d\lambda
= \int_{-\pi}^{\pi} W_{\tilde{m}}(\lambda) \left| 1 - e^{i\lambda} \right|^2 I_x(\lambda) d\lambda \tag{49}
\]
\[
+ (2\pi n)^{-1/2} X_n \int_{-\pi}^{\pi} W_{\tilde{m}}(\lambda) 2\text{Re} \left[ (1 - e^{i\lambda}) w_x(\lambda) e^{-i(n+1)\lambda} \right] d\lambda \tag{50}
\]
\[
+ \int_{-\pi}^{\pi} W_{\tilde{m}}(\lambda) d\lambda (2\pi n)^{-1} X_n^2. \tag{51}
\]
We can ignore (51) because it is nonnegative. For (50), it follows from the Cauchy-Schwartz inequality and Lemma 14 (b) that
\[
\int_{-\pi}^{\pi} W_\tilde{m}(\lambda) 2\text{Re} \left[ (1 - e^{i\lambda})w_x(\lambda)e^{-i(n+1)\lambda} \right] d\lambda \\
\leq \left( \int_{-\pi}^{\pi} W_\tilde{m}(\lambda) \left| 2\text{Re} \left[ (1 - e^{i\lambda})w_x(\lambda)e^{-i(n+1)\lambda} \right] \right|^2 d\lambda \right)^{1/2} \left( \int_{-\pi}^{\pi} W_\tilde{m}(\lambda) d\lambda \right)^{1/2} \\
= O_p \left( \left( \int_{-\pi}^{\pi} W_\tilde{m}(\lambda) \lambda^2 d\lambda \right)^{1/2} \right) = O_p(\tilde{m}^{-1/2}),
\]
and (50) = $O_p(n^{-1/2}\tilde{m}^{-1/2}) = o_p(\tilde{m}^{-1})$ follows. Rewrite (49) as
\[
\int_{-\pi}^{\pi} W_\tilde{m}(\lambda) |1 - e^{i\lambda}|^2 EI_x(\lambda) d\lambda \\
+ \int_{-\pi}^{\pi} W_\tilde{m}(\lambda) |1 - e^{i\lambda}|^2 (I_x(\lambda) - EI_x(\lambda)) d\lambda \\
= A_1 + A_2.
\]
For $A_1$, because $\tilde{f}_{xx}(0) > 0$ and $\tilde{f}_{xx}(\lambda)$ is continuous in the neighborhood of the origin since $\sum j ||B_j|| < \infty$, there exist $D \in (0,1)$ and $c_1, c_2 > 0$ such that, for sufficiently large $n$ (Hannan, Theorem 2, p. 248)
\[
\inf_{\lambda \in [-D\pi, D\pi]} |1 - e^{i\lambda}|^2 \lambda^{-2} \geq c_1, \quad \inf_{\lambda \in [-D\pi, D\pi]} EI_x(\lambda) \geq c_2.
\]
Therefore, in conjunction with Lemma 14 (a), we obtain
\[
A_1 \geq c_1 c_2 \int_{-D\pi}^{D\pi} W_\tilde{m}(\lambda) \lambda^2 d\lambda \geq c_1 c_2 \kappa \tilde{m}^{-1}, \quad \kappa > 0.
\]
For $A_2$, it follows from Theorem 2 and Corollary 1 of Hannan (1970, pp. 248-9) and their proof that
\[
\left\{ \begin{array}{l}
\sup_{\lambda, \lambda' \in [-\pi, \pi]} \left| \text{cov} \left( I_x(\lambda), I_x(\lambda') \right) \right| = O(1), \\
\text{cov} \left( I_x(\lambda), I_x(\lambda') \right) = o(1), \quad \lambda \neq \lambda'.
\end{array} \right. \tag{52}
\]
Therefore,
\[
E(A_2)^2 = \int_{-\pi}^{\pi} \int_{-\pi}^{\pi} W_\tilde{m}(\lambda) W_\tilde{m}(\lambda') |1 - e^{i\lambda}|^2 |1 - e^{i\lambda'}|^2 \text{cov} \left( I_x(\lambda), I_x(\lambda') \right) d\lambda d\lambda' \\
\leq C \int_{-\pi}^{\pi} \int_{-\pi}^{\pi} W_\tilde{m}(\lambda) W_\tilde{m}(\lambda') \lambda^2(\lambda')^2 \left| \text{cov} \left( I_x(\lambda), I_x(\lambda') \right) \right| d\lambda d\lambda' \\
= o(\tilde{m}^{-2})
\]
where the interchange of expectation and integration in the first line is valid by (52) and Fubini’s Theorem, and the last line follows from Lemma 14 (b), (52), and the dominated convergence theorem. Therefore, there exists $\eta' > 0$ such that $(49) + (50) + (51) \geq \eta' \tilde{m}^{-1}$ with probability approaching one, and (48) and the stated result follow. ■
8.8 Proof of Lemma 9

Assume $x_0 = 0$ without the loss of generality. We show part (a) first. Substituting $y_t = \beta_n x_{t-1} + u_t$ into $\hat{\lambda}_{y, \Delta x}$, we have

$$\hat{\lambda}_{y, \Delta x} = \beta_n \sum_{h=1}^{n-1} k\left(\frac{h-1}{m}\right) \frac{1}{n} \sum_{t=h+1}^{n} x_{t-1} \Delta x_{t-h} + \hat{\lambda}_{u, \Delta x},$$

(53)

where the second term is $O_p((m/n)^{1/2})$ from Lemma 1. If we show

$$\frac{1}{n} \sum_{t=h+1}^{n} x_{t-1} \Delta x_{t-h} = \frac{1}{n} \sum_{t=1}^{n} x_{t-1} \Delta x_{t} + \sum_{j=0}^{\infty} \Gamma_{\Delta x \Delta x}(j) + R_{nh},$$

(54)

with $E|R_{nh}| = O(n^{-1/2} h^2 + n^{-1/2} h)$, then the stated result follows from $n^{-1} \sum_{t=1}^{n} x_{t-1} \Delta x_{t} \to_d (1/2)(B^2(1) - \Gamma_{\Delta x \Delta x}(0))$.

To show (54), first rewrite the left hand side of (54) as

$$\sum_{t=h+1}^{n} x_{t-1} \Delta x_{t-h} = \sum_{t=1}^{n} x_{t-h} \Delta x_{t} - \frac{1}{n} \sum_{t=1}^{n} (\Delta x_{t} + \cdots + \Delta x_{t}) \Delta x_{t} + \frac{1}{n} \sum_{t=1}^{n} x_{t-1} \Delta x_{t}.$$  

(55)

The first term on the right of (55) equals $\sum_{j=0}^{h-1} \hat{\Gamma}_{\Delta x \Delta x}(j) + r_{nhj}$ with $E|r_{nhj}| = O(n^{-1}(h-j))$. Then $E|\sum_{j=0}^{h-1} r_{nhj}| = O(n^{-1} h^2)$. Now $\sum_{j=0}^{h-1} \hat{\Gamma}_{\Delta x \Delta x}(j)$ is an estimate of $\sum_{j=0}^{\infty} \Gamma_{\Delta x \Delta x}(j)$ with a rectangular kernel (i.e., $q = \infty$) and hence $\sum_{j=0}^{\infty} \Gamma_{\Delta x \Delta x}(j) + r_{nh}$, where $E|r_{nh}| = O(n^{-1/2} h^{1/2})$ from Lemma 1. The second term on the right of (55) equals $n^{-1} \sum_{t=1}^{n} x_{t-1} \Delta x_{t} + r_{nh}$ with $E|r_{nh}| \leq Cn^{-1/2} h$ from the Cauchy-Schwartz inequality. Therefore, we show (54) and complete the proof of part (a).

We proceed to prove part (b). From the arguments in the proof of Lemma 5, $\hat{V}$ is equal to $\sum_{u=-\widehat{m}}^{\widehat{m}} \hat{k}(u/\widehat{m}) \hat{\Gamma}_{\Delta x \Delta x}(u) \sum_{v=-\widehat{m}}^{\widehat{m}} \hat{k}(v/\widehat{m}) \hat{\Gamma}_{yy}(v) \left\{ \int_{0}^{\infty} k^2(x) \, dx + o(1) \right\}$. A standard argument gives $\sum_{u=-\widehat{m}}^{\widehat{m}} \hat{k}(u/\widehat{m}) \hat{\Gamma}_{\Delta x \Delta x}(u) \to_p 2\pi \Gamma_{\Delta x \Delta x}(0)$. Rewrite $\hat{\Gamma}_{yy}(v)$ as $\hat{\Gamma}_{yy}(v) = n^{-1} \sum_{t=1}^{n} y_{t} y_{t+v} = G_{1v} + G_{2v} + G_{3v} + G_{4v}$, where

$$G_{1v} = \beta_{n}^{2} n^{-1} \sum_{t=1}^{n-v} x_{t-1} x_{t-1+v}, \quad G_{2v} = \beta_{n} n^{-1} \sum_{t=1}^{n-v} u_{t} x_{t-1+v}, \quad G_{3v} = \beta_{n} n^{-1} \sum_{t=1}^{n-v} u_{t} x_{t-1+v}, \quad G_{4v} = n^{-1} \sum_{t=1}^{n-v} u_{t} u_{t+v}.$$

We consider $G_{2v}$ first. Note that, in view of $x_0 = 0$, with $h = t - s$,

$$\frac{G_{2v}}{\beta_{n}} = \frac{1}{n} \sum_{t=2}^{n-v} \sum_{s=1}^{v} x_{s} u_{t-s+v} = \frac{1}{n} \sum_{h=1}^{n-v} x_{h} u_{h+v} = \sum_{h=1}^{n-v} \hat{\Gamma}_{\Delta xu}(h+v).$$

$E[\sum_{h=0}^{n-v} \hat{\Gamma}_{\Delta xu}(h+v)]^2 = O(1)$ easily follows from the covariance between $\hat{\Gamma}_{\Delta xu}(h+v)$ and $\hat{\Gamma}_{\Delta xu}(h'+v)$ given by (33), and hence we have $\sum_{v=-\widehat{m}}^{\widehat{m}} \hat{k}(v/\widehat{m}) G_{2v} = O_p(\beta_{n} \widehat{m})$. A similar argument gives $\sum_{v=-\widehat{m}}^{\widehat{m}} \hat{k}(v/\widehat{m}) G_{3v} = O_p(\beta_{n} \widehat{m})$. For $G_{1v}$, it follows from the Cauchy-Schwartz inequality that

$$\frac{1}{n} \sum_{t=1}^{n-v} x_{t-1} x_{t-1+v} - \frac{1}{n} \sum_{t=1}^{n-v} x_{t-1}^{2} = r_{nv}, \quad E|r_{nv}| = O(v + n^{1/2} v^{1/2}),$$

35
and hence \((\beta_n^2\eta)\sum_{v=-n}^m \tilde{k}(v/\eta)G_{1v} \to_d \int_0^1 \tilde{k}(x)dx \int_0^1 B^2(r)dr.\) Finally, the stated result follows because \(\sum_{v=-n}^m \tilde{k}(v/\eta)G_{4v} \to_p 2\pi f_{uu}(0).\)

9 Appendix B: technical results

Lemma 11 Under the assumptions of Theorem 2,

\[ E \left( \sum_{t=1}^h (y_t \Delta x_{t-h} - E_y \Delta x_{t-h}) \right)^2 = O(h), \quad h = 1, \ldots, n - 1. \]

Proof Observe that

\[ E \left( \sum_{t=1}^h (y_t \Delta x_{t-h} - E_y \Delta x_{t-h}) \right)^2 = \text{var} \left( \sum_{t=1}^h y_t \Delta x_{t-h} \right) \leq E \left( \sum_{t=1}^h y_t \Delta x_{t-h} \right)^2. \]

From the product theorem (e.g. Hannan, 1970, pp. 23, 209), \(E(\sum_{t=1}^h y_t \Delta x_{t-h})^2\) is equal to (recall \(\Gamma\))

\[ E \left( \sum_{t=1}^h y_t \Delta x_{t-h} \right)^2 \]

The first term on the right is bounded by \(\sup_s |\Gamma\Delta x(s)|^2 < \infty.\) The second and third terms on the right are bounded by \(h \sup_s |\Gamma(s)||\sum_{l=-\infty}^{l=\infty} |\Gamma(l)|| \leq C.\) From (39), the fourth term on the right is bounded by \(h \sum_{l=-\infty}^{l=\infty} \sum_{r=-\infty}^{r=\infty} |k_{\Delta x y \Delta x}(0, -r, l - r)| \leq C.\) And the stated result follows.

Lemma 12 Define \(\tilde{f}_{jr}(L) = \sum_{j=0}^{\infty} \tilde{f}_{jr}^j \hat{L}^j\) with \(\tilde{f}_{jr}^j = \sum_{s=j+1}^{\infty} [(A_{s-r}^2 + \alpha(A_{s-r}^2 + \alpha A_{s-r}^2)], \) where \(A_j^1\) and \(A_j^2\) are the first and second rows of \(A_j,\) respectively. Under the assumptions of Theorem 2, for \(h = 1, \ldots, n - 1,\)

\[ (a) \quad E \left( \text{tr} \left( \tilde{f}_{jr}^0(L) \varepsilon_t \varepsilon_t' \right) \right)^2 < \infty, \quad (b) \quad E \left( \text{tr} \left( \sum_{r=1}^{\infty} \tilde{f}_{jr}^h(L) \varepsilon_t \varepsilon_t' \right) \right)^2 < \infty. \]
Proof We need to show the result only for $t = n$, because $\varepsilon_t$ is i.i.d. For part (a), since $\text{tr}(\tilde{f}^h_0(L)\varepsilon_{n}\varepsilon_{n}^t) = \sum_{j=0}^{\infty} \text{tr}(\tilde{f}^h_0\varepsilon_{n-j}\varepsilon_{n-j}^t) = \sum_{j=0}^{\infty} \varepsilon_{n-j}^t\tilde{f}^h_0\varepsilon_{n-j}$, we have

\[
E\left(\text{tr}\left(\tilde{f}^h_0(L)\varepsilon_{n}\varepsilon_{n}^t\right)\right)^2 = \sum_{j=0}^{\infty} \sum_{k=0}^{\infty} E\left(\varepsilon_{n-j}^t\tilde{f}^h_0\varepsilon_{n-j}\varepsilon_{n-k}^t\tilde{f}^h_0\varepsilon_{n-k}\right)
\leq C \left(\sum_{j=0}^{\infty} ||\tilde{f}^h_0||^2\right) + C \sum_{j=0}^{\infty} ||\tilde{f}^h_0||^2.
\]

This is finite because, uniformly in $h = 1, \ldots, n - 1$,

\[
||\tilde{f}^h_0|| \leq \sum_{s=j+1}^{\infty} ||(A^2_s-\delta)A_s^1|| \leq \sup_r ||A_r||(j+1)^{-\delta} \sum_{s=j+1}^{\infty} s^\delta ||A_s|| \leq Cj^{-\delta},
\]

and $\delta > 1$.

For part (b), rewrite $\text{tr}(\sum_{r=1}^{\infty} \tilde{f}^r_0(L)\varepsilon_{n}^r)\varepsilon_{n-r}$ as

\[
\sum_{r=1}^{\infty} \sum_{j=0}^{\infty} \text{tr}(\tilde{f}^r_0\varepsilon_{n-j}\varepsilon_{n-r-j}) \sum_{r=0}^{\infty} \sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} \varepsilon_{n-j}^t(\tilde{f}^r_0)^t\varepsilon_{n-r-j} = \sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} \varepsilon_{n-j}^t\sum_{r=0}^{\infty} \sum_{j=0}^{\infty} \varepsilon_{n-r-j}^t\varepsilon_{n-r-j} = \sum_{j=0}^{\infty} \xi_{n-j}^h,
\]

where $\xi_{n-j}^h = \varepsilon_{n-j}^t\sum_{r=0}^{\infty} (\tilde{f}^r_0)^t\varepsilon_{n-r-j}$. Since $\xi_{n-j}^h \in I_{n-j} = \sigma(\varepsilon_{n-j}, \varepsilon_{n-j-1}, \ldots)$ and $E(\xi_{n-j}^h \mid I_{n-j-1}) = 0$, it follows that

\[
E\left(\sum_{j=0}^{\infty} \xi_{n-j}^h\right)^2 = \sum_{j=0}^{\infty} E(\xi_{n-j}^h)^2 \leq C \sum_{j=0}^{\infty} \sum_{r=0}^{\infty} ||\tilde{f}^r_0||^2 \leq C \left(\sup_{j,r} ||\tilde{f}^r_0||\right) \sum_{j=0}^{\infty} \sum_{r=0}^{\infty} ||\tilde{f}^r_0||.
\]

Observe that $\sup_h \sum_{j,r} ||\tilde{f}^r_0|| \leq \sup_p ||A_p|| \sum_{s=0}^{\infty} ||A_s|| < \infty$. Furthermore, uniformly in $h = 1, \ldots, n - 1$,

\[
\sum_{j=0}^{\infty} \sum_{r=1}^{\infty} ||\tilde{f}^r_0|| \leq \sum_{j=0}^{\infty} \sum_{r=1}^{\infty} \sum_{s=j+1}^{\infty} ||A_{s+r}|| ||A_s|| + \sum_{j=0}^{\infty} \sum_{r=1}^{\infty} \sum_{s=j+1}^{\infty} ||A_{s+r}|| ||A_{s-r}||
\leq \sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} ||A_s|| \sum_{r=0}^{\infty} ||A_r|| + \sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} ||A_{s-r}|| \sum_{r=0}^{\infty} ||A_r||.
\]

The first term in (57) is bounded by $\sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} ||A_s|| = \sum_{j=1}^{\infty} j ||A_j|| < \infty$. The

second term in (57) is bounded by $\sum_{j=0}^{\infty} \sum_{p=\max\{j-h+1,0\}}^{\infty} ||A_p|| = \sum_{j=0}^{\infty} \sum_{p=j-h+1}^{\infty} ||A_p|| = \sum_{s=1}^{\infty} \sum_{s+1}^{\infty} ||A_p|| = \sum_{s=1}^{\infty} s ||A_s|| < \infty$. Therefore, the right hand side of (56) is finite, and part (b) follows.

Lemma 13 Under the assumptions of Theorem 2,

\[
\frac{1}{\sqrt{m}} \sum_{h=1}^{n} k\left(\frac{h-1}{m}\right) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} (y_t \Delta x_{t-h} - E(y_t \Delta x_{t-h})) = \sum_{t=1}^{n} Z_t + R_n,
\]

37
where $ER_n^2 = o(1)$ and $Z_t = n^{-1/2}m^{-1/2} \sum_{h=1}^{n-1} k((h-1)/m) \sum_{r=1}^{\infty} \varepsilon_{t-r} f^{hr}(1) \varepsilon_t$, $f^{hr}(1) = \sum_{j=0}^{\infty} [(A^2_{j+r-h})' A^1_j + (A^1_{j+r})' A^2_{j-r}]$, and $A^1_j$ and $A^2_j$ denote the first and second row of $A_j$, respectively.

**Proof** The proof follows from an argument similar to Remark 3.9 (i) of Phillips and Solo (1992, p. 980). First, we find an alternate expression of $\sum_{t=1}^{n} y_t \Delta x_{t-h}$ so that it can be approximated by a martingale. Express $y_t$ and $\Delta x_t$ as

$$
\begin{pmatrix}
y_t \\
\Delta x_t
\end{pmatrix} =
\begin{pmatrix}
A^1(L) \varepsilon_t \\
A^2(L) \varepsilon_t
\end{pmatrix} =
\begin{pmatrix}
\sum_{j=0}^{\infty} A^1_j \varepsilon_{t-j} \\
\sum_{j=0}^{\infty} A^2_j \varepsilon_{t-j}
\end{pmatrix},
$$

where $A^1_j$ and $A^2_j$ are the first and second row of $A_j$, respectively. Observe that

$$y_t \Delta x_{t-h} = A^1(L) \varepsilon_t A^2(L) \varepsilon_{t-h}$$

$$= \sum_{j=0}^{\infty} A^1_j \varepsilon_{t-j} \sum_{h=0}^{\infty} A^2_h \varepsilon_{t-h-k}$$

$$= \sum_{j=0}^{\infty} A^1_j \varepsilon_{t-j} A^2_{s-h} \varepsilon_{t-s} + \sum_{j=0}^{\infty} A^1_j \varepsilon_{t-j} \sum_{s=0, s \neq j}^{\infty} A^2_s \varepsilon_{t-s}, \quad (s = h + k).$$

Since $A^2_{s-h} \varepsilon_{t-s}$ is a scalar, the first term on the right is

$$\text{tr} \left( \sum_{j=0}^{\infty} (A^2_{s-h})' A^1_j \varepsilon_{t-j} \varepsilon'_{t-s} \right) = \text{tr} \left( f^{h0}(L) \varepsilon_t \varepsilon'_{t} \right), \quad f^{h0}(L) = \sum_{j=0}^{\infty} (A^2_{j-h})' A^1_j L^j = \sum_{j=0}^{\infty} f^{h0}_j L^j.$$

The second term on the right is, since $A^2_s \equiv 0$ for $s < 0$,

$$\text{tr} \left( \sum_{j=0}^{\infty} \sum_{s=0, s \neq j}^{\infty} (A^2_{s-h})' A^1_j \varepsilon_{t-j} \varepsilon'_{t-s} \right)$$

$$= \text{tr} \left( \sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} (A^2_{s-h})' A^1_j \varepsilon_{t-j} \varepsilon'_{t-s} \right) + \text{tr} \left( \sum_{j=0}^{\infty} \sum_{s=0}^{\infty} (A^2_{s-h})' A^1_j \varepsilon_{t-j} \varepsilon'_{t-s} \right)$$

$$= \text{tr} \left( \sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} (A^2_{s-h})' A^1_j \varepsilon_{t-j} \varepsilon'_{t-s} \right) + \text{tr} \left( \sum_{s=0}^{\infty} \sum_{j=s+1}^{\infty} (A^2_j)' A^2_{s-h} \varepsilon_{t-s} \varepsilon'_{t-j} \right)$$

$$= \text{tr} \left( \sum_{j=0}^{\infty} \sum_{s=j+1}^{\infty} [(A^2_{s-h})' A^1_j + (A^1_s)' A^2_{j-h}] \varepsilon_{t-j} \varepsilon'_{t-s} \right)$$

$$= \text{tr} \left( \sum_{j=0}^{\infty} \sum_{r=1}^{\infty} [(A^2_{j+r-h})' A^1_j + (A^1_{j+r})' A^2_{j-r}] \varepsilon_{t-j} \varepsilon'_{t-j-r} \right) \quad (r = s - j)$$

$$= \text{tr} \left( \sum_{r=1}^{\infty} f^{hr}(L) \varepsilon_t \varepsilon'_{t-r} \right).$$
where \( f^{hr}(L) = \sum_{j=0}^{\infty} f^{hr}_j L^j \) with \( f^{hr}_j = (A^2_{j+r-h})'A^1_j + (A^1_{j+r})'A^2_{j-h} \). Therefore, we may express \( y_t \Delta x_{t-h} \) as
\[
y_t \Delta x_{t-h} = \text{tr} \left( f^{h0}(L)\varepsilon_t\varepsilon_t' + \sum_{r=1}^{\infty} f^{hr}(L)\varepsilon_t\varepsilon_{t-r}' \right).
\]

Apply the B/N decomposition (Phillips and Solo (1992)) to \( f^{hr}(L) \) and rewrite it as
\[
f^{hr}(L) = f^{hr}(1) - (1 - L)f^{hr}(L), \quad r = 0, 1, \ldots,
\]
with \( f^{hr}(L) = \sum_{j=0}^{\infty} f^{hr}_j L^j \) and \( f^{hr}_j = \sum_{s=j+1}^{\infty} \sum_{r=1}^{\text{r}} [(A^2_{s+r-h})'A^1_s + (A^1_{s+r})'A^2_{s-h}] \).

It follows that
\[
\frac{1}{\sqrt{n}} \sum_{t=1}^{n} y_t \Delta x_{t-h} = \text{tr} \left( f^{h0}(1) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} \varepsilon_t\varepsilon_t' + \sum_{r=1}^{\infty} f^{hr}(1) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} \varepsilon_t\varepsilon_{t-r}' \right) + r_{nh}, \quad (58)
\]
where
\[
r_{nh} = \frac{1}{\sqrt{n}} \text{tr} \left( f^{h0}(L)(\varepsilon_0\varepsilon_0' - \varepsilon_n\varepsilon_n') \right) + \frac{1}{\sqrt{n}} \text{tr} \left( \sum_{r=1}^{\infty} f^{hr}(L)(\varepsilon_0\varepsilon_{r}' - \varepsilon_n\varepsilon_{n-r}') \right).
\]

From Lemma 12, we have
\[
E|r_{nh}|^2 \leq C n^{-1}, \quad h = 1, \ldots, n - 1. \quad (59)
\]

Furthermore, observe that
\[
E y_t \Delta x_{t-h} = E \left( \sum_{j=0}^{\infty} \sum_{k=0}^{r} A^1_j \varepsilon_{t-j}\varepsilon_{t-k-h}' A^2_k \right)
\]
\[
= \sum_{j=0}^{\infty} A^1_j (A^2_{j-h})' = \text{tr} \left( \sum_{j=0}^{\infty} (A^2_{j-h})' A^1_j \right) = \text{tr} \left( f^{h0}(1) \right).
\]

In conjunction with (58), it follows that
\[
\frac{1}{\sqrt{n}} \sum_{t=1}^{n} (y_t \Delta x_{t-h} - E y_t \Delta x_{t-h})
\]
\[
= \text{tr} \left( f^{h0}(1) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} (\varepsilon_t\varepsilon_t' - I_2) + \sum_{r=1}^{\infty} f^{hr}(1) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} \varepsilon_t\varepsilon_{t-r}' \right) + r_{nh},
\]

and hence
\[
\frac{1}{\sqrt{m}} \sum_{h=1}^{n-1} k \left( \frac{h-1}{m} \right) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} (y_t \Delta x_{t-h} - E y_t \Delta x_{t-h}) = I + II + III, \quad 39
\]
where $III = m^{-1/2} \sum_{h=1}^{n-1} k((h - 1)/m)r_{nh}$ and

$$
I = \frac{1}{\sqrt{m}} \sum_{h=1}^{n-1} k \left( \frac{h - 1}{m} \right) \text{tr} \left( f^{h_0}(1) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} (\varepsilon_t \varepsilon'_t - I_2) \right)
$$

$$
= \text{tr} \left( \frac{1}{\sqrt{n}} \sum_{t=1}^{n} (\varepsilon_t \varepsilon'_t - I_2) \frac{1}{\sqrt{m}} \sum_{h=1}^{m} k \left( \frac{h - 1}{m} \right) f^{h_0}(1) \right)
$$

$$
II = \frac{1}{\sqrt{m}} \sum_{h=1}^{n-1} k \left( \frac{h - 1}{m} \right) \text{tr} \left( \sum_{r=1}^{\infty} f^{hr}(1) \frac{1}{\sqrt{n}} \sum_{t=1}^{n} \varepsilon_t \varepsilon'_{t-r} \right)
$$

$$
= \sum_{t=1}^{n} Z_t, \quad Z_t = n^{-1/2} m^{-1/2} \sum_{h=1}^{n-1} k \left( \frac{h - 1}{m} \right) \sum_{r=1}^{\infty} \varepsilon'_{t-r} f^{hr}(1) \varepsilon_t.
$$

From (59) and Minkowski’s inequality, we have $E(III)^2 = O(m^{-1}n^{-1}(\sum_{h=1}^{n-1} |k(h/m)|)^2) = O(mn^{-1})$. For $I$, first observe that, since $A_j \equiv 0$ for $j < 0$,

$$
||f^{h_0}(1)|| = \left\| \sum_{j=0}^{\infty} (A_{j-h}^2)'A_j \right\| = \left\| \sum_{j=h}^{\infty} (A_{j-h}^2)'A_j \right\|
$$

$$
\leq \sup_s ||A_s|| \sum_{j=h}^{\infty} ||A_j|| \leq C h^{-\delta} \sum_{j=h}^{\infty} j^\delta ||A_j|| \leq C h^{-\delta}, \quad h = 1, \ldots, n - 1.
$$

Therefore, $||m^{-1/2} \sum_{h=1}^{n-1} k((h - 1)/m)f^{h_0}(1)|| \leq C m^{-1/2}$, and it follows that $E(I)^2 = O(m^{-1})$, giving the stated result. ■

**Lemma 14** For $W_{\tilde{m}}(\lambda) = (2\pi\tilde{m})^{-1}[\sin^2(\tilde{m}\lambda/2)/\sin^2(\lambda/2)]$, there exist $D \in (0, 1)$ and $\kappa > 0$ such that

(a) $\int_{-D\pi}^{D\pi} W_{\tilde{m}}(\lambda) \lambda^2 d\lambda \geq \kappa \tilde{m}^{-1}$,  

(b) $\sup_{\lambda \in [-\pi, \pi]} |W_{\tilde{m}}(\lambda)| \lambda^2 \leq C \tilde{m}^{-1}$.

**Proof** We can find a constant $c \in (0, 1)$ such that, for $\lambda \in [-\pi, \pi]$,

$$
c(\lambda/2)^2 \leq \sin^2(\lambda/2) \leq (\lambda/2)^2.
$$

Therefore, there exists $\kappa > 0$ such that

$$
\int_{-D\pi}^{D\pi} W_{\tilde{m}}(\lambda) \lambda^2 d\lambda \geq C \tilde{m}^{-1} \int_{-D\pi}^{D\pi} \sin^2(\tilde{m}\lambda/2)d\lambda
$$

$$
= 2C \tilde{m}^{-2} \int_{-\tilde{m}D\pi/2}^{\tilde{m}D\pi/2} \sin^2(\theta)d\theta \geq 2C \tilde{m}^{-2}[\tilde{m}D] \int_{-\pi/2}^{\pi/2} \sin^2(\theta)d\theta
$$

$$
\sim 2CD\tilde{m}^{-1} \int_{-\pi/2}^{\pi/2} \sin^2(\theta)d\theta \geq \kappa \tilde{m}^{-1},
$$

giving part (a). Part (b) follows from (60) and $|\sin x| \leq 1$. ■

The table shows rejection rates for a 5% test using $t_\lambda$ under both the null (Column 4) and the alternative hypothesis (Columns 5-9). The two forms of the alternative hypothesis shown in Panels A and B match those in tables 5 and 6 respectively. Column 3 gives the kernel choice for $k(x)$ in (11), with PZ, QZ, and NW denoting the Parzen, Quadratic Spectral and Newey-West (Bartlett) kernels respectively. $x_t$ is specified by (18) with $\rho_1$ given by (20), with local-to-unity parameter $c$. Details are given in the text.

Entries show results from a regression of $y_{t+k} = r_{t+1} + \ldots + r_{t+k}$ on $x_t = \bar{t}$ or $x_t = d_t - p_t$. Regressions are estimated by OLS with HAC standard errors for $k > 1$, using the Bartlett (Newey-West) kernel with bandwidth set to $k - 1$. $p - V_{sup}$ is the two-sided p-value from the Valkanov (2003) sup-bound test.
Table 11: Confidence intervals on largest roots and residual correlation

\[ x_t = \mu + \varepsilon_t \]
\[ y_t = \beta_0 + \beta_1 x_{t-1} + \varepsilon_{1t} \]
\[ (1 - \alpha L)b(L)\varepsilon_t = \varepsilon_{2t} \]
\[ \delta = \text{corr}(\varepsilon_{1t}, \varepsilon_{2t}) \]

<table>

<td>(0.9733, 1.005) -0.1890</td>
<td>(0.9871, 1.007) -0.9732</td>
</tr>
</tbody>
</table>

Confidence intervals on the largest root are based on Stock (1991) using the Ng and Perron (2001) MIC criteria to select lag-length with a maximum of six lags.

Standard normal critical values apply. $t_\lambda$ is the test statistic and $m^*$ is the optimal bandwidth. The estimation and bandwidth procedures are described in detail in the text.
