Transition matrix for a bivariate normal distribution in Stata

Marco Savegnago
Bank of Italy
Rome, Italy
marco.savegnago@bancaditalia.it

Abstract. `trabinor` calculates the population transition matrix between two discretized variables when the original continuous variables follow a bivariate normal distribution. The user can specify the five parameters of bivariate normal and how to discretize the two variables by choosing either a given number of quantiles or a set of absolute boundaries.

Keywords: `st0392`, `trabinor`, transition matrix, bivariate normal, `binormal()`

1 Introduction

A transition matrix is a useful tool to describe a stochastic process that involves a finite number of states. Examples include transitions among employment statuses (unemployed, employed part-time, and full-time) for a population of workers or among rating classes for companies and governments. Often the variable of interest is continuous, such as income; for instance, one might be interested in the association between an individual's income and the income of his or her father. After a proper discretization in a finite number of classes, a transition matrix can help answer questions like the following: given that the father earns less than x , what is the probability that a child earns more than y (that is, undergoes upward mobility) or less than x itself (that is, falls into a “poverty trap”)?

`trabinor` calculates the transition matrix between two variables (after being appropriately discretized) if they follow a bivariate normal distribution. It can be used mostly for the following two purposes:

- It can be used when sample size is too small to have a reliable estimate of the transition matrix, especially when there are many cells to estimate. If one is willing to assume that the two variables are jointly normal, then sample moments can be computed from data and passed to `trabinor`.

- It can be used in Monte Carlo simulations to study the properties of estimators related to a transition matrix. For example, in intergenerational mobility analysis, the trace of a matrix (that is, the sum of the elements of the main diagonal in a square matrix) is an important summary measure of persistence of socioeconomic status¹ (for a recent survey, see Black and Devereux [2011]). The behavior of this type of estimator when variables are contaminated by measurement errors is studied in O’Neill, Sweetman, and Van de gaer (2007). `trabinor` can be used to compute the “true” (that is, population) value of such estimators under different parameter values.

2 Statistical background

Assume that

$$\begin{bmatrix} Y \\ X \end{bmatrix} \sim \mathcal{N} \left[\begin{pmatrix} \mu_Y \\ \mu_X \end{pmatrix}, \begin{pmatrix} \sigma_Y^2 & \rho\sigma_Y\sigma_X \\ \rho\sigma_Y\sigma_X & \sigma_X^2 \end{pmatrix} \right]$$

where the parameters $(\mu_Y, \sigma_Y, \mu_X, \sigma_X, \rho)$ are known or can be estimated from data.

Let $F_{Y,X}(y, x)$ also denote the joint normal cumulative distribution function (CDF), where $F_Y(\cdot)$ and $F_X(\cdot)$ are the marginal CDF. Assume that Y and X are discretized according to the rules $(-\infty < Y \leq y_1, y_1 < Y \leq y_2, \dots, y_{K-1} < Y \leq y_K, y_K < Y < \infty)$ and $(-\infty < X \leq x_1, x_1 < X \leq x_2, \dots, x_{J-1} < X \leq x_J, x_J < X < \infty)$.

Let \mathbf{M} be the transition matrix between the discretized versions of Y and X ,

$$\mathbf{M}_{J+1, K+1} = \begin{pmatrix} p_{1,1} & p_{1,2} & \cdots & p_{1,K+1} \\ p_{2,1} & p_{2,2} & \cdots & p_{2,K+1} \\ \vdots & \vdots & \ddots & \vdots \\ p_{J+1,1} & p_{J+1,2} & \cdots & p_{J+1,K+1} \end{pmatrix}$$

where the generic element p_{jk} gives the probability that Y falls in the k th class given that X falls in the j th class.

$$\begin{aligned} p_{jk} &= \Pr(y_{k-1} < Y < y_k \mid x_{j-1} < X < x_j) \\ &= \frac{\Pr(y_{k-1} < Y < y_k, x_{j-1} < X < x_j)}{\Pr(x_{j-1} < X < x_j)} \\ &= \frac{F_{Y,X}(y_k, x_j) + F_{Y,X}(y_{k-1}, x_{j-1}) - F_{Y,X}(y_k, x_{j-1}) - F_{Y,X}(y_{k-1}, x_j)}{F_X(x_j) - F_X(x_{j-1})} \end{aligned}$$

The last equality exploits the Stata functions `binormal(h , k , r)` (for the numerator) and `normal(z)` (for the denominator).

1. The higher the trace, the higher the elements on the first diagonal and the stronger the association between a father’s and a son’s socioeconomic statuses.

3 The trabinor command

3.1 Description

Besides the five parameters of the bivariate normal distribution $(\mu_Y, \sigma_Y, \mu_X, \sigma_X, \rho)$,² Y and X can be discretized by choosing either a given number of quantiles or a set of absolute boundaries. If the user sets a number Q of quantiles, then the resulting transition matrix will obviously be of size $Q \times Q$. If the user sets K absolute boundaries for Y and J absolute boundaries for X , then the resulting transition matrix will be rectangular of size $(J+1) \times (K+1)$.³ In this case, boundaries for X must be chosen such that all the states of X have a nonzero probability of occurrence; otherwise, we will be conditioning on an impossible event.⁴ A warning message appears if any of the marginal probabilities of (the discretized) X are smaller than $5,000,000^{-1}$; a second message appears if this probability is so small that the corresponding row of the transition matrix cannot be computed.

If neither the number of quantiles nor the absolute boundaries are specified, the `trabinor` command computes a 5×5 quantile matrix by default.

Results are displayed in percentage points, so the row sums of the transition matrix sum to 100.

3.2 Syntax

The syntax of `trabinor` is the following:

```
trabinor [ , quant(#) y(numlist) x(numlist) muy(#) sy(#) mux(#) sx(#)
          rho(#) format(string) ]
```

3.3 Options

`quant`(#) specifies in how many quantiles Y and X should be divided. The default is `quant(5)`. `quant`(#) must be an integer greater than 1 and cannot be combined with the options `y`() and `x`() .

`y`(numlist) sets the boundaries of the marginal distribution of Y . It cannot be combined with `quant`() .

2. The default values are those of a standard bivariate normal with $\rho = 0.5$.

3. To see this, imagine that we set the boundary 0 for both Y and X ; then, both variables will be divided in two levels, namely, $(-\infty, 0)$ and $(0, \infty)$.

4. From a theoretical point of view, the normal distribution assigns a nonzero probability on any interval defined on the real line, but these probabilities can be very small. For example, if $\Phi(\cdot)$ denotes the standard normal CDF, then $\Phi(-5) \approx 0.00000028665 < 3,000,000^{-1}$. Therefore, a wrong choice of the boundaries might induce some issue of numerical approximation, given that the conditional probabilities are computed as the ratios between the joint and marginal probabilities.

`x(numlist)` sets the boundaries of the marginal distribution of X . It cannot be combined with `quant()`.

If none of the options `quant()`, `y()`, or `x()` are specified, `trabinor` computes a 5×5 quantile transition matrix (as if `quant(5)` were invoked). If only `y()` is specified, the same boundaries are applied to X ; analogously, if only `x()` is specified, the same boundaries are applied to Y .

`muy(#)` defines the mean of Y . The default is `muy(0)`.

`sy(#)` defines the standard deviation of Y . The default is `sy(1)`.

`mux(#)` defines the mean of X . The default is `mux(0)`.

`sx(#)` defines the standard deviation of X . The default is `sx(1)`.

`rho(#)` defines the correlation coefficient between Y and X . The default is `rho(.5)`.

This must be between -1 and 1 .

`format(string)` controls how to display results. The default is `format(%9.3f)`.

3.4 Stored results

`trabinor` stores the following in `r()`:

Scalars

<code>r(muy)</code>	mean of Y	<code>r(sy)</code>	standard deviation of Y
<code>r(mux)</code>	mean of X	<code>r(sx)</code>	standard deviation of X
<code>r(rho)</code>	correlation coefficient between Y and X		

Matrices

<code>r(M)</code>	resulting transition matrix	<code>r(chk100)</code>	consistency check on <code>r(M)</code> (that is, row sums are equal to 100)
<code>r(PY)</code>	matrix of marginal probabilities of Y	<code>r(J)</code>	matrix of joint probabilities
<code>r(PX)</code>	matrix of marginal probabilities of X		

4 Examples

Here I discuss three examples of `trabinor`. Let Θ_1 , Θ_2 , and Θ_3 represent the five parameters of the bivariate normal distribution in each of the three examples.

In the first example, `trabinor` computes the quantile transition matrix of size 4 for a bivariate standard normal distribution with $\rho = 0.5$. Moreover, it uses the output program to obtain the trace of the transition matrix. Interpreting the results for the quantile transition matrix is straightforward: the probability that Y is smaller than its first quartile, given that X is smaller than its first quartile, is 48.1%. Analogously, using a formal notation, $\Pr\{F_Y^{-1}(0.50) < Y \leq F_Y^{-1}(0.75) \mid X \leq F_X^{-1}(0.25); \Theta_1\} = 16.8\%$, and so on.

```

x4   7.2  16.8  27.8  48.1
-----

. scalar mytrace = trace(r(M))
. display mytrace
155.32692
```

In the second example, let's specify different parameters for the bivariate distribution. The variable X is discretized in 4 classes $[(-\infty, -3], (-3, 0], (0, 3], (3, \infty)]$ and Y in 6 classes $[(-\infty, 2], (2, 3], (3, 5], (5, 7.5], (7.5, 10], (10, \infty)]$. From the output, we observe that $\Pr(Y < 2 \mid X < -3; \Theta_2) = 0.4\%$, or that $\Pr(7.5 \leq Y < 10 \mid -3 \leq X < 0; \Theta_2) = 23.0\%$, and so on. We then look at the marginal probabilities for both variables, presented as row vectors: $\Pr(7.5 \leq Y < 10; \Theta_2) = 15.5\%$ and $\Pr(-3 \leq X < 0; \Theta_2) = 43.3\%$.

```

In the last example, we pass the empirical sample moments to `trabinor` using a dataset containing measures of blood pressure in 2 time periods (`bp_before` and `bp_after`) for a sample of 120 patients characterized by high blood pressure. Then, we look at the conditional probability of being in hypertension (`bp_after` ≥ 140) given the level of `bp_before`. We note that this conditional probability is 80% given hypertension in the past and 69% given no hypertension in the past.

```
