Abstract

[This study presents the author's estimates of producer and consumer subsidy equivalents (PSE's and CSE's) for Yugoslavia and Poland and uses the Static World Policy Simulation (SWOPSIM) framework developed at ERS to model the effects of trade liberalization (equated here with domestic policy reform) on agricultural production and trade in those two countries.] PSE and CSE calculations for 1986, the base year used in the model, show that in that year both Yugoslavia and Poland subsidized producers on a level roughly equal to that in Western Europe. On the other hand, Poland also subsidized consumers quite heavily, while Yugoslavia taxed its consumers, generally to a greater extent than in Western Europe. SWOPSIM results suggest that the ongoing economic reforms in these countries, if successful, could dramatically alter current patterns of production and trade in both countries. Poland could become a significant net agricultural exporter, mainly the result of a large increase in pork exports. Yugoslavia could shift to a net importer of grains, but increased exports of meat and other products could bring it close to self-sufficiency in agricultural trade.

Keywords: Eastern Europe, Yugoslavia, Poland, trade liberalization, producer subsidy equivalents, consumer subsidy equivalents, SWOPSIM, agricultural trade, agricultural policy, economic reforms

Acknowledgments

The author owes special gratitude to Robert Koopman for his help in obtaining and interpreting the model results, his advice in estimating the producer and consumer subsidies, and useful comments on the manuscript. Special thanks also go to Marvin Jackson of Arizona State University. He spent fiscal 1989 in Eastern Europe on a cooperative agreement with the Economic Research Service and sent back data and other information that have been useful in this research. The author also wishes to acknowledge Elizabeth Kirkwood and Julie Linkins, who compiled much of the price and budget data used in this research, and Roger Spindler for his help in preparing the final tables.

Trade Liberalization in Yugoslavia and Poland

Nancy J. Cochrane

Introduction

The question of the liberalization of world agricultural trade is an important item on the agenda of the latest round of multilateral trade negotiations begun in 1986 by the members of the General Agreement on Tariffs and Trade (GATT). These negotiations, known as the Uruguay Round, were the result of a growing recognition that a major cause of the falling commodity prices and stagnant world trade of the 1980's has been the complex array of interventionist agricultural policies pursued by the trading countries. These policies include tariff and nontariff trade barriers, price supports, and a variety of producer and consumer subsidies, all of which have insulated domestic markets from world market fluctuations. A major goal of the Uruguay Round has been an agreement on a multilateral reduction or elimination of these barriers.

This paper will analyze the possible effects of trade liberalization in Yugoslavia and Poland. Work in progress includes Hungary and Czechoslovakia, as well. Eastern Europe is of interest for several reasons. Five of the countries--Yugoslavia, Czechoslovakia, Poland, Hungary, and Romania--are members of GATT. Of the remaining three, only Albania still has no interest in GATT membership. Bulgaria has observer status and is seeking full membership and, with a new government in place, prospects for its membership should be improved. To date, there has been little discussion of GATT membership in the German Democratic Republic, but given the probability of eventual German reunification, this could cease to be an issue. In addition, most of the countries have seen their net exports of livestock products fall as a result of European Community (EC) import barriers and low world prices. Most of these countries have a strong interest in any negotiations that might result in the reduction or elimination of EC import barriers. East European livestock exports would also benefit from the increase in world prices that trade liberalization in the West is expected to produce.

Most important, all the countries (except Albania) are seriously pursuing some degree of market-type reforms. To varying degrees, all are attempting to reduce producer and consumer subsidies and align domestic prices with world levels. Yugoslavia and Poland have taken the most radical steps toward those goals. Both are suffering severe economic dislocations, which could result in a fall in agricultural output, particularly in Poland. However, the current situation should be viewed as the short-term result of these reforms. The key question to be addressed in this study is the longer term changes in agricultural production and trade which might be expected if the short-term

disruptions are effectively ironed out. Because the focus of this study is on the effects of policy reform in these two countries, it was assumed no liberalization occurred in the other regions of the world.

The policy reforms modeled in this study include the elimination of all price controls, an exchange rate set by the market, and the removal of all barriers to the free entry of imports. However, it seems highly unrealistic to assume that the governments of these countries could force producers and consumers to face world market prices without addressing the serious systemic problems which hamper productivity growth (the distorted input market, the monopsonistic purchasing system, the outdated infrastructure, and inadequate capital markets). Therefore, it was assumed that price reform would be accompanied by increases in productivity which could result from the resolution of these other problems. The results indicate that, for certain commodities, there will be increases in production and net exports despite a general decline in prices paid to producers.

Background

The current situation in both Yugoslavia and Poland can be viewed as the short-term result of the removal of subsidies and price controls. Both experienced high inflation in 1989 and, while both have now managed to bring their inflation to a halt, both are experiencing a fall in real incomes and a resulting drop in consumer demand. Furthermore, farmers in both countries are caught in a classic price scissors. The farmers are experiencing rising input prices, while lagging consumer demand holds down procurement prices. Poland is likely to see a fall in output in 1990. Yugoslavia will probably see some increase over 1988 and 1989, but only because of especially bad weather in those 2 previous years.

In both countries, many of the institutional barriers which insulate farmers from market forces and hamper productivity gains remain in place. Agriculture is dominated by small, fragmented private farms. Farms average 5 hectares in Poland and only 2.5 in Yugoslavia. Purchasing has traditionally been in the hands of state-owned food processing monopolies in Poland and large, vertically integrated, socialized kombinats in Yugoslavia. Both types of purchasing organizations have enjoyed monopsonistic power over the farmers. While there are reports in both countries of the emergence of private competition to these organizations, this has not yet occurred on a large scale. Furthermore, the production and supply of inputs is still in the hands of socialized monopolies, with the result that farmers still face high prices, limited supplies, and an inappropriate assortment of inputs. In both countries, recent policy has aimed at improving conditions for the private farmers and removing these barriers to productivity growth. But the success of such measures can be evaluated only after a longer period of time.

As long as these barriers are in place, the ultimate effect of removal of all support to producers will be a large drop in producer prices, which will lead to sharp declines in production and possibly a significant exodus off the farms into the cities. A more realistic long-term scenario would include both producer price reform and simultaneous economywide reforms which eliminate the systemic constraints of central planning and lead to productivity gains. With the productivity increases that might occur following effective reform, farmers could well find that they could achieve greater profits even with lower producer prices. Economywide reform could still result in the exit of a

significant number of farmers, as market forces will probably encourage the consolidation of farms and the retirement of some of the smaller farmers. However, under the current system of distorted input and output prices, the extent and pattern of exit could be wrong, with some of the more efficient farmers being forced out.

This study models this complete reform scenario. The model was thus designed to simulate the combined effects of the removal of all price support (or controls) and the productivity gains that could result from economywide reform.

The Model

The model used to test the effects of trade liberalization was built using the Economic Research Service SWOPSIM (Static World Policy SIMulation) modelling framework.¹ This is a spreadsheet-based framework used to create a static, global, net trade model for agriculture. It consists of a set of constant elasticity supply and demand equations that use synthetic own- and cross-price elasticities. For each country i and commodity j , supply and demand are generally defined as:

$$\begin{aligned} S_{ij} &= g_{ij}(PP_{ij}, PP_{ik}) \\ D_{ij} &= f_{ij}(PC_{ij}, PC_{ik}) \end{aligned}$$

where PP and PC are the domestic prices faced by producers and consumers, respectively. P_{ik} represents relevant cross-product prices. The domestic producer and consumer prices which are entered into the model (PP and PC) are calculated as the sum of the market price and per unit subsidies (discussed in detail below). That is:

$$PP_{ij} = TRDVAL + PPW_{ij} - PMRG_{ij} + (PW_j * XR)^{PTE_{ij}}$$

where:

- TRDVAL = the value of the domestic commodity on world markets
- PW_j = change in world price for commodity j
- PTE_{ij} = price transmission elasticity
- XR = exchange rate
- PPW_{ij} = producer price wedge in country i for commodity j
- $PMRG_{ij}$ = producer price margin that reflects any difference between PP_{ij} and PW_j not captured by the price wedge

Similarly,

$$PC_{ij} = TRDVAL + CPW_{ij} - CMRG_{ij} + (PW_j * XR)^{PTE_{ij}}$$

where:

- CPW_{ij} = consumer price wedge in country i for commodity j

¹This model was first described in Vernon O. Roningen and Praveen Dixit, A Static World Policy Simulation (SWOPSIM) Modeling Framework, Staff Report AGES860625, U.S. Dept. Agr., Econ. Res. Serv., 1986.

CMRG_{ij} = consumer price margin that reflects any difference
between PC_{ij} and PW_j not captured by the price
wedge

Net trade is calculated as the difference between supply and demand:

$$T_{ij} = S_{ij} - D_{ij}$$

The model's world market-clearing condition is that world net trade for each commodity equals zero. All the supply and demand equations are initialized on base year price and quantity data; for this study the base year is 1986. That is, given the elasticity matrices, equations are fit to pass through the base year price and quantity data. The model solves for a new equilibrium only after receiving a shock to the base year equilibrium. This shock could consist of a price change, a demand or supply shift, or a combination of the two. The model solution represents an equilibrium that might be expected about 6 years after the shocks are implemented, assuming no other changes occur.

The SWOPSIM framework is designed to ensure that own- and cross-price elasticities are selected in conformance with symmetry conditions and multi-output production theory constraints for joint products and input/output relationships. These constraints are important in the dairy sector, where butter and skim milk are joint products produced from fluid milk and cheese is another product that depends on raw milk as an input. The soybean complex is another area where such joint product relationships must be taken into account.² The feed-demand equations include the quantity supplied of relevant livestock products and are derived from historical feed shares, which enter the cross-price elasticity calculations. These feed shares can be altered to reflect the improved feeding efficiency that might occur under a reform scenario. The own- and cross-price elasticities used in the model are in tables 1 and 2.

In using SWOPSIM to simulate the domestic reform in Poland and Yugoslavia, this author imposed two shocks: the removal of the wedges between domestic producer and consumer prices and world market prices and an outward shift of the supply curve to simulate the productivity gains that might be expected.

Applying SWOPSIM to a Centrally Planned Economy

The model assumes perfectly competitive world markets: that price is the sole determinant of trade, all countries are price takers, and all markets clear. One could question the applicability of some of these assumptions to the centrally planned economies of Eastern Europe, particularly in Poland which, in 1986, was characterized by disequilibrium in several markets. However, there is convincing evidence that the foreign trade decisions made by central planners were price driven. Previous work by this author shows Polish and

Yugoslav import demand to be elastic.³ Furthermore, there is ample evidence that Polish and Yugoslav farmers, being largely private, make planting decisions in response to movements in relative prices.

Also, being a partial equilibrium model, the model does not incorporate all of the potentially important cross-sectoral effects of reform. The model implicitly assumes that any changes in resource use entailed by agricultural reform are unconstrained (that is, perfectly elastic). The assumption of perfectly elastic input markets could be a serious problem in the case of Poland, since the bottlenecks in Polish input supplies are notorious. While Yugoslavia is not characterized so much by input shortages, the supply is also controlled by a monopoly which maintains higher-than-world prices. The incorporation of supply shifts into the model was an attempt to address that shortcoming (more discussion below). Given the relatively large share of the agricultural sector in these countries' GDP's, capturing the cross effects with other sectors of the economy would be useful, but these effects are not examined in this study.

Producer and Consumer Subsidies in Yugoslav and Polish Agriculture

The support measures, or price wedges, entered into the model consist of producer and consumer subsidy equivalents (PSE's and CSE's) calculated for each commodity. The PSE is defined as the "level of subsidy that would be necessary to compensate producers (in terms of income) for the removal of government programs affecting that commodity."⁴ The CSE is defined analogously as the level of subsidy needed to compensate consumers for the removal of government programs. PSE's and CSE's can be either positive or negative. A positive PSE/CSE constitutes a subsidy, while a negative PSE/CSE is a tax. The PSE/CSE framework is under consideration for use by negotiators in the Uruguay Round because it provides a single measure of all government policies affecting a given commodity and enables negotiators to make fairly meaningful cross-country comparisons of government support provided to agriculture.

³Nancy J. Cochrane, Hard Currency Constraints and East European Grain Imports, Staff Report AGES880125, U.S. Dept. Agr., Econ. Res. Serv., 1988. Some of the demand elasticities entered into SWOPSIM for the current study were derived from the import demand elasticities estimated in the referenced report. These elasticities, however, represent the planners' demand curve, and it is quite likely that the actual consumers' demand curve is more elastic than the planners'. There have been attempts to estimate the true consumers' demand functions: Josef Brada and Arthur King, "A Disequilibrium Approach to Modelling Foreign Trade in Centrally Planned Economies," Ch. 11 in Christopher Davis and Wojciech Charemza, eds., Disequilibrium and Shortage in Centrally Planned Economies, London: Chapman-Hall, 1989. Koopman, Cook, and Liefert in a forthcoming ERS Staff Report estimate the true consumers' demand function for the USSR for use in SWOPSIM. Future work on Poland will experiment with different elasticities, but for this work, consumer demand elasticities were based on the planners' demand curve.

⁴See Government Intervention in Agriculture: Measurement, Evaluation, and Implications for Trade Negotiations. FAER-229, U.S. Dept. Agr., Econ. Res. Serv., 1987.

The PSE's and CSE's described below are measures of the policies which were in effect in 1986, the base year of the model. As of 1990, many of these policies have been liberalized or dismantled. In 1986, producer subsidies fell into four basic categories: procurement policies, border intervention measures, input subsidies, and other services paid from the State budget. Consumer subsidies included border intervention measures and payments from the budget to food processors to cover the gap between the relatively high prices they had to pay to agricultural producers and the low wholesale prices they were allowed to charge. These policies are briefly described below.

Border Intervention

In order to conserve foreign exchange, Yugoslavia and Poland had erected a variety of barriers to agricultural imports. Both countries imposed tariffs on imports, but these for the most part were not that high and did not form much of an impediment to trade. More important were the nontariff barriers that had been put in place, discussed below for each country.

Poland

In 1986, virtually all foreign trade in Poland was carried out by specialized foreign trade organizations (FTO's) under the Ministry of Foreign Trade. Each FTO specialized in one line of products--for example, all grain trade was carried out by the FTO Rolimpex--and had a monopoly over those products. Export and import volumes and foreign exchange allocations were subject to central planning. With the reforms that began in the early 1980's, an increasing number of production enterprises were licensed to engage directly in foreign trade without going through an FTO. Furthermore, most exporters were allowed to retain a certain portion of their foreign exchange earnings, which they could use to import anything they needed. However, most agricultural commodities were identified as basic or strategic, so agricultural trade was still being carried out by a handful of FTO's, and most were still subject to central planning.

Yugoslavia

Most trade in Yugoslavia was also carried out by FTO's, but there were hundreds of such organizations, and they competed openly with each other. Nevertheless, there were a number of tariff and nontariff barriers which prevented the free flow of trade. Tariffs on agricultural goods were usually 5-15 percent, but imports were also subject to a variety of "equalization taxes" (intended to offset the difference between border and domestic prices) and other charges. Total charges typically came to 30-40 percent and posed a significant obstacle to imports.

But the nontariff barriers were at least equally important. Many imports, and particularly agricultural imports, were subject to varying degrees of restrictions or quota. According to the foreign exchange legislation passed in 1986, imported commodities were classified by four categories:

Free. These commodities could be imported with no restrictions. An enterprise could purchase as much foreign exchange as it wanted for these imports, limited only by the foreign exchange reserves of the central bank and the firm's dinar reserves.

Conditionally free. For these commodities, foreign exchange was allocated according to enterprises' import rights, which were awarded on the basis of either need or the previous year's export performance.

Under quota. Physical quotas were set by the federal government and allocated among firms desiring to import.

Under license. This system covered only a few products, such as sugar, cocoa, coffee, and narcotics, which were covered by international agreements.

The mechanism used to administer the quota was government allocation of foreign exchange. The Foreign Exchange Legislation of 1986 required exporters to turn over foreign exchange receipts to the central bank in exchange for dinars. In turn, would-be importers had to apply for an allocation of foreign exchange, which was determined in accordance with the above conditions. The exchange rate was set by the government, but the government at that time kept the rate relatively close to the market-clearing rate (as evidenced by the small premium in the black market) through continual devaluations of the dinar.

In 1986, most raw agricultural products were under quota. Since that year, more and more products have been shifted into the free category. The hope of the authorities was that a realistic exchange rate would be sufficient to keep imports under control. In fact, by 1989, one of the strongest factors holding back imports was the poor dinar liquidity of most enterprises, not government limits on foreign exchange.

With the reforms introduced at the beginning of 1990, the Yugoslav Government issued a new, fully convertible, dinar pegged at 7 dinars to the Deutsche mark, freed up most prices, and eliminated most nontariff barriers to imports. Even so, all bulk commodities except oilseeds remained under quota in 1990.

Procurement Policies

Overall, the effect of the border measures in both Yugoslavia and Poland was to restrict imports, thus constraining the domestic supply and keeping producer prices above world market prices. However, procurement policies in effect in both countries in 1986 tended to dampen that upward pressure on producer prices. These procurement policies tended to hold producer prices below the level that would have been set by the domestic market given the existing border measures.

Poland

Prices paid to agricultural producers were for the most part fixed by the government, and most production sold by both private and socialized producers was purchased by state organizations at these state-set prices. Throughout most of Poland's postwar history, these procurement prices were set very low, generally far below world levels. During the 1980's, however, in attempts to raise profitability for producers, the government granted large nominal increases in procurement prices, such that by 1986, most prices were well above world levels. Nevertheless, producers felt they were being taxed. Procurement was almost entirely in the hands of a limited number of state-run food processing monopolies, which took advantage of their monopsonistic relationship to the farmers and kept state procurement prices below the prices

prevailing on the small domestic, free market. Furthermore, Poland's government had allowed prices of industrial inputs to rise faster than agricultural commodities, and in many cases official producer prices were not sufficient to cover the escalating production costs facing farmers.

Yugoslavia

Although Yugoslavia's system of socially owned, worker-managed enterprises was quite different from the state-run enterprises of Poland, the effect of Yugoslavia's procurement system on producer prices was the same as in Poland. Purchasing in Yugoslavia was largely in the hands of some 2,000 vertically integrated, socialized kombinats. These kombinats were involved in every stage of food production from crop and livestock production to processing to distribution and retailing. However, despite the large number of these organizations, there was little competition among them. Barriers to the entry of new firms were formidable, and the existing kombinats had effectively divided up the territory in Yugoslavia such that for the most part there was only one operating in any given region.⁵ Farmers usually found there was only one organization to which they can sell; they could sell outside their immediate area only with the permission of the organization operating in that area.⁶

The Yugoslav Government set minimum, or protective prices, for most agricultural commodities, and the republic governments often guaranteed premia over and above those minimum prices. The actual prices paid to the farmers were negotiated with the purchasing organization and often rose above the protective prices. However, because of the monopsonistic nature of the purchasing system, these prices tended not to rise to the levels that they would have had there been competition.

In both Poland and Yugoslavia, there was a domestic, free market for agricultural commodities, where farmers could sell their output directly at market-set prices, which were usually higher than the prices paid by the socialized purchasing organizations. However, the amounts traded at free-market prices were very small. There were two main reasons for the small volume of free-market sales. For one thing, Polish and Yugoslav farmers, although mainly private, were given very strong inducements to sell to the State purchasing organizations. Access to inputs and credit was very often limited to those farmers who signed delivery contracts with these organizations. In addition, private middlemen were illegal in both countries until 1989, so the farmers could sell only as much as they could physically transport to the market. This transport was often by horse cart. The state thereby effectively forced farmers to be both farmer and marketer if they wanted to sell on the domestic free market. Many farmers apparently did not consider the returns from free-market sales to be sufficient to cover the required marketing costs.

⁵For further discussion of this phenomenon, see Nancy J. Cochrane, "Republic and Provincial Barriers in Yugoslav Agricultural Marketing," presented at the annual meetings of the American Association for the Advancement of Slavic Studies, Honolulu, HI, Nov. 1988.

⁶Ekonomska Politika, Belgrade, Apr. 20, 1987.

Input subsidies

By 1986, in both countries, the prices of industrial inputs had risen much faster than agricultural producer prices. To partially alleviate the situation, both governments subsidized the price (themselves set to cover average production costs) of fertilizers, plant protection agents, and seed. Poland also subsidized fuel prices, while Yugoslavia reduced the taxes paid on fuel for socialized farms and private farmers who signed contracts with socialized organizations. In addition, both governments provided credit to socialized farms at interest rates below the official rate.⁷ Poland's input subsidies are detailed in table 3 (similar data are unobtainable for Yugoslavia).

Table 3--Subsidies paid from the Polish budget for agricultural inputs

Subsidy	1983	1984	1985	1986	1987

⁷During Yugoslavia's period of hyperinflation, the positive impact of these interest subsidies was virtually wiped out. Interest rates were continually adjusted in keeping with inflation, placing a heavy burden on the enterprises. The interest subsidies were periodically adjusted to reflect these rises, but did not compensate for the full rise in rates.

Consumer Subsidies

The governments of both Yugoslavia and Poland have until very recently sought to maintain low and stable food prices for the population. The Polish government maintained controls on the state retail prices of virtually all basic food commodities until August 1, 1989. Yugoslavia maintained maximum wholesale prices for a few strategic commodities until January 1990, when all controls were removed. In both countries, large subsidies were needed to ensure a profit to food processors caught between the low, state-controlled wholesale prices and the high prices paid to producers.

Poland

The Polish Government paid subsidies to processors of grain products, dairy products, meat, vegetable oil, sugar, and fish (table 4). These subsidies were not uniform across all producers of a given commodity, but were determined individually for each enterprise on the basis of its production costs. Total consumer subsidies in 1986 came to 403 billion zloty (\$2.3 billion at the official exchange rate in effect in 1986). This amount was equivalent to 16 percent of the value of food consumption in that year, excluding alcoholic beverages. These subsidies rose in real terms through 1987 (the last available year of data).

Yugoslavia

In the latter half of the 1980's, Yugoslavia was attempting to reduce controls on food, but periodically felt compelled to reinstate controls. In 1985, Yugoslavia set maximum wholesale and retail prices only for sugar, vegetable oil, wheat flour, and bread. Meat prices were liberalized in that year. In 1986, maximum prices remained in effect for only flour and vegetable oil, although enterprises wishing to raise prices for meat and sugar were supposed to provide justification before doing so. However, in 1987, in an attempt to dampen the effects of Yugoslavia's accelerating inflation, federal authorities reimposed maximum wholesale and retail prices on sugar, milk, meat, and bread.

To compensate processors for the losses entailed by these wholesale price controls, the Yugoslav Government paid subsidies to flour mills and other food processors. Information on these subsidies is very sketchy, but it appears that they were mainly in the form of low-interest loans for the purchase of raw agricultural commodities (although the interest rates were still adjusted monthly for inflation). In 1987, interest subsidies to food processors came to 55 billion dinars (\$122 million at the exchange rate in effect in that year). These subsidies were on a much smaller scale than Poland's, and the result, as will become clear in the following section, is that Yugoslav consumers paid most of the cost of the subsidies going to producers.

PSE and CSE Calculations

The methodology used to estimate Poland and Yugoslavia's PSE's and CSE's is detailed in the appendix. In brief, the effects of procurement policies and border measures were measured jointly by calculating the gap between the domestic producer or consumer price and the trade price of a given commodity. Polish input subsidies were derived from published budget data. Input subsidies for Yugoslavia were calculated from information on fertilizer subsidies provided by the U.S. Agricultural Counsellor in Belgrade. Tables 5-6 are summary tables of Yugoslav and Polish CSE's and PSE's, expressed as a percentage of the total value of consumption or production. Tables showing more detailed calculations are in the appendix.

Support to Producers

In 1986, both Yugoslavia and Poland subsidized the producers of most commodities. The exceptions were pork and dairy products in Poland, producers of which were heavily taxed in the later recent years. In all cases, the bulk of the PSE's were the result of border and procurement measures. Input subsidies for the most part did not exceed 5 percent of the value of production. The PSE's varied greatly from year to year, but this variation resulted mostly from fluctuations in world prices. Domestic prices tended to rise with the domestic inflation rate, independent of changes in world prices. While these producer subsidies seem substantial, the reader should be aware that these are on a par with many other countries. For example, in 1986 the European Community PSE for Durum wheat came to 52 percent of the value of production, which is about the same as for Poland. In the United States, this value was 63 percent in the same year; in Japan, it was 103 percent. Furthermore, subsidies paid to Polish producers did not have the same effect of stimulating supply that they do in the EC. Polish farmers had a much less favorable operating environment than EC producers, which prevented the

positive supply response that could be observed in the EC. As a result of the state monopoly on input markets, farmers in Poland faced sharply higher input prices, along with uncertain supplies. They also had to contend with a much poorer infrastructure and a government bureaucracy which had traditionally favored socialized farms.

Furthermore, the PSE's detailed here were estimated using the official exchange rate. This is a serious problem for Poland. The black market exchange rate was close to five times the official rate in 1986. If a more realistic exchange rate were used, Polish PSE's would turn out to be considerably lower, quite possibly even negative. The exchange rate is not such a serious problem for Yugoslavia. In 1986, the dinar was being rapidly devalued in line with the inflation rate, and most Yugoslav economists seem to feel that the exchange rate in that year was fairly close to a market rate.

The black market exchange rate was generally only 20-30 percent above the official.

Support to Consumers

There are two components to the CSE: the effect of border intervention measures and budgetary payments to processors. In both Yugoslavia and Poland, the effect of the border intervention policies put upward pressure on consumer prices. However, both governments paid subsidies to food processors to dampen that effect. The difference between the two countries was that Polish consumers paid below-world prices for most food items, while Yugoslav consumers remained taxed even after government subsidies.

In Poland, despite the large number of commodities which were taxed, net subsidies to consumers were positive because of the extremely large, positive subsidies to the consumption of wheat, pork, poultry, and milk. The zloty value of these subsidies was far greater than the value of the combined tax on the other commodities. It is because of the huge subsidies paid on grain

products, meat, and milk that the subsidies paid out of the Polish budget were so much greater than those in Yugoslavia.

Yugoslavia's tax on consumers tended to be higher than in most other countries. In 1986, the tax on wheat consumers, for example, came to 43 percent of the value of consumption in Yugoslavia, compared with 39 percent in the EC, 37 percent in Japan, and only 9 percent in the United States. Poland, despite the publicity given to its consumer subsidies, subsidized its consumers considerably less than the Soviet Union and in fact taxed the consumption of several commodities at rates comparable with the EC.⁸ Once again, however, these CSE's were calculated using the official exchange rate. With a more realistic exchange rate, these subsidies would have been very large, indeed.

Estimating Productivity Shifts

Initial SWOPSIM runs involved simply removing the price wedges and solving for a new equilibrium at the new, unsupported prices. However, the results showed drastic declines in production and a huge surge in imports. The reason was the assumption of no changes in input markets. Under the scenario originally tested, Polish and Yugoslav farmers were suddenly faced with sharply lower prices for their output, but were constrained by the same barriers to productivity gains that they experienced in 1986. Farmers could barely make a profit under the existing price structure; confronted with what was for some commodities a 40-percent price cut, many farmers would decrease or even halt production.

Within the SWOPSIM framework, there were two ways to simulate a more realistic scenario. One would have been to calculate the "tax" on producers that resulted from the excessive production costs incurred because of the inefficiency of the system. It is possible that this tax would have exceeded the positive subsidies, so that on net, the price wedge entered into the model would have been negative. Alternatively, a supply shifter could be entered into the model. That approach imposes an outward shift in the supply curve on the assumption that with a more rational input market and an improved infrastructure, farmers would find that they could produce more output at any given price.

The second approach was taken for this study. Table 7 shows the productivity increases assumed to be possible for each commodity. The assumption is that, after reform, wheat yields, for example, will be 20 percent higher; feeding efficiency in the hog sector will improve by 20 percent, etc.

The choice of supply shifters for the grains was based on a comparison of Polish and Yugoslav yields with selected West European yields during the 1980's. The assumption was that in the 6- to 7-year time horizon projected by the model, the removal of these barriers to productivity would enable Polish and Yugoslav farmers to close the gap between their yields and those of Western Europe by about 50 percent. A shifter was not entered for Polish corn because Poland's corn yields are already on a par with Western yields. And, because corn is a small crop in Poland, further productivity gains seemed

⁸As calculated by Koopman, Liefert, and Cook (U.S. Dept. Agr., Econ. Res. Serv.) for the Soviet Union.

Table 7--Supply shifters entered into SWOPSIM

unlikely. Likewise, no shifter was introduced for soybeans or other oilseeds on the assumption that Poland and Yugoslavia have about reached their capacity.

The productivity gains entered into the livestock sector were based on a World Bank statement that the Polish hog sector was about 30 percent less efficient than "optimal." For lack of more specific information, this statement was assumed to hold true for Yugoslavia as well. Again, it seemed unlikely that efficiency would rise completely to its optimal level in 6-7 years, so a gain of 20 percent was assumed. Because of a lack of data on either country's cattle sector, this same gain was assumed for that sector. The 30-percent gain projected for poultry was based on the assumption that productivity gains could be achieved more quickly in that sector.

Results of Trade Liberalization

The model results summarized in tables 8, 9, and 10 show the changes that can be expected to take place following reform in Yugoslavia and Poland. The changes simulated are:

- o All producer and consumer price wedges are removed and the price transmission elasticity is set to one. These changes allow full transmission of world price movements to the domestic economy.
- o Economywide reform takes place, which lowers per unit production costs and gives the impetus for significant productivity gains.

The major changes in agricultural production and trade that are projected are outlined below.

Poland

Substantial rise in pork exports. Because hog producers were taxed in 1986, trade liberalization results in a 26-percent rise in producer prices, while at the same time consumer demand is depressed by a 43-percent rise in consumer

prices. The resulting surplus is augmented further by the expected productivity increase. Thus, the model predicts substantial domestic pressures for increased pork exports.

Switch from exporter to importer of beef. The realignment of Polish beef prices leads to a fall in output and an increase in consumption. Polish cattle inventories and beef production are presently on the decline because of unfavorable price ratios. The model projects a continuation of that trend. On the consumer side, beef prices after liberalization are lower than pork prices, leading to a shift from pork to beef consumption.

Moderate increases in imports of wheat and corn. Consumer prices rise just 2 percent, while producer prices fall 56 percent. Because of the productivity shift, there is a net 5-percent increase in output, despite the substantial price drop. At the same time, there is a 6.5-percent increase in demand, mainly a result of increased feed use in the hog sector. The result is an 11-percent rise in imports.

Switch to net exporter of other coarse grains. Again, the negative effect of a 47-percent decline in rye and barley prices is offset by productivity increases, which lead to a net 17-percent rise in output. Increased feed needs generate an 11-percent increase in demand, but still leave an exportable surplus.

Increase in oilmeal imports. A 34-percent decline in the producer prices for rapeseed leads to a decline in domestic meal output. Changes in the consumer prices of oilseed meals are negligible, and the projected increases in the livestock sector generate an increased demand for both soybean and other meals. The result is an 8-percent increase in soymeal imports and a 20-percent rise in net imports of other meals.

Poland becomes a large net agricultural exporter. This status results mainly from the increase in pork exports, which more than compensates for the increases in grain and meal imports. This result seems entirely plausible, given recent trends in Poland's agricultural trade. According to data of the Food and Agriculture Organization, Poland is currently a net agricultural importer, but net imports have been declining steadily throughout the 1980's. Poland is already a net exporter of food and agricultural products, according to the SITC classification. The controversial aspect of these results, as modelled here, is the implication that Poland's comparative advantage in agriculture lies in pork production and that current policies stressing grain self-sufficiency may not be in Poland's best interest.

Net gain in welfare. Poland realizes a significant net gain in welfare. Producers lose, consumers gain overall, but the largest source of the welfare increase is the decline in government expenditures.

Yugoslavia

Yugoslavia becomes a larger net exporter of all meats. Reform results in production gains of all meats except poultry, ranging from 21-23 percent. Demand is largely unchanged for beef, but rises 10 percent for pork. Demand for poultry declines 9 percent, despite virtually no change in poultry consumer prices. This is the result of the substitution of pork, the consumer price of which declines 21 percent. The result is an exportable surplus of 204,000 tons of poultry.

Substantial increase in net grain imports. Because of productivity gains, production of wheat and corn rises 10 and 6 percent, despite substantial decreases in the producer prices (25 and 31 percent). However, as a result of the decline in consumer prices and the increase in livestock production, demand rises substantially, leading to 1.5 million tons of net grain imports.

Increased imports of oilseeds and meals. Total imports of oilseeds and meals, expressed in soymeal equivalent, rise 16 percent. There is a decline in soybean production, partially offset by an increase in the production of other oilseeds (presumably sunflowerseed). Total demand rises by 4 percent.

Significant decline in net agricultural imports. With reform, Yugoslavia could become nearly self-sufficient in agricultural production, according to the model results. Net imports decline from \$213 million to \$36 million. However, Yugoslavia is also an exporter of fruits, vegetables, wine, and high-valued, processed products. Yugoslav economists expect these exports to increase in the coming decade. The model does not include these products. But, if these products were added in, Yugoslavia could turn out to be a net agricultural exporter following reform.

Net gain in welfare. Yugoslavia's overall welfare gain is in the same range as Poland's following liberalization. However, the sources of that gain are different. Because Yugoslavia's budget subsidies were much lower than Poland's, less of the welfare gain comes from a reduction in government expenditures. Most of Yugoslavia's welfare gain comes from the increase in consumer surplus. Yugoslavia's producers lose more than Poland's.

Evaluation of Results; Directions for Further Research

The model results predict some dramatic changes in the structure of agricultural production and trade in both Poland and Yugoslavia. For example, they suggest that Poland's role as a net agricultural exporter will be entirely driven by the pork sector, that it will remain a net importer of most other products. Yugoslavia, on the other hand, currently a sizable exporter of corn and a very small importer of wheat, is projected to become a large importer of both grains. These are rather strong statements and are heavily dependent on the assumptions used in the model. There are four basic assumptions that could be called into question; these are discussed below.

Productivity Increases

It is obviously far from certain that Yugoslav and Polish farmers will realize the productivity gains assumed in the model. One could object to this analysis on the ground that trade liberalization without simultaneous productivity gains would yield quite different results. In the case of Poland, initial model runs with no assumptions of productivity gains also showed that country becoming a net agricultural exporter. Pork exports were smaller under that scenario, but still significantly larger than at present. The main difference in the results without productivity gains was that they showed Poland more than doubling its grain imports.

Assumptions of productivity gains have more of an effect on the outcome of trade liberalization in Yugoslavia. Initial model results showed that without productivity gains, that country would become a larger net agricultural

importer. Total grain imports would reach 2.6 million tons, and Yugoslavia would become a net importer of all meats.

Calculation of the Price Wedge

For all the commodities, the largest component of the PSE and CSE calculations was the gap between the trade price (or reference price) and the domestic producer or consumer price. As a result, the choice of reference price is crucial. This choice was a particularly thorny problem for the livestock sector. Trade prices for fresh pork, for example, can range between \$1,000 and \$2,000 a ton, depending on the quality. As a result, the PSE calculated for Polish pork can switch from positive to negative with the use of a different reference price. A positive producer price wedge for pork in the case of Poland, instead of the negative one used here, would clearly alter the model results.

To test the model's sensitivity to the choice of reference price, the author calculated a new price wedge for Polish pork using a reference price close to \$1,000/ton and ran the model again using the resulting positive price wedge. Under the same assumptions of productivity increases, the results still showed an increase in pork exports. However, net exports came to 183,000 tons instead of 913,000. The outcome for net beef trade is also very sensitive to changes in the price wedge. With a higher reference price for beef, the results show Poland becoming an exporter of beef instead of an importer.

The Exchange Rate

One could well question the use of the official exchange rate for the PSE and CSE calculations, especially in the case of Poland. It is well-known that before the 1990 reform program, the black market exchange rate in Poland was five times (or more) the official rate, a clear indication that the zloty was grossly overvalued. The black market rate cannot be assumed to be the "real rate" because it results from an artificially constrained supply. This is an important caveat in that what are generally positive PSE's in this work could become negative with the use of a realistic exchange rate. This was not considered such a serious problem for Yugoslavia.

In the case of Poland, an attempt was made to test the sensitivity of the results to the exchange rate. The model was rerun after recalculating the PSE's and CSE's using a doubled exchange rate. As might be expected, the new PSE's showed producers to be heavily taxed, and consumer subsidies became very large indeed. It turned out that, while the new exchange rate altered the magnitude of the net trade changes, the directions of change were largely the same as in the first run. The model results, based on these exchange rate-adjusted price wedges and without productivity gains, show pork exports of about 1 million tons, beef imports of about 300,000 tons, and, once again, grain imports doubling.

The Use of Annual Averages in Periods of Rapid Inflation

Both Yugoslavia and Poland experienced hyperinflation in 1989, and Yugoslavia had been experiencing accelerating inflation since the early 1980's. In 1986 Yugoslavia's inflation was 88 percent, while Poland's was 18 percent. The producer and trade prices, as well as the exchange rates used in these calculations, were all annual averages. As a result, PSE and CSE calculations could be sensitive to the exact timing of harvests, imports, and exports.

This was a real problem for Yugoslavia in 1989, when inflation came close to 2,000 percent. On more than one occasion, grain traders would sign a contract for a certain volume of corn imports because the trade price at that moment was lower than the domestic. However, by the time the corn arrived, the dinar had been devalued to the point where the imported corn was more expensive than the domestic. No attempt was made in this report to address this question. Since inflation was much lower in both countries in 1986, the assumption was that timing was not such a serious problem in that year.

On a final note, because of the relatively large share of agriculture in the GDP of Poland and Yugoslavia, it is likely that there would be a significant income effect from the production gains realized following reform. In a general equilibrium model, the change in income would feed back into the demand equations, possibly counteracting the negative effect of the rise in consumer prices. A recent study by Wainio, Sullivan, and Krisoff endogenizes the income variable in SWOPSIM for the developing economies.⁹ Future work will experiment with that approach in the case of Poland and Yugoslavia.

Conclusions

The model results are sufficiently sensitive to changes in the underlying assumptions that the reader should be skeptical of the absolute magnitude of the changes listed in tables 6 and 7. Nevertheless, the directions of change indicated by the model results have more credibility. It seems clear from this analysis that, assuming it sticks to its present path toward a market economy, Poland has strong potential to become a significant exporter of livestock products (mainly pork) once the short-term disruptions in the economy are worked out. At the same time, it could become a somewhat larger importer of grains and oilseed products.

Yugoslavia's potential to become a net agricultural exporter is not so clear from the results. According to the model results, Yugoslavia will remain a net importer, and if the projected productivity gains do not materialize, Yugoslavia could become a larger net importer than it is now. Yugoslav economists expect that Yugoslavia will become a net exporter. However, they agree with the model results in that they believe Yugoslavia should not be exporting grain. Rather, it should be using its corn to produce higher valued goods for export, such as meat products. Yugoslavia's best export prospects lie in products which were not included in the model: fruits, vegetables, wine, and organically grown produce.

Appendix: Measurement of Support to Agricultural Producers

The monetary effect of the procurement and border intervention policies were measured together through the calculation of the gap between domestic producer prices and the border price. This method was based on the assumption that with a free market and open borders producer prices and border prices would differ only by the costs of transferring the goods from the farm to the wholesaler (transport, storage, and normal markups paid to middlemen). Any difference beyond those costs can be attributed to government intervention.

The value of other subsidies, principally input subsidies, was calculated from budget data published by the government statistical offices. This procedure is rife with problems in that budgetary data were rarely complete, in most cases were reported only on an aggregate level, and were not broken out by commodity. Therefore, a large number of assumptions had to be made in estimating these subsidies. Investment subsidies, while sizable in some cases, were not estimated at all, due to a lack of data.

Price Gap Calculations

Both the Yugoslav and Polish yearbooks provide data on the average procurement prices paid by socialized organizations and the free-market prices. Average producer prices were calculated as a weighted average of the state and free-market prices. For this purpose, all output procured by state agencies was valued at the average state procurement price, while all unprocured production was valued at the free-market price (where available). The assumption behind this procedure was that the free-market price was the opportunity cost of onfarm consumption.

For the most part, the border price, also referred to as the reference price, was the implicit price calculated from value and volume trade data reported by the Food and Agriculture Organization of the United Nations, converted to the local currency according to the official exchange rate. In cases where a country reported both imports and exports of a given commodity, the import price was used if the country was a net importer, and vice versa. In cases where the country was only a very small trader of a commodity, the trade price of a neighboring country was used. For example, the Hungarian border price was used for Polish poultry.

The effects of procurement policies and border intervention components of the PSE's were measured by calculating the gap between the trade price and the free-market price and multiplying that by total volume of production. This value could be either positive (subsidy) or negative (tax). It happens that, for both Yugoslavia and Poland, these values were almost entirely positive.

Use of Budgetary Data on Input Subsidies

The Polish yearbook provided total expenditures from the budget for agricultural subsidies for fertilizer, plant protection agents (PPA's), seed, fuel, and feed. The first four were assumed to apply to crops and were allocated according to area planted. The method of allocation was admittedly crude; it would have been better to allocate subsidies for fertilizers and PPA's according to application rates and seed subsidies according to seeding rates. To date, though, the necessary data are not available. Feed subsidies were attributed to livestock production and were allocated among beef, pork,

and poultry (lamb and mutton production is largely unsubsidized), according to value of production.

The Yugoslavs do not publish such budget data. The only source of input data available to date is figures on fertilizer subsidies supplied by the Agricultural Counsellor in Belgrade. These are reported as a percentage of the price in effect at a given date, usually December of the previous year. This information was used to calculate the subsidies paid per ton of nutrient weight (separately for nitrogen, phosphorous, and potassium), which were then multiplied by total fertilizer consumption. This total was allocated among crops according to area planted. This whole procedure was carried out separately for private and socialized production, since fertilizer application rates are vastly different between the two sectors. Similar data on other subsidies were more elusive in that many of them are paid by the republic governments and vary widely from one republic to another.

Measurement of Consumer Food Subsidies

In all cases, the CSE's represent the gap between domestic and trade prices. The trade prices used were the same as those used in calculating the PSE's. However, before the consumer prices could be compared with the trade prices, the consumer prices had to be adjusted to represent the price of the respective good at the same stage of the production process as the trade price. The price charged at the retail level includes a marketing margin to cover processing, transport, and other marketing costs. It was thus necessary to estimate this margin and subtract it from the retail price in order to calculate the consumer price gap.

In the case of Poland, budget subsidy data were used to estimate the consumer price minus the marketing margin. The Polish yearbook reports aggregate subsidies paid for grain products, meat, dairy products, sugar, fish, and edible oils. Per unit subsidies, calculated on the basis of these numbers, were subtracted from the state producer price to estimate the consumer price. This price was applied to all procured production. The difference between total consumption and the volume of procurement was valued at the free-market price, if available; otherwise at the state procurement price. A weighted average of these prices was computed and that average consumer price was compared with the trade price.

Yugoslavia publishes extensive retail price data, but only limited data on wholesale prices. It does not publish budget subsidy data. Where both retail and wholesale prices were published, there was generally about a 12-percent difference between the two. Wholesale prices were thus estimated by subtracting a 12-percent margin from the retail price. For the meats, an additional margin of 10-12 percent was subtracted from the wholesale price to account for marketing costs.¹⁰ For wheat, the wholesale price for flour (given in the Yugoslav statistics) was converted to wheat equivalent by dividing by a factor of 0.73. Average consumer prices were then calculated as for Poland and compared with the border prices.

¹⁰Based on information provided to the author by Dusan Radmanovic of the Institute for Agricultural Economics in Belgrade, Yugoslavia.

n.a. = Not available.

Entries in parentheses indicate negative numbers.

Appendix table 5--Domestic price definitions: Poland

Commodity	Agent	Definition
Beef	Producer	Annual average state procurement price, calculated from data in Polish statistical yearbook. This price, reported in zloty per ton liveweight, was converted to carcass weight by dividing the liveweight price by the ratio of carcass weight production (not including fat and offals) to liveweight production.
	Consumer	Estimated wholesale price calculated by subtracting budgetary subsidies paid to processors from the average producer prices.
Pork	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Polish statistical yearbook. Converted to carcass equivalent in same way as for beef.
	Consumer	Annual weighted average of free-market price and the estimated state wholesale price estimated by subtracting budgetary subsidies paid to processors from the average producer prices.
Poultry meat	Producer	Annual average state procurement price, calculated from data in Polish statistical yearbook. Converted to carcass equivalent in the same way as for beef.
	Consumer	Annual weighted average of state wholesale price, estimated by subtracting budgetary subsidies paid to processors from the average producer prices, and state producer price, interpreted here as the opportunity cost of onfarm consumption.
Eggs	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Polish statistical yearbook. Price was reported in zloty per egg; this was converted to zloty per ton by dividing by 18,188.
	Consumer	Annual weighted average of free-market price and the estimated state wholesale price estimated by discounting the officially reported state retail price by a margin of 25 percent.
Milk	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Polish statistical yearbook.

Continued--

Appendix table 5--Domestic price definitions: Poland--Continued

Commodity	Agent	Definition
Milk	Consumer	Annual weighted average of free-market price and the estimated state wholesale price estimated by subtracting budgetary subsidies paid to processors from the average producer prices.
Wheat	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Polish statistical yearbook.
	Consumer	Annual weighted average of free-market price and the estimated state wholesale price estimated by subtracting budgetary subsidies paid to processors from the average producer prices.
Corn	Producer	Annual average state procurement price, calculated from data in Polish statistical yearbook.
Barley	Producer	Annual weighted average of average state procurement price and free-market price, calculated from data in Polish statistical yearbook.
	Consumer	Annual average wholesale price paid by Polish livestock producers for feed barley, as reported in the FAO/ECE <u>Price Review</u> .
Rye	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Polish statistical yearbook.
Rapeseed	Producer	Annual average state procurement price, calculated from data in Polish statistical yearbook.
Vegetable oil	Consumer	Annual average state wholesale price, estimated by discounting state retail price by a margin of 25 percent.
Sugar	Producer	Annual average state procurement price for sugarbeets, converted to raw sugar equivalent.
	Consumer	Annual average state wholesale, estimated by subtracting budgetary subsidies paid to processors from the average producer prices.

Appendix table 6--Domestic price definitions: Yugoslavia

Commodity	Agent	Definition
Beef	Producer	Annual average state procurement price, calculated from data in Yugoslav statistical yearbook.
	Consumer	Annual average state retail price discounted by a margin of 25 percent.
Pork	Producer	Annual average state procurement price, calculated from data in Yugoslav statistical yearbook.
	Consumer	Annual average state retail price discounted by a margin of 25 percent.
Poultry meat	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Yugoslav statistical yearbook.
Eggs	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Yugoslav statistical yearbook.
	Consumer	Annual average free-market price of eggs, calculated from data in Yugoslav statistical yearbook.
Milk	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Yugoslav statistical yearbook.
	Consumer	Annual weighted average of free-market price and state wholesale price, estimated by discounting the state retail price by a margin of 25 percent.
Wheat	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Yugoslav statistical yearbook.
	Consumer	Annual weighted average of free-market flour price and state wholesale flour price, estimated by discounting the state retail price by a margin of 25 percent. Both prices were converted to wheat equivalent.

Continued--

Appendix table 6--Domestic price definitions: Yugoslavia--Continued

Commodity	Agent	Definition
Corn	Producer	Annual weighted average of state procurement price and free-market price, calculated from data in Yugoslav statistical yearbook.
	Consumer	Annual weighted average of the free-market price of corn flour, converted to corn equivalent, and the average wholesale price paid by Yugoslav livestock producers for feed corn.
Barley	Producer	Annual weighted average of state procurement price paid for feed barley, the state procurement price paid for brewing barley, and the free-market price, calculated from data in Yugoslav statistical yearbook.
	Consumer	Annual average wholesale price paid by Yugoslav livestock producers for feed barley.
3 6 Soybeans	Producer	Annual average state procurement price, calculated from data in Yugoslav statistical yearbook.
Sunflowerseed	Producer	Annual average state procurement price, calculated from data in Yugoslav statistical yearbook.
Vegetable oil	Consumer	Annual average wholesale price, given in Yugoslav statistical yearbook.
Sugar	Producer	Annual average state procurement price for sugarbeets, converted to raw sugar equivalent.
	Consumer	Annual average wholesale price, given in Yugoslav statistical yearbook.

Appendix table 7--Reference price definitions: Poland

Commodity	Definition
Beef	Annual weighted average of the beef export price calculated from FAO data and the export price of live cattle, converted to carcass weight equivalent.
Pork	Average annual import price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Poultry meat	Average annual Hungarian export price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Eggs	Average annual Hungarian import price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Milk	Average annual Hungarian export price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Wheat	Average annual import price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Corn	Average annual import price, calculated from FAO trade data.
Barley	Average annual import price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Rye	Average annual import price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Rapeseed	Average annual export price, calculated from FAO trade data, converted to zloty using the official exchange rate.
Vegetable oil	Annual weighted average of import prices of soybean and sunflowerseed oil, calculated from FAO trade data.
Sugar	Average annual export price, calculated from FAO trade data, converted to zloty using the official exchange rate.

Appendix table 8--Reference price definitions: Yugoslavia

Commodity	Definition
Beef	Annual weighted average of the export price for fresh beef and live cattle, converted to carcass weight equivalent. The beef price was calculated from FAO trade data. The export price of live cattle was derived by dividing the value of cattle exports reported by FAO by the carcass weight volume given in Yugoslav statistical yearbook.
Pork	Average annual price of Polish pork imports, calculated from FAO trade data, converted to dinars at the official exchange rate.
Poultry meat	Average annual export price, calculated from FAO trade data.
Eggs	Average annual export price, calculated from FAO trade data.
Milk	Average annual export price, calculated from FAO trade data.
Wheat	Average annual import price, calculated from FAO trade data.
Corn	Average annual export price, calculated from FAO trade data.
Barley	Average annual import price, calculated from FAO trade data, converted to dinars using the official exchange rate.
Soybeans	Average annual import price, calculated from FAO trade data.
Sunflowerseed	Average annual import price, calculated from FAO trade data.
Vegetable oil	Annual weighted average of import prices of soybean and sunflowerseed oil, calculated from FAO trade data.
Sugar	Average annual import price, raw equivalent, calculated from FAO trade data.

Reports you can use . . . from ERS

U.S. Agricultural Trade Update

gives you up-to-the-minute information.

Each month the *U.S. Agricultural Trade Update* brings you ERS' most up-to-the-minute data on the farm trade sector. This useful 6-page update brings you the most current figures, *delivered by first-class mail to ensure timely delivery.*

The *U.S. Agricultural Trade Update* covers the monthly farm trade balance, U.S. farm imports and exports by quantity and value, and leading exports and exporters.

A 1-year subscription to the *U.S. Agricultural Trade Update* costs just \$15. Or save by ordering a 2-year subscription (that's 24 issues) for \$29, or a 3-year subscription for \$42.

Situation and Outlook Agricultural Trade Reports

give you the facts . . . and the forecasts!

These reports provide both current intelligence and historical data on international food and agricultural developments. They also forecast how changes in conditions and policies around the world will affect both U.S. and international agriculture.

Outlook for U.S. Agricultural Exports offers the latest value and volume of U.S. farm exports, by commodity and region, as well as the agricultural trade balance, import commodities, and export outlook. ***World Agriculture*** offers production and use data and analyses by commodity and country, along with a review of recent economic conditions and changes in food and trade policies. ***World Agriculture Regional*** reports summarize the year's developments affecting U.S. agriculture and trade in five key regions, and look to the future with articles on market trends, trade, and policy (regional reports include USSR, China, Western Europe, Pacific Rim, and Developing Economies).

The cost is just \$12 for a 1-year subscription per title. Or save by ordering a 2-year subscription for \$23, or a 3-year subscription for \$33.

Call toll free, 1-800-999-6799

in the U.S. and Canada; other areas, please call 301-725-7937.
Or write, ERS-NASS, P.O. Box 1608, Rockville, MD 20849-1608

Get these timely reports from USDA's Economic Research Service

These periodicals bring you the latest information on food, the farm, and rural America to help you keep your expertise up-to-date. Order these periodicals today to get the latest facts, figures, trends, and issues from ERS.

Agricultural Outlook. Presents USDA's farm income and food price forecasts. Emphasizes the short-term outlook, but also presents long-term analyses of issues ranging from international trade to U.S. land use and availability. 11 issues annually. 1 year, \$26; 2 years, \$51; 3 years, \$75.

Farmline. Concise, fact-filled articles focus on economic conditions facing farmers, how the agricultural environment is changing, and the causes and consequences of those changes for farm and rural people. 11 issues annually. 1 year, \$12; 2 years, \$23; 3 years, \$33.

National Food Review. Offers the latest developments in food prices, product safety, nutrition programs, consumption patterns, and marketing. 4 issues annually. 1 year, \$11; 2 years, \$21; 3 years, \$30.

Economic Indicators of the Farm Sector. Updates economic trends in U.S. agriculture. Each issue explores a different aspect of income and expenses: national and State financial summaries, production and efficiency statistics, and costs of production for major field crops and for livestock and dairy. 5 issues annually. 1 year, \$14; 2 years, \$27; 3 years, \$39.

Rural Development Perspectives. Crisp, nontechnical articles on the results of new rural research and what those results mean. 3 issues annually. 1 year, \$9; 2 years, \$17; 3 years, \$24.

The Journal of Agricultural Economics Research. Technical research in agricultural economics, including econometric models and statistics focusing on methods employed and results of USDA economic research. 4 issues annually. 1 year, \$8; 2 years, \$15; 3 years, \$21.

Foreign Agricultural Trade of the United States. Updates the quantity and value of U.S. farm exports and imports, plus price trends. 8 issues annually. 1 year, \$25; 2 years, \$49; 3 years, \$72.

Situation and Outlook Reports. These reports provide timely analyses and forecasts of all major agricultural commodities and related topics such as finance, farm inputs, land values, and world and regional developments. Each *Situation and Outlook* title costs 1 year, \$12; 2 years, \$23; 3 years, \$33. Titles include:

<i>Agricultural Exports</i>	<i>Cotton and Wool</i>	<i>Oil Crops</i>	<i>Vegetables and Specialties</i>
<i>Agricultural Income and Finance</i>	<i>Dairy</i>	<i>Rice</i>	<i>Wheat</i>
<i>Agricultural Resources</i>	<i>Feed</i>	<i>Sugar and Sweeteners</i>	<i>World Agriculture</i>
<i>Aquaculture</i>	<i>Fruit and Tree Nuts</i>	<i>Tobacco</i>	<i>Agriculture and Trade reports</i>

Also available: *Livestock and Poultry*: 1 year, \$17; 2 years, \$33; 3 years, \$48.

Livestock & Poultry Update (monthly): 1 year, \$15; 2 years, \$29; 3 years, \$42.

U.S. Agricultural Trade Update (monthly): 1 year, \$15; 2 years, \$29; 3 years, \$42.

Add 25 percent for shipments to foreign addresses (includes Canada).
