Dairy Imports in Sub-Saharan Africa and the Welfare Implications of Import Policies

Shahla Shapouri
Stacey Rosen

Abstract
Concern over nutritional deterioration and growing food import dependency has increased during the last decade in Sub-Saharan Africa. Between 1961 and 1988, Sub-Saharan Africa's dairy imports increased nearly sixfold, growing at an annual rate of 6.5 percent. This trend is a cause for concern as high import growth is financially difficult to sustain. This paper evaluates factors affecting dairy imports in 19 countries. The results indicate that government policies encouraged import growth in most of the countries included in the study. The welfare effects of import policies, such as direct import or consumer price subsidies, exchange rate overvaluations, and distribution of food aid imports, are reviewed in addition to the policies of exporting countries. The study covered the period 1961 to 1988, with a particular focus on 1977-88, years for which food aid data were available.

Dairy Imports in Sub-Saharan Africa and the Welfare Implications of Import Policies

Shahla Shapouri
Stacey Rosen

Introduction

Concern over nutritional deterioration and growing food import dependency has increased in Sub-Saharan Africa during the last decade. Most food-related studies of the region have focused on the availability of grains because of their importance in the diet and the availability of data. Far less attention has been paid to the livestock and dairy sectors. Population growth, rising incomes, urbanization, and government policies promoting dietary improvements have changed consumption patterns in these countries. With slow domestic production growth, import dependency for commodities such as dairy products has increased significantly. Between 1961 and 1988, Sub-Saharan Africa's dairy imports increased nearly sixfold, growing at an annual rate of 6.5 percent. This trend is a cause for concern as high import growth is financially difficult to sustain.

This paper evaluates factors affecting dairy imports in 39 Sub-Saharan countries, by region, including West Africa (Benin, Burkina Faso, Cameroon, Cape Verde, Chad, Cote d'Ivoire, Gabon, Gambia, Ghana, Guinea, Guinea-Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone, and Togo), East Africa (Burundi, Ethiopia, Kenya, Rwanda, Somalia, Sudan, Tanzania, Uganda, and Zaire), and Southern Africa (Angola, Botswana, Comoros, Congo, Lesotho, Madagascar, Malawi, Mauritius, Mozambique, Zambia, and Zimbabwe).

Factors examined to determine the impact of policies on import growth include income, population, production, and domestic policies. The results indicate that government policies encouraged import growth in most of the countries included in the study. The welfare effects of import policies, such as direct import or consumer price subsidies, exchange rate overvaluations, and distribution of food aid imports, are reviewed in addition to the policies of exporting countries. The study covered the period 1961 to 1988, with a particular focus on 1977-88, years for which food aid data were available.

Overview of International Dairy Market

Total world cow milk production neared 470 million metric tons in the late 1980s. The recent annual production growth of about 1-1.5 percent was less than the historical 2-percent annual growth during the 1970s and the mid-1980s. Europe, the Soviet Union,

and North America (the United States and Canada) account for about 80 percent of world production (1). 1/

Most dairy products are highly processed and are traded largely among higher income countries. An exception is nonfat dry milk which is imported by lower income countries. Only about 5 percent of the world's milk production is traded. Storable products, mainly cheese, nonfat dry milk, butter, and protein components such as casein, dominate dairy trade (fig. 1).

Government policies play a significant role in international dairy trade. The major industrialized dairy producers, except New Zealand and Australia, operate dairy programs that provide relatively high levels of assistance to their dairy sectors (1). In order to maintain domestic supply and demand balances, many countries have used the international market as an outlet for surplus dairy production.

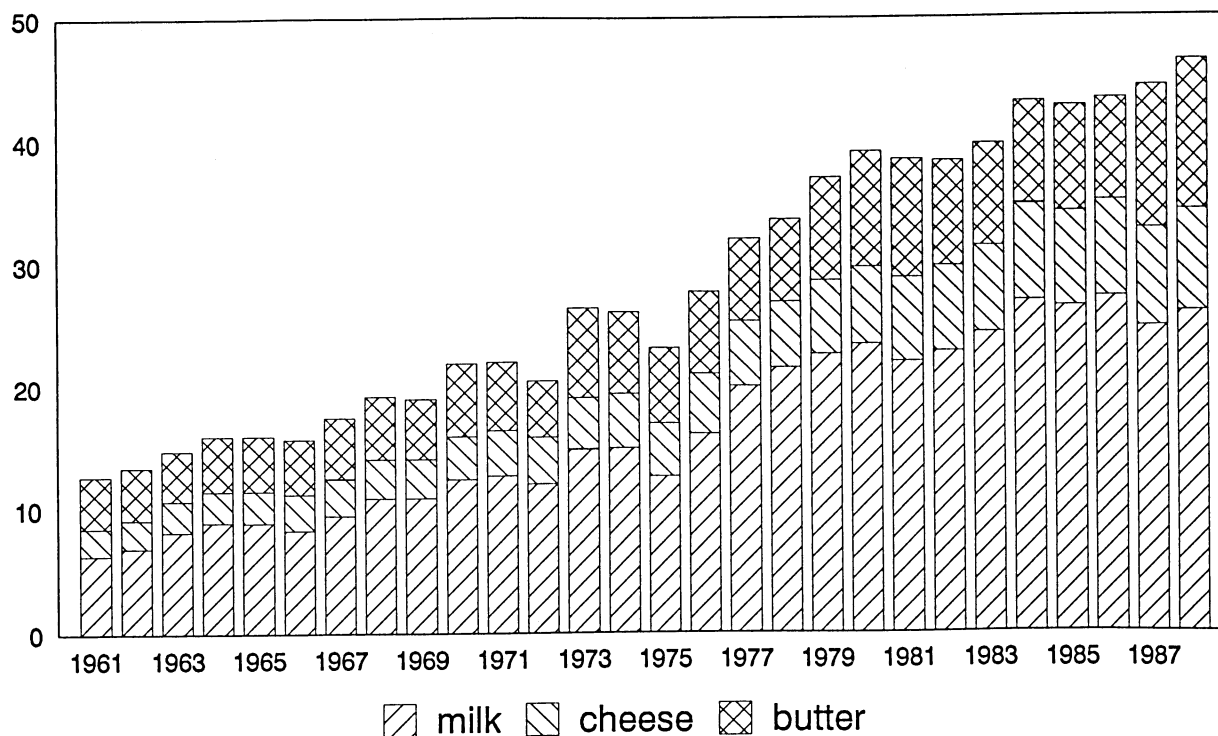

Most milk is consumed where it is produced, either as fluid or manufactured dairy products. The share of traded dairy products has remained stable through time, but the traded quantities have increased with production. Developed countries are large net exporters, while developing countries are large net importers. The EC, New Zealand, and Australia are the most active traders,

1/ Underscored numerals in parentheses indicate items in the Reference section.

Figure 1

World Dairy Exports

million tons

with the EC and New Zealand clearly dominating. Other industrialized countries, such as the United States and Canada, participate in selected product markets. The Soviet Union is the largest importer of dairy products, accounting for half of the world butter trade. The main importers within the developing country group are oil exporters such as Mexico, Venezuela, Algeria, Iran, Saudi Arabia, and Malaysia. These countries have increased their imports since 1989 as prices of dairy products have fallen and oil prices have risen. Imports of most developing countries, however, are constrained by limited foreign exchange availability. This has lowered demand and contributed to the excess supply on the world market, and subsequently depressed prices (6).

Dairy Imports in Sub-Saharan Africa

Dairy product imports by Sub-Saharan countries relative to total world trade are small, but dairy product consumption in some countries depends almost totally on imports. The trend between 1961 and 1987 exhibited an increase of nearly sixfold in Sub-Saharan imports, with an annual growth rate of 6.5 percent (fig. 2). Most of the import growth occurred during 1961-76 (8.4 percent per year) and since then has slowed to less than 1 percent per year. The earlier high rate of import growth most likely stemmed from slow domestic production growth (1.7 percent per year). The latter has not kept pace with the 3-percent population growth for the region (fig. 3).

Figure 2

Sub-Saharan Africa's Dairy Imports

1961=100

Figure 3

Per Capita Milk Production

1966=100

During 1977-88, production performance improved, growing 3.5 percent per year, while import growth slowed to 0.4 percent (based on 39-country statistics). This resulted in little change for both the self-sufficiency ratio (production as a percentage of consumption) and the average per capita consumption levels (fig. 4). The average dairy self-sufficiency ratio, about 95 percent in the early 1960s, fell to 83 percent during 1977-88.

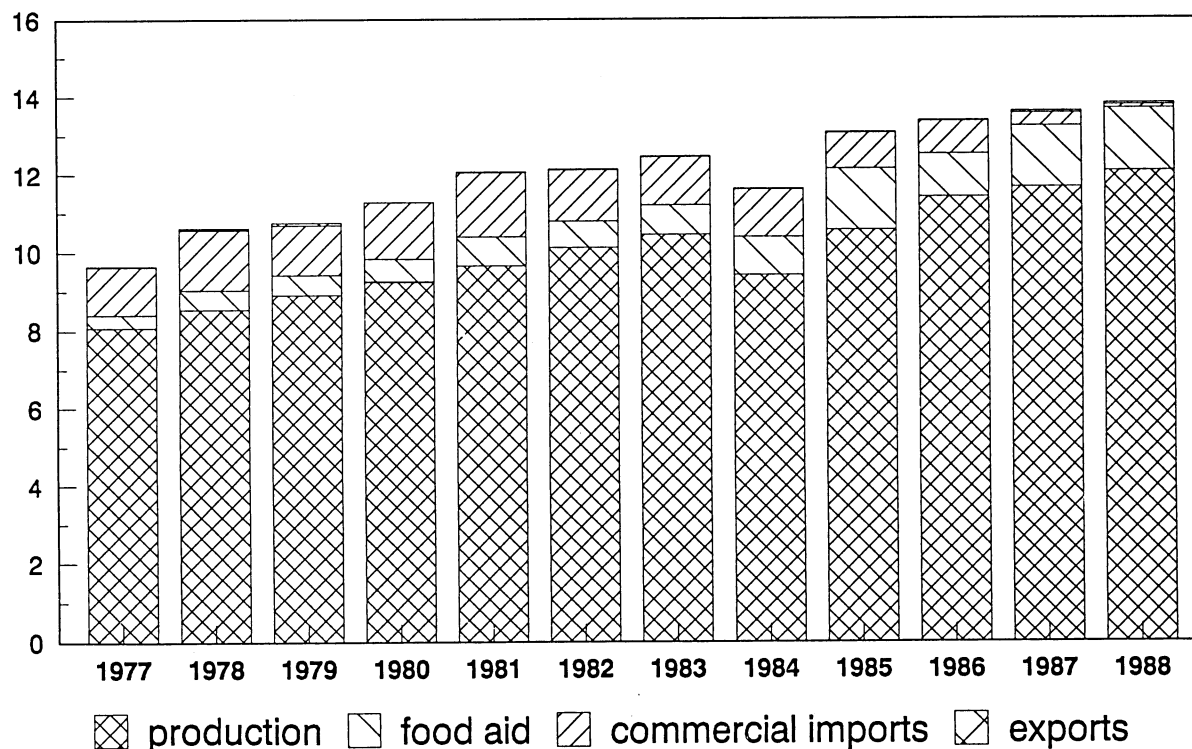

On the sub-regional level, the rate of import growth during 1977-88 was the highest in East Africa (3.7 percent), followed by Southern Africa (1.7 percent) and West Africa (-1.6 percent). The import dependency ratio (imports as a percentage of consumption) showed a contrasting pattern, with East Africa being the lowest import dependent sub-region (6 percent average), followed by Southern Africa (36 percent) and West Africa (42 percent).

Individual country import growth rates varied significantly (table 1). Of the 39 countries studied, Kenya and Zimbabwe were net exporters of dairy products until the early 1980s. The range of annual import growth for the remaining 37 countries was from a decline of 21 percent in Zambia to an increase of 18 percent in Sudan. Three countries registered import growth of more than 15 percent per year (Ethiopia, Rwanda, and Sudan). This high rate of import growth was due to the low level of imports in the base period, so that even with the high import growth, their import

Figure 4

Components of Sub-Saharan Dairy Consumption

million tons

dependencies remained low (less than 13 percent in Ethiopia, 21 percent in Rwanda, and 4 percent in Sudan in 1986-88).

In countries with declining rates of imports, the annual range was from -0.03 to -21 percent. These include Cape Verde, Ghana, Guinea-Bissau, Liberia, Nigeria, Somalia, Tanzania, Madagascar, and Zambia. In all, with the exception of Cape Verde, Ghana, Liberia, and Madagascar, lower imports significantly reduced import dependency.

The highest dairy import dependent countries were Cape Verde, Cote d'Ivoire, Gabon, Zaire, and Congo, with imports contributing more than 85 percent of consumption in 1986-88. The countries with the lowest import dependencies, less than 10 percent, included Chad, Kenya, Somalia, Sudan, Tanzania, Uganda, Zambia, and Zimbabwe (table 2).

Commercial and Food Aid Imports

Since 1977 (the year aid data on dairy products became available), the food aid share of total dairy imports has increased markedly, from 21 percent in 1977 to 83 percent in 1987 (fig. 5). Of the 39 countries studied, Cote d'Ivoire, Gabon, and Nigeria did not receive any dairy aid during the study period. Benin and Liberia were food aid recipients in the earlier years, but were not during 1984-88. The reverse was true in Kenya and

Figure 5

Dairy Imports: Food Aid vs. Commercial

Zimbabwe, where significant levels of dairy aid were received since only the early 1980s.

The growing food aid dependency of these countries is of great concern. From 1977-79 to 1986-88, the aid share of total dairy imports increased in 14 countries. During 1986-88, dairy aid contributed more than 50 percent of total dairy imports in 15 countries and this share exceeded 75 percent in 4 of these countries (table 2). This high rate of aid dependencies for countries with low self-sufficiency ratios, such as Cape Verde and Ghana, means establishing consumer habits that may be difficult to support financially in the long term. The current level of food aid, if not reduced, is not expected to grow much, particularly if the current GATT negotiations lead to a decline in surplus commodities. Consequently, with a growing import dependency in most countries and a history of commitment to consumers, governments may be forced to import commercially, thereby further straining their limited financial resources.

Factors Affecting Imports

The key factors shaping imports are market demand and supply, and policies. Both domestic and international policies are expected to influence import levels.

Demand Pressure

Total consumption of dairy products is derived by adding production to net imports. Changes in stocks are not included because of the lack of data and the short shelf-life of most dairy products. Average annual consumption growth for the region during 1977-88 was 3 percent, the same as population growth.

Income growth did put a major pressure in increasing demand for dairy products in some countries (table 3). From 1977-88, per capita income for the Sub-Saharan region grew only about 1 percent per year, and when Nigeria is excluded, the growth rate decreases to near .05 percent (8). In fact, positive income growth occurred only during the late 1970s, and since then (1980-88) the per capita income trend was -4 percent; without Nigeria, the rate of decline slows to near -3 percent (8).

During 1977-88, per capita income declined in 14 countries and stagnated in 3 (table 3). Few countries performed well. Cameroon, Burundi, and Botswana had the highest annual per capita income growth, ranging from 7 to 9 percent.

In addition to income, changes in commodity prices are key determinants of consumption. However, lack of price data leaves a major gap in demand analysis for dairy products. Given the recent declining trends in international dairy prices, and the consumer oriented policies of these governments, changes in prices are expected to have a limited impact on dairy consumption in these countries. Hence, population growth remains the principal force behind consumption growth. As a result, maintenance of constant per capita consumption levels translates into a 3-percent annual increase in future demand.

Production Performance

According to FAO production estimates, from 1961 to 1977, total milk production in the region grew about 30 percent, an annual growth rate of less than 2 percent. From 1977 to 1988, production expanded 3.5 percent per year. While the region's share of world production is very low, about 1 percent, its population share is about 12 percent.

Sub-regional milk production growth and the share of total Sub-Saharan production have varied considerably. West Africa, with the largest population, had the lowest production growth and held only a 13-percent share in 1988. East Africa had the highest annual growth, at more than 4 percent, and the highest share of total production, 79 percent. Southern Africa, which accounted for 7.5 percent of total production in 1988, achieved annual production growth of about 2.3 percent. In per capita terms, output was highest in East Africa, 49 kilograms (kg), followed by Southern Africa, 13 kg, and West Africa, only 8 kg.

In Sub-Saharan Africa, most dairy output is produced by pastoralists and agropastoralists, with traditional objectives of subsistence and survival over long periods of drought and regeneration (18). Each family requires a basic stock of animals for survival. However, as families expand, this stock is expanded. Consequently, overstocking and overgrazing caused a deterioration of the rangelands. Milk yields of these producers are low. For example, in Ethiopia, a livestock exporting country, cows do not reach maturity for 3 to 4 years, calve every 2 years, and produce only about 250 kg of milk per lactation (24). This is a very low yield, even compared with neighboring

countries. In Egypt, for example, the average estimated milk output per native cow is between 578 to 756 kg per lactation (19).

The commercial dairy sector, which comprises a small share of production, is operated both by the government and the private sector. Large state-run farms use specialized management skills which minimize input supply and transportation problems and have substantial economies of scale. However, in most cases, they are faced with high production costs, and require subsidies in order to operate. The high costs stem from shortages of skilled labor, the use of highly capital-intensive technologies, and reliance on purchased feed rather than pastures.

The smaller commercial units within the private sector are more efficient and could increase their output significantly if sufficient production incentives were in place (24, 25, 26). The limited available information about the performance of small dairy producers in the region provides encouraging signs for production growth. One example of a successful smallholder dairy program is in Kenya (26). The Kenyan dairy development program includes a marketing system based on a cooperative structure, the provision of technical services, a reform in the pricing policy, a national artificial insemination service, a presence of large high grade herds, and a relatively well developed agricultural infrastructure. Here, parastatals were more successful, not in their production role, but in their work as a service center providing artificial insemination and female stock for distribution. Increased production has led to increased per capita dairy consumption, which stands at 52 kg compared with 25 kg for the region. About 75 percent of the output is accounted for by smallholder farms.

In most countries, poor animal health, with a large number of losses, remains the major problem for the dairy industry. Up-graded animals are more vulnerable to disease than are local breeds. The shortages of veterinary services and the lack of low cost health treatment remain major obstacles. In some countries, limited resources restrict production growth. In Somalia, for example, where the livestock sector is the major component of GNP, the World Bank estimates that the capacity of the range to sustain additional animals was at or near its limit (25). There are also limits to increasing feed supply on the range. Land degradation, resulting from large human and livestock population growth and increased agricultural activities in the areas with marginally higher rainfall and better soils, means that maintaining current production levels will be difficult.

Domestic Policies

The influence of different domestic policies, although not always quantifiable, are expected to have a significant influence on the growth of dairy imports in the region. Two sets of domestic policies affect commodity imports: (1) general economic and trade policies (indirect effect), and (2) specific commodity policies (direct effect) (20).

The economic policies of Sub-Saharan African countries during the last two decades focused on protecting the industrial sector (3). Import substitution policies were employed to stimulate domestic production based on the objective of satisfying domestic demand and eventually exporting.

Industrialization was thought to be the engine of growth and thereby the key to transforming traditional economies. Agriculture was perceived as playing a secondary role, as provider of raw materials for agri-industry, and as a source of tax revenues to support other development activities. To achieve these goals, regulations to control prices, restrict trade, and allocate foreign exchange were instituted. The low priority given to agriculture encouraged labor and capital to flow into the urban areas. And, in order to satisfy the growing urban demands, government intervention in the food sector grew.

Although the degree of government intervention has varied by commodity and country, producer prices for most basic foodstuffs have been legally controlled (16). In recent years, the trend is toward less intervention. The major criteria used for the determination of producer prices include the following, often conflicting, basic elements: cost of production, fair return to producers, fair price to consumers, import-export parity price, crop profitability, food security, and political acceptability. The relative weights accorded these criteria by the governments vary through time, but a fair price to consumers and political acceptability held great importance in most countries.

Government policies in milk deficit countries were frequently oriented toward maintaining low milk prices for consumers, thereby discouraging domestic production and encouraging reliance on imports (23). In countries where a commercial food sub-sector exists, such as Zimbabwe, farmers who market their commodity commercially are most affected by government-set prices and regulations on production and marketing. This sector is generally more responsive to the price at which the government agrees to purchase all quantities offered for sale. The impact of government policies on traditional farmers (the category most dairy producers fall under) is smaller because they market most of their output through informal channels. Therefore, the effective price at which they sell can vary from the government set price. To improve the productivity of the traditional producers, current research puts more emphasis on nonprice factors such as efficiency of the marketing system, and effectiveness of government-sponsored research and extension and credit.

Because of the generally small and highly variable marketed volumes of milk by traditional producers, dairy imports have become a more reliable source of supply. Import dependent milk processing plants have received government supported price subsidies and investment. Tariffs, although varying by country and commodity, did not reduce imports. Overvaluation of exchange rates in most countries has contributed to the subsidization of imports. Members of the urban population, middle and upper

income, who are primary consumers of imported dairy products, were influential in setting government policies supporting dairy imports.

Domestic policies were not the only reason for the sharp rise in dairy imports. Protection and subsidy policies at the international level also influenced import demand. Extensive domestic producer support programs in countries such as the EC and the United States (producers' subsidy equivalent in the range of 30 to 70 percent of the value of production during 1982-87) led to an increase in surplus milk production. With an excess supply of dairy products, these imports have been relatively cheap.

Contribution of Selected Factors to Import Growth

In an assessment of the forces influencing dairy import growth, an analysis of the impact of factors affecting dairy supply and demand is essential. Among the factors affecting milk supply are input prices, producer prices, prices of competing commodities, choice of technology, and weather. Factors shaping demand include population, income, commodity prices, and prices of substitute products. An analysis of dairy market behavior is not possible with currently available data, and because dairy products are not homogeneous. Another complication is the subsistence nature of the dairy industry in Sub-Saharan Africa. The response of subsistence producers to economic signals is expected to be different from that of commercial producers, but there is little research available to assess this proposition.

To measure the contribution of supply and demand growth, as well as the impact of consumer policies on import growth, we used a commodity balance identity, similar to V.H. von Massow's approach. The only difference is that food aid is added as a separate source of supply. It was assumed that in a given time period, commercial imports are the residual of demand, domestic supply, food aid, and stock changes. This yields the following relationship:

$$M_t = C_t + S_t - Q_t - FA_t - S_{t-1} \quad (1)$$

Where M_t is net commercial imports, Q_t is domestic production, FA_t is food aid, S_{t-1} is beginning stocks, C_t is consumption, and S_t is ending stocks. Changes in stocks are assumed to be small because of the short shelf-life of dairy products. The one period changes in the variables, weighted by total consumption in the base year, are derived as follows:

$$M/C * dM/M = dC/C - Q/C * dQ/Q - FA/C * dFA/FA \quad (2)$$

Equation 2 indicates that the relative change (between two periods) in imports are equal to relative change in total consumption, minus relative change in production and relative change in food aid (for simplicity, subscripts are omitted).

The change in total consumption (C) is specified as a function of population growth (P), per capita income growth (Y), and all other policies affecting consumption (z). Substituting these factors for consumption growth, one can write equation (2) as follows:

$$dM/M = C/M (dP/P + e * dY/Y + z - Q/C * dQ/Q - FA/C * dFA/FA) \quad (3)$$

where e is the income elasticity of demand for dairy products. The population elasticity is assumed to be one. The sign of z could be positive or negative depending on government consumption policies. Reorganizing equation 3 in terms of z and substituting commercial import share (CMS) for M/C yields the following equation:

$$z = (M/C * dM/M) - dP/P - (e * dY/Y) + (Q/C * dQ/Q) + (FA/C * dFA/FA) \quad (4)$$

From equation 4, the residual proportion of import growth that cannot be explained by growth in population, income, production, and food aid can be derived as follows:

$$z^* = C/M * z \quad (5)$$

Table 4 summarizes the residual import growth rates, z^* , and those of other variables for the period 1977-88. All calculations are based on average annual changes between the average of 1977-79 and 1986-88. To measure the impact of income growth on demand, we used an income elasticity of 0.68 (FAO estimate of income elasticity for dairy products for the region in the mid-1970s) for all countries. The actual income elasticity for individual countries is expected to vary from this average, but the range is probably small because of the narrow range of per capita income levels. The positive sign of z^* indicates that other factors including government policies were responsible for encouraging dairy imports.

The results support the proposition that policies stimulate commercial imports in the region. The residual z^* was positive in 27 of the 39 countries, indicating that in addition to population, income, production, and food aid growth, other factors including government policies influenced the growth in commercial dairy imports. Kenya and Zimbabwe were excluded as they became importers of dairy products after 1980 and most of their imports were supplied through aid.

In 10 countries, the impacts of other factors including policies were negative. One explanation for this import pattern is limited foreign exchange availability. Most of these countries have been faced with severe financial difficulties since the early 1980s and the impacts of financial constraints are expected to be greater on countries with high import dependency. Countries with negative residuals of import growth and high import dependencies were Cape Verde, Ghana, Zaire, and Mauritius (the range in import dependencies was from 75 to 90 percent). In the less import dependent countries of Nigeria, Sierra Leone,

Burundi, Madagascar, Malawi, and Zambia, policy adjustments, in particular exchange rate adjustments, aimed at curbing consumption due to severe financial pressures were the likely reasons for restrictive import policies.

A test of the significance of the impacts of international prices and exchange rate policies on growth in the volume of commercial dairy imports was performed. A simple model was constructed, regressing growth in imports against real world prices for dairy products and a variable called distortion in exchange rates (DEXR). DEXR is the ratio of an adjusted exchange rate to an official exchange rate. The official exchange rate is the number of units of domestic currency per U.S. dollar. The adjusted exchange rate is calculated by adjusting the official exchange rate in the base period (1978) by the index of a real effective exchange rate (the nominal exchange rate adjusted by the ratio of the domestic price level to the average price level of the trading partners). This adjusted rate represents the real exchange rate if the base period exchange rate is in equilibrium. However, distortions in exchange rates did exist in the base period, with varying degrees depending upon the country. Regardless of the degrees of distortions in the base period, however, the ratio of adjusted exchange rate and official rate (DEXR) shows the direction of overvaluation of the official rate. A DEXR of more than one indicates that exchange rate overvaluation has increased, while a DEXR of less than one indicates a correction in overvaluation.

The expected dairy import relationship with DEXR is positive, meaning that an increase in overvaluation leads to an increase in imports. The expected relationship between commercial dairy imports and real dairy import prices (Netherlands dried skim milk divided by the U.S. CPI) is negative. The regression estimation method is OLS and the period of coverage is from 1978 to 1988. The short study period is due to insufficient data both for commercial imports and the index of real effective exchange rates.

The estimated results are shown in table 5. The explanatory power of the exchange rate distortions and real world prices ranged from 7 percent in Togo to 56 percent in Benin. This means in addition to distortions in exchange rate policies, and changes in the world market prices, other factors were responsible for changes in commercial imports. In all countries, DEXR and commercial dairy imports had the expected positive relationship. The coefficient of DEXR, however, was statistically significant in 15 countries (significant at 1- to 10-percent levels). These results indicate that further exchange rate adjustments in the region will lead to a decline in commercial dairy imports.

The policy of exchange rate adjustment which has been adopted by most countries since the early 1980s is expected to continue although details of devaluation vary considerably. According to available reports, this policy has revitalized exports and improved production of import substitute commodities, including food, in many countries (8, 27).

* denotes significance at 10-percent level.

The relationship between dairy imports and real import prices was negative in all countries except Togo and Lesotho. The coefficients of world prices were statistically significant in 16 countries (at the 1- to 10-percent levels). This means that policy changes in the exporting countries and an increase in world price will lead to a reduction in commercial imports by the region. Among the sub-regions, southern countries were most responsive to both price and distortion in exchange rates (both variables were statistically significant in 6 of the 10 countries).

The short period of the data, however, does not allow for the capture of the long-term relationship between variables which can affect the estimated results. Further research should provide a better understanding of the import response to changes in policies.

Expected Welfare Effects of Dairy Import Policies

In theory, in order to evaluate the domestic welfare effect of import policies, the concept of consumer and producer surplus is used (10). Consumer surplus is based on the assumption that there is a demand for a commodity which responds negatively to a price increase. The notion of producer surplus follows from neoclassical production theory. A firm's shortrun supply function is its marginal cost curve, above the minimum average variable cost. Assuming no input price effects, the horizontal sum of individual firms is the market supply function. The area under the industry's marginal cost, or supply, is the total variable cost. The area above the supply function and below the price is producer surplus or rent (producers will receive the same price for all previous units). With a positive supply function, increases in prices lead to increases in producer surplus and vice versa. The producer surplus takes into account the extra costs to the producers associated with responding to higher prices.

The consumer and producer welfare effects of dairy imports depend on the magnitude of price changes, price elasticities of demand and supply, and government policies. The decision on policies are in general made at the national level, but nations are connected internationally by trade which both constrains and expands the scope of national action. Therefore, to measure the impact of imports on the domestic economy, an analysis of policies of both importing and exporting countries is essential. The evaluation of overall food policies in most African countries indicates that policies were aimed at protecting consumers (23). The import policies aimed at keeping consumer prices at low levels fall into the following categories: (1) direct dairy import or consumer price subsidy, (2) exchange rate overvaluation, and (3) food aid imports. In the international market, the export policies of exporting countries have a direct impact on world prices, and hence on the import levels of importing countries.

Import and Consumer Price Subsidy

The single commodity impact of a direct import subsidy policy is shown in figure 6. Import subsidies cause domestic consumer and producer prices to be lower than world prices. As a result, the domestic output of dairy products declines (from Q_a to Q_c), the amount consumed rises (from Q_b to Q_d), and imports are larger than they would be if the subsidies had not existed (from Q_aQ_b to Q_cQ_d). The government uses budget resources to reduce the price of dairy imports which thereby increases the consumers surplus. In the short term, assuming all other factors remain constant, when consumers gain, producers lose because production, sales, and profits are lower than without intervention. In effect, producers are forced to transfer income to consumers.

In Sub-Saharan Africa, urban consumers are the primary beneficiaries of the subsidy policies (23). With a substantial portion of dairy products directed to the urban areas, a new pattern of dairy consumption, especially among the middle and higher income groups, was promoted. It has been argued that the consumer subsidy policies were the impetus behind the increasing rate of migration to the urban areas (3). In Sub-Saharan Africa, the proportion of urban population nearly doubled during the last 20 years from 14 percent in 1967 to 27 percent in 1987. The annual rural migration rate is about 7 percent. This means that a subsidy policy aimed at satisfying the growing urban population

Figure 6

Impact of Import and Consumer Price Subsidy

will result in soaring budget costs in the future. In the case of African dairy policies, consumer subsidy policies have often led to subsidization of the dairy processing industry. The processing industry relies heavily on imported milk because of the high variability in domestically marketed quantities, a result of frequent drought and/or poor marketing infrastructure.

On the producer side, the long-term consumer subsidy policy and low producer prices have reduced the pace of commercialization of the dairy sector. Commercialization of the subsistence agricultural sector is the cornerstone of development. Commercialization is expected to improve the distribution of incentives and benefits by providing growth linkages with other sectors of the economy. In Africa, since most dairy producers are small farmers, the economic gains from commercialization are expected to improve the welfare of a large portion of the rural population.

Exchange Rate Policy

The impact of exchange rate overvaluation is similar to that of the import subsidy. An overvalued exchange rate means a reduction in the domestic price of imported commodities. The low imported price reduces the domestic price level, from P (world price) to P^1 , as shown in figure 7. Overvaluation does not have a direct impact on budget expenditures for the government but the

Figure 7

Impact of Overvalued Exchange Rate

rest of the economy is forced to pay the costs. Overvaluation of the exchange rate is the primary cause of the trade imbalance and the poor agricultural performance of the region. With the exception of CFA (franc zone) countries, official exchange rates were fixed at the nominal level until the early 1980s. Governments relied on import restrictions rather than devaluation to conserve foreign exchange. Import priority was given to essential commodities such as food, raw materials, and capital goods. The overvaluation, when combined with direct consumer subsidy policies, has had a strong depressing impact on producers' incentives and welfare.

Food Aid

The impact of food aid varies depending on government policies. If food aid is sold at less than the import price, the effect on consumer and producer welfare is similar to that of an import subsidy policy. It leads to consumer gains and producer losses, with no change in the government budget. The extent to which food aid supplements commercial imports is not clear and varies depending upon the policies of the recipients. Most studies of individual countries found that nonemergency food aid displaces commercial imports at rates ranging from 30 to 90 percent (12).

If food aid is used to displace commercial imports and is sold at the world price, there is no change in consumer or producer

Figure 8

Food Aid Displacing Commercial Imports

welfare (fig. 8). The country's financial gain, area YZQ_aQ_b , is equal to the value of food aid at the international market price. The local currencies generated through the commercial sale of food aid, similar to any financial aid, can be invested to improve the performance of the local dairy industry. In 1989, under the U.S. food aid program Titles I and III, 25 agreements were reached with developing countries that mandated the use of local currencies generated from sales of food aid for improving production and marketing of food products (7).

The impact of targeted food aid, where it is distributed in the country in a way that creates new demand rather than substituting for or competing with the existing demand, is a gain to consumers, but with almost no change in producer welfare. In this case, in addition to supply shift from S to S' , income generated food aid shifts the demand curve from D to D' (fig. 9). The consumer welfare gain is the area between the two demand curves which is above the price P . The benefit of targeting food aid is the reduction of food insecurity without removing producers' incentives, at least in the short term (14). An example of targeted food aid is the "food for work" scheme. A discussion of the limitations of this type of program is beyond the scope of this study, but one point which can be made is that providing subsidized dairy products to lower income groups encourages consumption patterns that entail a long-term import

Figure 9

Impact of Targeted Food Aid

dependency. One option for using both food aid and encouraging local employment is "cash for work" which is financed by sales of food aid. This type of program can be used to support public projects, especially in the areas of road and other infrastructure construction. Markets for livestock and dairy products are generally constrained by the lack of infrastructure. Any improvement in market infrastructure has both the potential to improve marketing channels and to promote food security.

International Market

Governments of the dairy exporting countries have extensive programs to support their producers (1). These interventions tend to alter conditions in the world markets as seen by other countries. The world price impact of commodity support policies is shown in figure 10. Without these price supports, the price established in the international market is "P", consumption in country A is OC_a , and production is OQ_a . Country B imports are Q_cQ_d . Suppose country A establishes a price support program at P' , above P. At P' , the export quantity is C_bQ_b . The excess export quantity will reduce the world price to P'' and the unit export subsidy is $P'P''$. The support and export subsidy programs

Figure 10

Export-Import Effects of Export Subsidy Policy

in country A raise the price, reduce consumption, and increase exports. The effects of lower international prices in country B are reduced production, and increased consumption and imports (assuming no market intervention by country B).

The major exporting countries have employed a variety of policies to protect their industries. These policies include direct producer subsidies, direct income payments, border measures to influence exports and imports, and supply management.

Any movement toward liberalization of the dairy market will have significant implications on trade because only 5 percent of total dairy production enters the international market. The countries that will be most affected by dairy trade liberalization are Australia, Canada, the United States, EC, Japan, New Zealand, and non-Western Europe (1). Most of the trade in dairy products is concentrated among the industrialized countries, with developing countries being a major importer of only nonfat dry milk. Estimation of the dairy price impact from trade liberalization varies depending upon the structure of the model and the time frame. The estimated range of price increases is from 30 to 95 percent (1). The increase in world prices is much less than the subsidies paid to the producers of the exporting countries and is expected to reduce surplus milk production in these countries. The implication of trade liberalization on the volume of trade is not clear. While some studies show increases in international traded volume, they fail to address the impact of removing high export subsidies which have shaped historical trade patterns. Removing export subsidies, direct subsidies, and dairy aid, if not replaced by increases in commercial trade at international prices, will lead to a decline in traded volume.

The GATT negotiations are reaching their final stages and the outcome is uncertain. Among various proposals considered, a group of net food importing less developed countries suggested that concessional sales and financial grants could be used to offset the impact of higher world food prices for essential commodities. The proposal by the United States recognizes the need to continue food aid programs to help developing countries and suggests establishing a committee to periodically review the required level of food aid. The proposal also gives an expanded role to multilateral and private voluntary organizations for distribution of food aid.

As for African countries, with their growing import dependencies, higher international dairy prices mean a reduction in the volume of commercial imports and probably higher import costs. The changes in food aid distribution policies, however, could be positive for the region. If the political considerations of food aid distribution policies are replaced by a "needs" criteria, the Sub-Saharan share might increase.

Welfare implications for the consumer are expected to vary by country depending upon the level of price increases, food aid volume, and domestic production performance. In any event, increases in international dairy prices, if transferred to the

domestic market (assuming food aid is used to shift domestic demand), mean a reduction in consumer surplus. On the other hand, if an increase in international prices is passed on to the producers, incentives for production will increase, and for some countries, export earnings will rise.

Conclusions

During the 1980s, providing adequate food supplies became an increasingly severe problem. Sub-Saharan Africa became characterized by declining average per capita food production and high year to year variability. Although food import dependency increased, per capita consumption stagnated or even, in the case of some countries, declined.

Between 1961 and 1988, Sub-Saharan Africa's dairy imports increased nearly sixfold, growing at an annual rate of 6.5 percent. Import growth has slowed since the mid-1970s as production performance improved. Import dependency (imports as a percentage of consumption) averaged 17 percent during 1977-88.

The growth in food imports, including dairy imports, and the subsequent costs, is disturbing for most policymakers in Sub-Saharan countries. The need to conserve foreign exchange is put forward as a main reason for adopting food self-sufficiency policies and curbing imports. Over the years, different policies, such as foreign exchange control, import licensing, and import tariffs, have been adopted in order to reduce imports. The implementation of these policies was not seriously pursued. The contradicting policies such as currency overvaluation and declining import prices reduced the visible costs of imports. This, combined with slow production growth and escalated demand pressures, precluded the governments' enforcement of import restrictions.

With income and population rising, particularly in urban areas, demand for dairy products is expected to grow and dairy will become a more important part of the diet. Using the historical trend in population and projected income growth (per capita income growth in the range of 1 to 2 percent), along with the average income elasticity for dairy products, yields a 4- to 5-percent annual growth in dairy demand until the year 2000.

Delivering this quantity increase will be difficult. Even with a significant increase in public investment, production expansion will be limited in most countries, particularly if they depend on imported feed. The average annual growth in gross investment for the region was -7.3 percent during 1980-88 compared with -2.1 percent for all low-income countries, excluding India and China. Short-term strategies such as increasing the size of herds will not necessarily lead to production improvements because of shortages in feed availability. Long-term production expansion requires increases in investment and improvements in the collection of information on the size and system of dairy operations in these countries. If a country does not have a

comparative advantage in dairy production, it can earn more foreign exchange by diverting resources from dairy production into areas in which it has a comparative advantage. The recent adjustments in the dairy program in the United States are a good example of the long-term policies to promote production and the consequences: budgetary pressures and growing costs, which forced a reduction in subsidies.

Growing demand for dairy products and limited availability of resources mean that achieving self-sufficiency in dairy products in most of the Sub-Saharan countries is almost impossible, certainly in the short term and probably in the long term as well. Recent policy directions, which advocate the curtailment of imports and the conservation of foreign exchange, place considerable pressure to limit commercial imports. Consequently, the dairy self-sufficiency policy will be successful only if countries are willing to accept continued low levels of dairy consumption.

The share of dairy products in the diet is low, on the average less than 5 percent of total per capita calorie intake (table 6). The region's nutritional status, while varying by country, is on average poor; caloric consumption is 15 percent less than the average for low-income developing countries. Because of this, any decline in the availability of essential foods such as dairy products, if not replaced by an equally nutritious food item, can be detrimental.

The study found that the food aid contribution to dairy consumption in Sub-Saharan countries has grown rapidly. The food aid share of total imports increased from 21 percent in 1977 to 83 percent in 1987. Surplus dairy output in the largest exporting countries is expected to continue and to play a role in the food aid picture (figs. 11 and 12). The Sub-Saharan food aid share can grow, from 10 to 30 percent of total dairy aid during 1977-88, if the distribution policies of donors are shifted more toward needy countries. Food aid, if used effectively, can improve nutritional levels, as well as the financial situations of these countries without having a major disincentive on production. Monetization of dairy aid, through sales in the recipient countries, will not interfere with the functioning of local markets. The funds generated from sales could be used to improve market infrastructure and productivity of the dairy sector. It is, therefore, the responsibility of the recipient countries to use food aid effectively as an investment tool and in support of long-term improvements in food security.

Table 6--Per capita consumption growth, role of dairy in diet, and nutritional status in Sub-Saharan Africa

Country	Per capita consumption growth 1977-86	Contribution of dairy in the diet	Calorie intake as percentage of LIC's 1/

Reports you can use . . . from ERS

U.S. Agricultural Trade Update

gives you up-to-the-minute information.

Each month the *U.S. Agricultural Trade Update* brings you ERS' most up-to-the-minute data on the farm trade sector. This useful 6-page update brings you the most current figures, *delivered by first-class mail to ensure timely delivery.*

The *U.S. Agricultural Trade Update* covers the monthly farm trade balance, U.S. farm imports and exports by quantity and value, and leading exports and exporters.

A 1-year subscription to the *U.S. Agricultural Trade Update* costs just \$15. Or save by ordering a 2-year subscription (that's 24 issues) for \$29, or a 3-year subscription for \$42.

Situation and Outlook Agricultural Trade Reports

give you the facts . . . and the forecasts!

These reports provide both current intelligence and historical data on international food and agricultural developments. They also forecast how changes in conditions and policies around the world will affect both U.S. and international agriculture.

Outlook for U.S. Agricultural Exports offers the latest value and volume of U.S. farm exports, by commodity and region, as well as the agricultural trade balance, import commodities, and export outlook. Subscription includes 4 issues. ***Agriculture and Trade*** reports summarize the year's developments affecting U.S. agriculture and trade in five key regions, and look to the future with articles on market trends, trade, and policy (subscription includes 5 regional reports: USSR, China, Western Europe, Pacific Rim, and Developing Economies).

The cost is just \$12 for a 1-year subscription per title. Or save by ordering a 2-year subscription for \$23, or a 3-year subscription for \$33.

World Agriculture

gives you the latest information on world markets.

This periodical gives you timely analysis and forecasts about how the world economy affects agricultural supply and demand. Emphasizes implications for global and U.S. agricultural trade.

The cost is just \$21 for a 1-year subscription. Or save by ordering a 2-year subscription for \$41, or a 3-year subscription for \$60.
