Documentation of the <u>Dynamic World Policy Simulation</u> (DWOPSIM) Model Building Framework. By Vernon Oley Roningen, Agriculture and Trade Analysis Division, Economic Research Service, U.S. Department of Agriculture, Staff Report No. AGES 9226.

Abstract

This report documents the dynamic world policy <u>sim</u>ulation (DWOPSIM) model building framework. DWOPSIM, a set of DOS batch computer programs and spreadsheet templates, allows users to assemble globally consistent data sets into time series models. Such models are used for policy analysis, short-term forecasting, and long-term projections. Users choose equations and code the structure along with model parameters into spreadsheet templates. DWOPSIM provides computer programs for the generation of model equations, the calculation of constant terms, the assembly of spreadsheet components into a linked global model, and the generation of simulation output.

Keywords: Agricultural trade, DWOPSIM, forecasting model, projections model, trade, trade model, world trade model.

Acknowledgments

I would like to thank Steve Haley and John Sullivan for their helpful review. comments and Bonnie Moore for her editorial help.

Documentation of the <u>Dynamic Wo</u>rld <u>Policy</u> <u>Sim</u>ulation (DWOPSIM) Model Building Framework

Vernon Oley Roningen

Introduction

This report documents the <u>dynamic world policy sim</u>ulation (DWOPSIM) model building framework. DWOPSIM allows the user to construct global multiproduct, multicountry time series models and solve them in spreadsheets. The framework is a set of DOS batch computer programs and spreadsheet templates that help a user with various tasks needed to build time series models, including the generation of model equations from a model specification coding scheme, the calculation of constants/intercepts for equations for a base period, the assembly of product and country spreadsheets into a linked world model, and the generation of simulation output. The framework also includes routines that construct globally consistent supply and utilization tables from a TSView database. The use of the DWOPSIM framework is illustrated with a small two-product, three-region world model that forecasts/projects variable values from the present to the year 2020.

The report begins with an overview of the DWOPSIM model building framework and a flowchart summarizing the model building process. This is followed by a discussion of data preparation, including a description of DWOPSIM programs. Next, the process of specifying model equations and entering their parameters into DWOPSIM equation spreadsheets is explained. The entry of exogenous data into product, country, and world spreadsheets is then discussed. Procedures for product model initialization and world model assembly are illustrated. Finally, model simulation and output generation are discussed.

The DWOPSIM framework is illustrated with a small global time series model named TIME. Appendices describe the TSView database used for the demonstration model and provide sample documentation of the demonstration model TIME. DWOPSIM computer programs are also documented in an appendix.

Overview of the DWOPSIM Model Building Framework

While static global models are useful and practical for global policy analysis $(\underline{1}, \underline{6})$ and projections $(\underline{5})$, there are also good reasons to use models that show the time path of variables under various simulation scenarios.¹ For example, an analyst might want to do short-term forecasting or long-term projections. Dynamic considerations represented by lagged variables might be considered important in certain modeling situations. From a technical viewpoint, it is more difficult to create well-behaved dynamic time series models than static models. Data requirements for time series models are greater, and dynamic properties may cause solution problems for such models ($\underline{4}$). Just as spreadsheets have proved to be a practical vehicle for the construction of global static models, the DWOPSIM spreadsheet modeling framework can provide similar advantages for dynamic time series-based models.

¹Underscored numbers in parentheses refer to items cited in the References section.

Experience with the static world policy simulation (SWOPSIM) modeling framework ($\underline{6}$) led to the DWOPSIM framework, which allows for dynamic time series modeling but retains the spreadsheet as the modeling vehicle. In the static SWOPSIM modeling framework, a premium was put on a standard simple economic structure that allowed much of the routine model building and assembly work to be done by computer programs operating on spreadsheets. Dynamic modeling requires many more choices to be made regarding model specification. Therefore, DWOPSIM was designed to allow the user full discretion in model specification and parameterization, while retaining the convenience and user accessibility of spreadsheets.² In addition, given the existence of consistent global data sets available with USDA's TSView database system ($\underline{2}$), the DWOPSIM framework includes an option that allows the user to construct a globally consistent supply and utilization data set for products to be modeled. DWOPSIM uses the SuperCalc 5 spreadsheet.³

DWOPSIM model components reside in spreadsheets. Organization of the model structure in spreadsheets is entirely up to the user. Because the demonstration model TIME is based on a TSView product data set that is organized by product, each product in TIME resides in a separate spreadsheet for each country. Each country in TIME was given a separate spreadsheet for country specific data. Finally, a world model requires a spreadsheet for containing world reference prices and any other global data needed. Figure 1 shows the DWOPSIM data structure selected for the demonstration model TIME used in this report. Following the country and product nomenclature from the TSView data source (\mathcal{I}), the model TIME divides the world into three countries/regions, the United States (US), the European Community-12 (EC), and the rest of the world (RW). Two products are modeled, beef and veal (BF) and corn (CN). The model TIME is organized into six product/country spreadsheets, Typical linkages

between spreadsheets via model equations are shown with lines and arrows.

The construction of a DWOPSIM model consists of the assembly of data and the coding of the equation structure and parameters in the Figure 1--Organization structure of spreadsheets for the demonstration model TIME

²This is different from the SWOPSIM modeling strategy where a simple standard specification was used and built into the SWOPSIM framework. In contrast, DWOPSIM models require the user to provide all of the structure, specification, and parameters for model equations. The user can choose the spreadsheet structure for the model. The demonstration model TIME is organized with one spreadsheet per product; however, alternative organizational schemes are possible.

³SuperCalc is a registered trademark of Computer Associates International Inc., 1240 McKay Drive, San Jose, CA 95131, 408-432-1727.

appropriate spreadsheets, the writing of model equations in spreadsheets from the specification codes, the initialization of equations to base period data by the calculation of constant terms, and the creation of a global model by linking the spreadsheets in memory.⁴ Much of this construction is carried out by DWOPSIM programs. The updating of data or parameters simply requires a repetition of DWOPSIM operations after manual changes have been made in spreadsheets. The model-building flowchart on the following page summarizes the operations required to build and maintain/update a DWOPSIM model.

The first task in creating a DWOPSIM model is to assemble globally consistent data sets for the products and countries to be modeled in a chosen spreadsheet layout. This task can be done manually. But, if agricultural products from U.S. Department of Agriculture's (USDA), Foreign Agricultural Service (FAS) data are being modeled, the framework provides a set of programs that allow the user to easily prepare a set of quantity supply and utilization data from a SWOPSIM version of USDA's TSView product data ($\underline{7}$). Given that the user selects a product from the TSView data set, programs automatically generate a product spreadsheet for each country in a model.⁵ This step is accomplished by the program DWOPTIME shown in a box at the top of the flowchart. As with SWOPSIM models, each DWOPSIM model requires a rest-of-the-world region to close world markets for the selected product. DWOPSIM programs adjust data for the closure region (RW) to maintain world identities of zero net trade and balanced world supply and demand in each historical period.

The DWOPSIM model builder must specify and parameterize model equations. This is done by coding in the equation structure and parameters into a specific equation spreadsheet. The user is free to specify any equation structure and must rely on external analysis for equation parameters. In the demonstration model, TIME shown in the flowchart, spreadsheets containing equation codes and equations are organized by product with one country per product sheet.

Once spreadsheets have been created for all products and countries and the associated equation spreadsheets have been coded, the user must add exogenous data required by the model specification. In the example TIME, product-specific data goes into the product (such as USBF) spreadsheet, while country-specific data goes into the country spreadsheet (such as US). In addition, world reference price data must be put into world reference price spreadsheet (WD). Next, the program DWOPINIT is used to initialize the model spreadsheets. This means that information in the equation specification spreadsheet on equation form and parameters is used to write equations and initialize each equation to base period data. When the process has been completed for each spreadsheet, the user is ready to assemble a world model.

⁴Linkages between spreadsheets occur via SuperCalc 5's capacity to reference other spreadsheets in spreadsheet equations. When linked spreadsheets are loaded into memory, these linkages operate as a set of simultaneous equations reaching across spreadsheets.

⁵In the example of the model TIME in figure 1, DWOPSIM programs would create the spreadsheets USBF, ECBF, and RWBF where world net trade for BF would sum to zero. A second operation would create similar data spreadsheets containing supply and utilization data for CN. This is accomplished by the program DWOPTIME, which has been created and customized for this operation for the model TIME.

DWOPSIM Model Building Flowchart

(the model <u>TIME</u> with a product-based spreadsheet structure used as an example)

Step 1--ASSEMBLE GLOBAL DATA SET (illustrated by the model TIME, which uses a product spreadsheet organization)

Ψ,

...

The assembly of a world model for simulation is done by the DWOPSIM program DWOPSOLV. The equation portion of product and country spreadsheets is loaded into computer memory along with a world price equilibrium mechanism. When a year's (or years') data are not in balance due to policy or other economic shocks entered into the model, the set of spreadsheets with cross-product and cross-country linkages can be solved in memory to achieve zero world net trade in each simulation period. The solution values of the spreadsheets can be saved and compared with historical/baseline data.

In addition to the DWOPSIM routines mentioned above, various utility programs are available to the user for various tasks, such as printing data and equations. DWOPSIM programs are DOS batch programs that write and execute macros that operate on spreadsheet templates. The casual DWOPSIM user must have some knowledge of DOS and familiarity with SuperCalc 5 spreadsheet commands. However, the mechanics behind DWOPSIM programs are fairly simple. The ambitious user who knows DOS batch programming and SuperCalc 5 macrocommands can easily create DWOPSIM-like routines for his own purposes.

Because dynamic models are more complex and can be specified in many ways, DWOPSIM leaves specification questions largely up to the model builder. The demonstration model (TIME) used to illustrated the DWOPSIM framework builds upon the simple specification and parameters for BF and CN found in the US, EC, and RW model components of the SWOPSIM model DEMO described in SWOPSIM documentation (<u>6</u>). The product-based organization of TIME follows from the product organization of TSView supply and utilization data, but other model organization schemes are possible. Dynamic models typically require more data and parameters than static ones, especially if lag structures are involved. Therefore, questions of model size and computational efficiency become relatively more important for dynamic models than for static models.

Computer Requirements

The technical computer limit for the size of DWOPSIM models is the expanded memory available for holding SuperCalc 5 spreadsheet(s). In addition, SuperCalc 5 has a limit of 255 linked spreadsheets in memory at one time.⁶ This means that a microcomputer with a large memory should be able to handle a large model. However, the user is always cautioned by the rule, "big models can be big trouble." Large models are typically slower to solve and more difficult to interpret; thus, there may be "practical" limits to model size that might be reached even if technical computer limitations are not breached. SuperCalc 5 spreadsheet defaults must be set correctly. This can be done automatically by typing in the program name DWOPSIM and by following the directions on the screen.

⁶The model TIME used to illustrate DWOPSIM in this report consists of two products (BF and CN) and three regions (US, EC, and RW). This gives 2 x 3 = 6 product/country spreadsheets and one world reference price/solution mechanism spreadsheet, for a total of seven spreadsheets that will have to be kept simultaneously in memory in a linked mode. Three country/region spreadsheets contain only exogenous data so they do not have to be kept in memory. If another organizational scheme was used, such as a country one (where all product data for a country is on one spreadsheet), only four spreadsheets would have to be kept in memory.

÷.,

The current version of DWOPSIM does have practical limits built into it. For example, the equation-writing program (a spreadsheet itself) allows only 28 variables per model spreadsheet, variable lags of up to 9 periods, and a data (annual) range from 1960 to 2020. These "design" limits could be exceeded with bothersome changes in existing DWOPSIM programs and accompanying spreadsheet templates. These limits are partially based on practical matters, such as a desire to limit model printouts to two pages. Default printouts of DWOPSIM output are dependent upon the capability of laser printers to produce small print so that a lot of information can fit on a page. However, DWOPSIM programs also have the option to print to a disk file so that other programs can "fit" the data to paper.⁷

The programs which take data from the TSView system assume that TSView files are on the E: disk. However, the controlling batch software can be changed for another disk configuration. TSView data are organized as described in appendix 1. TSView data sets with different organization and product structures could also be used, provided that some programming was done to develop suitable two-letter country and product codes (which are required for DWOPSIM equation-writing programs).

Most DWOPSIM programs are applicable to all models, but a few key ones must be constructed for EACH specific model (for example, the programs with <u>TIME</u> included in their name in the model-building flowchart). When the user creates new models, one way of supplying the "model" specific programs and spreadsheet templates is to copy them from the model TIME to a new model name and edit them manually. The DWOPSIM program TIMEREPL (screen 1) gets the user started in this

direction by copying the necessary files to the D: drive and renaming them with the new model name. Model configuration and nomenclature in this report (that is, country and product codes) follow those used in the TSView database for SWOPSIM models. DWOPSIM batch programs (with the first four letters of their name being DWOP) are housed in the C:\BATCH subdirectory.

	These include DWOPNAME BAT NAMERW SUB NAMESOLV DAT
	WDS.CAL (which must be customized for products in NAME).
COMMAND	TIMEREPL NAME

⁷Small print is obtained on laser printers in DWOPSIM output programs by invoking Laser Control software. Laser Control is a registered trademark of Insight Development Corporation. Printouts of ASCII files on disk can be obtained in various sizes and configurations of print by the SIDEWAYS program, which comes with the SuperCalc 5 spreadsheet package.

Batch programs specific to the demonstration model TIME (first four letters of their name being TIME) are also housed in the C:\BATCH subdirectory. DWOPSIM programs are kept in the C:\DWOPSIM subdirectory, while spreadsheets and other files for the model TIME are kept in the C:\TIME subdirectory. In contrast to SWOPSIM, DWOPSIM file names do not contain the model name. As was the case with SWOPSIM, DWOPSIM programs leave their results on the D: drive where they must be manually copied to the model subdirectory for permanent safekeeping.

DWOPSIM programs all have explanatory screens (such as screen 1), which can be invoked by typing the program name (use capital letters) without the parameters required by the program. Error traps have been built into the programs to alert the user if file preparation steps have been omitted.

Assembly of Globally Consistent Quantity Data in Model Spreadsheets

The first step in creating a global trade model is the assembly of a consistent set of quantity data, including globally balanced trade data. This can be done manually by carefully entering data into spreadsheets. The number and organization of spreadsheet components of a model is up to the user. It should be kept in mind that a world market-clearing mechanism will have to be designed based on some principle. The model TIME does this by clearing world net trade for each product with a mechanism that changes world prices until net world trade equals zero.

The SWOPSIM modeling framework has routines that reformulate USDA's global FAS supply and utilization data into a TSView 143-country/region database.⁸ This database serves as the repository for product supply and utilization quantity data used to generate the product spreadsheet data for each country in the model TIME. The program DWOPTIME (screen 2) is created for the model TIME to automatically

Screen 2--The program DWOPTIME

	DWOPSIM Program to create TSView-based data for model TIME						
DWOPTIME REQUIREMENTS	Program to make a complete set of balanced supply and demand spreadsheets for a selected PRoduct from a TSView data set for each CountrY in the model TIME, including a globally balanced RW (Rest-of-World bal. with DWOPBLRW). A E:\TS subdirectory must contain the PRoduct TSVIEW files. A subtraction control file for TSView software must be on the model NAME subdirectory with the name NAMERW.SUB. An example of such a file for a three region world (US, EC, and RW) where RW = WD - US - EC might be:						
	TEMP.TS TEMP.TS 1 1 3 5 RW RW = WD-US-EC (Codes for TSView #s)						
OUTPUT (D:)	CYPR spreadsheets for each CountrY in TIME plus the globally balanced RWPR spreadsheet.

carry out the data retrieval operation. DWOPTIME not only gets data for the US and the EC and calculates data for RW (= World - US - EC), but it also performs an exercise on RW data to make sure the total world trade for all

⁸More information about the TSView database ($\underline{7}$) used for DWOPSIM is found in appendix 1, which lists the country and product codes.

three regions sums to zero and that world supply balances world demand in each historical year.⁹ The global-balancing criteria are found in the spreadsheet DWOPBLRW.CAL, which is used by DWOPTIME. Figure 2 shows what part of the USBF spreadsheet looks like after DWOPTIME is run. The spreadsheet output of DWOPTIME is formatted by the DWOPTEMP.CAL spreadsheet. This includes column titles (but not units) copied from the TSView database. A DOS batch program equivalent to DWOPTIME must be assembled for each new model. A convenient way of doing this is to

Figure 2--Part of USBF spreadsheet created by DWOPTIME

TIMEREPL (screen 1) with a new model name (with four letters or digits) and edit the new file in places that are bounded by "rem ***.." lines. For example, if a different model has five countries/regions instead of the three in TIME, extra lines will have to be added for the new countries.

invoke the program

DWOPTIME uses an ASCII file TIMERW.SUB, which also must be created for each new model. TIMERW.SUB is used by one of the TSView utility programs when RW data are derived by subtracting US and EC data from world (WD) data in the TSView database. This file, which defines the residual region RW for a model, must be properly created for each new model and saved on the model subdirectory. The full explanation of the format of TIMERW.SUB (fig. 3) is found in TSView documentation (2). Basically, this file causes TSView to subtract data for the

⁹TSView software contains a set of utilities that allows the user to manipulate TSView data and put it into spreadsheets. DWOPTIME and related programs make use of these TSView utilities.

US (TSView country #3) and the EC (country #5) from world data (TSView region #1). After DWOPTIME is run for a selected product, separate spreadsheets are left on drive D: for the product for each country designated in the DWOPTIME program. For example, when the command "DWOPTIME BF" is run for the product "beef and veal," the files USBF.CAL, ECBF.CAL and RWBF.CAL will be found on the D: drive. These files can then be edited and product-specific data can be added. The files must be manually copied to the TIME subdirectory for safekeeping and further use by the DWOPSIM modeling framework.

In addition to product/country files (such as USBF), country files (such as US) and a world reference price file (WD) with exogenous data also are required for the model TIME. Figures 4 and 5 show parts of these two files. Note in figure 5 that the current DWOPSIM spreadsheet format allows data to be simulated or projected up to the year 2020 (not all data are shown). Projects needing projections beyond this year would require an extensive reformatting of DWOPSIM template spreadsheets and some changes in DWOPSIM programs.

Once the basic data for the spreadsheets have been prepared, the next step is to define the model structure by specifying equations and adding equation parameters. This is done in an equation specification spreadsheet, which accompanies every model spreadsheet containing variables to be modeled. The center of any DWOPSIM model becomes pairs of spreadsheets. In the case of the demonstration model TIME, there is a pair of spreadsheets for each product for each country. One spreadsheet--which is called the <u>model spreadsheet</u>-contains data and equations that forecast or project the data into the future. The other spreadsheet--which we will call the equation specification, or just <u>equation spreadsheet</u>--contains the coding of equations and equation parameters

Equation Parameters and Specification in Equation Spreadsheets

In a model spreadsheet, values of variables for years beyond the base year will require either equations calculating the variable or exogenous data values. Each DWOPSIM model spreadsheet holding equations MUST have an accompanying equation (specification) spreadsheet. This key equation information is used by DWOPSIM programs to write the equations in the appropriate place in the model spreadsheet. For example, equations in the model spreadsheet USBF.CAL will be written from the coded information in the accompanying equation spreadsheet USBFEQ.CAL. Figure 6 shows part of the equation specification spreadsheet USBFEQ accompanying the spreadsheet USBF.¹⁰

The equation spreadsheet holds equation terms in cells for every variable requiring an equation in a model spreadsheet. Explanatory variables for equations are found in columns C through AN. These explanatory variables may be contained in the model spreadsheet itself, or they may be contained in other model spreadsheets. Variables calculated by equations are represented by variable names in rows 6 through 43 of column A. Looking at figure 6, rows 1 and 2 contain descriptive variable names and units, respectively, which are used for reference purposes only. Row 3 contains the key model variable names that are used by DWOPSIM programs. The variable names have a specific format "SSvVC" where SS is the name of the spreadsheet containing the variable, v is

Figure 6--Part of the USBFEQ.CAL equation spreadsheet for the model TIME

¹⁰Equation spreadsheet names take the name of the model spreadsheet appended with the suffix EQ. A listing of an equation spreadsheet for the model TIME can be found in appendix 2.

the general type of variable, and VC is a variable name code (see appendix 2 for a brief explanation of these codes). Row 4 contains the letter of the column in the model spreadsheet where the data for the variable resides. Cell B2 gives the row number in the model spreadsheet that contains the data to be used as the base year values for model initialization. The information in rows 3 and 4 is key to the operation of DWOPSIM model building programs.

Nomenclature conventions used in rows 3 and 4 of the equation spreadsheet must follow DWOPSIM conventions. The name of the model spreadsheet containing equations to be modeled (such as USBF) requires four letters. The name of the model spreadsheet MUST be located in cell Al (right justified) in the equation spreadsheet and the appendix EQ MUST be (left justified) in cell Bl. The name of the model spreadsheet containing a variable MUST be the first part of the variable name in row 3 of the equation spreadsheet. Model spreadsheets that have no equations (only exogenous data), must have a two-letter name (such as US).

An example can be given for BF production in column E of the equation spreadsheet USBFEQ.CAL (fig. 6). The variable is given the name USBFqPR, which means that the variable for the quantity (q) of beef production (PR) is found in column D of the model spreadsheet USBF (fig. 2). Column C, row 3 of USBFEQ.CAL in figure 6 gives the name USBFnSL for US beef slaughter numbers and row 4 says that this variable will be found in column B of the spreadsheet USBF.CAL.

The cells below row 5 of the equation spreadsheet contain the equation specification and parameters for the variable term (column) as it appears in the equation (row). The equation for a variable is simply the concatenation of all of the column terms in an equation row (the name of the variable to be explained by the equation is found in column A of the equation row). If a cell is blank, as is the case with many cells in the figure 6, this means that the variable represented by the cell column does not appear in the equation for the variable equation in that row. If the cell contains information, it contains a "v," which means that the variable in that column is to be used as an equation term with whatever arithmetic is found in the cell. For example, in figure 5, cell E7 contains the code "*v." This means that the product (*) of this variable (US beef production = USqPR) is to used as a term in the equation calculating the slaughter weight of US beef (BFrSW). An examination of the entire row of an equation for a variable will illustrate the idea for a full equation, but that requires a listing of all the terms making up an equation (see appendix 2).

Because the equation spreadsheet is so important, a special output program DWOPEOUT is available to print out all of the information in the spreadsheet in full in a readable format. Screen 3 shows the screen seen when the DWOPEOUT program is invoked.¹¹ Note that if the P (print) option is chosen, the program calls a batch program HPLASER, which sets a small print on an HP laser printer. The software Laser Control is used for printing the small print in this report for the model TIME. A file PORTSMAL set in the software

¹¹DWOPSIM program conventions follow those used in the SWOPSIM modeling framework. If a user is unsure of what a program does, typing the name of the program (without the model or variable names it asks for) will bring up the screen explaining the program. These screens, along with a full program listing for all programs, are found in appendix 3. Screen 3--The program DWOPEOUT

package defines the small print. If a user does not have this software, other laser printer control programs may do the job and their calling programs should replace HPLASER in DWOPSIM output programs. Alternatively, the user may select the F option, and print ASCII files to the D: drive. and use SIDEWAYS

or some other printing routine to print the results in a readable format.

Figure 7 gives part of this full printout for row 8 of the file USBFEQ.CAL (see fig. 6), which contains the equation terms for the variable BFqPR, the quantity of beef produced in the US. The bottom of figure 7 shows the full equation in terms of the variable names (partially shown in row 3 of figure 6). This full equation for the US for BFqPR used a standard equation notation, which is based on SuperCalc 5 mathematical operations notation (* = multiply, / = divide, ^ = exponentiation). In effect, when the blank cells are removed, the equation is a constant plus a string of the remaining cells in the row. The equation at the bottom of figure 7 also illustrates how lagged variables are marked in the equation spreadsheet. The first three terms in the equation are producer incentive prices (PI) found in the commodity spreadsheet USBF for the US. The first price term is the current price, while the second and third are lagged prices where the period of lag is indicated by an appended 1 or 2, respectively, to the explanatory variable name. The last term in the equation is a growth term where 0.0116 is the supply growth rate and WDeTM is the time trend variable found in the world (WD) spreadsheet. The constant term in an equation does not appear in the equation spreadsheet. It is calculated and placed in the actual equation in the model spreadsheet when the spreadsheet is initialized to base period data.

The specification shown in figure 7 also shows linkages to other model spreadsheets, specifically the US country spreadsheet (fig. 4) that contains real income (USeIN) and population (USePP), which are required as explanatory variables. A linkage to the USCN model spreadsheet also occurs where the consumer price for corn (USCNpCN) is required as an explanatory variable with a demand elasticity of -0.05. Finally, a linkage to the world (WD) reference price spreadsheet containing real prices (fig. 5) and time trend (TM) variable occurs via the variable WDeTM.

From a practical point of view, the lined printouts of the equation spreadsheets, printed by DWOPEOUT (as shown in appendix 2 for the model TIME), give all the information about equations in model spreadsheets. Furthermore, these printouts can serve as worksheets if equations are to be modified because it is easy to read equation terms handwritten on the printouts and the enter them into the equation spreadsheets. is totally maintained by the information inserted into the equation specification spreadsheet. DWOPSIM programs transform the equation spreadsheet information into actual equations in the model spreadsheets. This will be discussed later, but we must discuss policy and exogenous data first.

Policy and Exogenous Data in Model Spreadsheets

A model spreadsheet contains historical and projected data. It is the repository for historical data for a model. With current formatting, historical data can begin from 1960. While historical data are useful for econometric analysis, the only historical data absolutely required for simulation modeling are data with enough years to account for lagged variables required in an equation. Then, there are the variables to be explained into the future. This may be done with equations relating particular variables to other variables in the host model or other model spreadsheets. Projected variables may also be entered exogenously, or they may be calculated by equations (identities) manually entered into the spreadsheet. But, projected numbers are required for (exogenous) variables that are used in simulation equations; these numbers often are policy variables or exogenous data, from a modeling viewpoint. All of these data, no matter how they are generated, can be printed out by the program DWOPBOUT (screen 4). Again, if an HP laser printer is attached and the appropriate INSIGHT software is used, DWOPBOUT will print out a page of condensed print. If the "F" print to disk option is invoked, the user can obtain a print copy by some other means.

Figure 8 shows part of the data printout from the program DWOPBOUT for the model spreadsheet USBF from the DWOPSIM demonstration model TIME. Several points concerning prices, net trade, and policy price wedges can be illustrated with the data shown. Net trade is a variable generated with an "in spreadsheet" formula for both historical and future periods; net trade is an identity and does not require an explanatory equation with an intercept. This illustrates the point that formulas for variables not requiring constant terms can be put into spreadsheets manually. The other data in figure 8 do not exist in the model prior to 1989. But as long as simulations into the future for any variable do not require these variables (lagged) prior to 1989, simulation will be possible. Finally, some of the data are "policy" data, which are used to emulate policy changes over time. In the case of BFwCS, a consumer subsidy wedge, the numbers decline over time and are simply a base period number projected into the future with a deflation formula.

The flexibility of the spreadsheet enters into full force in these model spreadsheets. Spreadsheet formulas can be used to generate data if that is a desirable way to go. Data can be prepared externally to the model spreadsheets and can be entered manually or by user-designed programs.

In the case of identities that do not require constant terms, two options are available. Formulas can be entered manually into model spreadsheets, or they can be coded as equations in equation spreadsheets to be written into the model spreadsheets

Figure 8--Part of the model spreadsheet USBF

when they are initialized by the program DWOPINIT.

Once model spreadsheets contain historical data and any generated variables required for simulation past a model base period, the user is ready to initialize model spreadsheets. All of the required DWOPSIM operations for data preparation could be done manually. Alternatively, if an appropriate TSView supply and utilization database is available, DWOPSIM programs could automate some of the more difficult parts of data preparation. Exogenous projected data and derived variables will have to be entered manually.

Once data entry is completed, programs such as DWOPEOUT and DWOPBOUT¹² are available to print out compact readable versions of the model spreadsheets.

¹²DWOPEOUT also prints a page listing model spreadsheet variables and the equations contained in the spreadsheet using variable names found at the top of the equation spreadsheet. These "equations" (identical to the one seen at the bottom of figure 7 and listed in full for the model TIME in an appendix) serve as the mathematical documentation of a model.

Initialization of a Model Spreadsheet

Given a coding of equations structure and parameters in the equation spreadsheet, the next step is to have equations generated for years beyond the base period in the model spreadsheet. This converts the model spreadsheet from a data repository into a spreadsheet with equations explaining selected variables as a function of variables in the host and other model spreadsheets.

The program DWOPINIT writes equations and calculates intercepts (constant terms) that make the equations replicate base year data. Screen 5 shows the program DWOPINIT. Once the program has been run for a model (country and commodity, in case of the demonstration model TIME), it leaves the spreadsheet operated upon as well as spreadsheets linked to it by equations on the D: drive. These spreadsheets must be manually copied to the model subdirectory for permanent safekeeping.

The equations are written into the model spreadsheet in simple formula, using spreadsheet cell notation to refer to variables. The bottom line of figure 9 shows the formula appearing in cell D36 of the spreadsheet USBF that was written out by the DWOPINIT program. The first thing to notice about the equation is that variables are now cell references in the USBF spreadsheet or cell references in other spreadsheets (the cell reference then is preceded by the spreadsheet name and a "!" mark). For example, the term USCN!T36 refers to the variable in cell T36 of the spreadsheet USCN. The cross spreadsheet linkage capability

of SuperCalc 5 allows equations to include terms that are linkages to other spreadsheets. Also notice that the constant term is a number. This is calculated by the DWOPINIT program from the equation itself and the base period data (recall that the base period is selected in USBFEQ.CAL by marking the base period row in cell B2) and is inserted at the beginning of the equation. The arithmetic in the equation uses the notation of formulas in the SuperCalc 5 spreadsheet.

Every time a data number or equation structure or parameter is changed in a model spreadsheet for a country, DWOPINIT must be run to update the equations and recalculate the constant term. If there are many model spreadsheets for many products and countries, a batch program that loops through all the model spreadsheets containing equations calling DWOPINIT should be prepared. The demonstration program TIME has a batch program TIMELOOP that does this kind of looping operation.

Some model spreadsheets may contain only exogenous data and no equations need to be written. In this case, there will be no accompanying equation spreadsheet nor any need to run DWOPINIT. The country spreadsheets US, EC, and RW in the model TIME are examples of these "equation-less" spreadsheets.

Assembly of Model Spreadsheets Into a World Model Linked in Memory

When the model spreadsheets (such as product, country, and world spreadsheets in the demonstration model TIME) have all been prepared and initialized, the user runs the DWOPSIM program DWOPSOLV. This program, shown in screen 6, calls up the equation parts (as well as the required exogenous data in the model spreadsheets) and places them in computer memory. DWOPSOLV also gets the world reference price spreadsheet, adds a world market-clearing mechanism template, and places this new world spreadsheet into memory. This is done in a manner that maintains linkages across spreadsheets. When DWOPSOLV has completed model assembly, the screen will show a message telling the user to press "Enter" to gain control of the world model. At this point, the model is ready to solve. When "Enter" is pressed, the user will observe a split screen centered on parts of the world market solution and reference price spreadsheet. The cursor can be moved to observe different parts of the spreadsheet on the screen. Entering ";" will toggle the cursor between the two screen parts. The screen size has been set for zoom, which uses small

print to give a larger picture of action on the screen. The computer commands (CNTL+) or (CNTL-) will toggle through the spreadsheets held in memory. Note that when DWOPINIT is invoked, the user must enter a one-digit/letter code to mark the solution when it is saved with the ALT-S command. This gives the user markings for up to 36 solutions for one assembled world model.

Screen 6--Program DWOPSOLV to assemble a world model from individual model spreadsheets

	DWOPSIM World Model SOLVer Assembly Program
DWOPSOLV	Program to assemble a DWOPSIM world model in memory and prepare it for SOLVing. A macro is also created which can be used to save the results on D: after the model is solved. Type ALT-S to invoke the 'save' macro.
REQUIREMENTS	The model can be solved by an analysis of the NAME subdirectory. A DWOPSIM model spreadsheets in the NAME subdirectory. A 1 Digit letter or number must be selected to mark the solution value files saved on D: This program also requires that a model specific batch file has to have been created and saved on the batch subdirectory (under the name NAMESOLV.BAT). This file tells DWOPSOLV what
OUTPUT (D:)	model files comprise the global model to be assumpted. A WDS.CAL world solution mechanism file must have been created on the NAME subdirectory. Linked files in memory for the model NAME, ready for SOLVing. If the ALT-S macro is invoked after the model is solved, D: will contain solution value files appended with the selected Digit (e.g. if D=1 for USBF, file is USBF.S1).
COMMAND	DWOPSOLV NAME D

Simulation of a DWOPSIM World Model and the Reporting of Simulation Results

The top part of figure 10 shows the message telling the user to proceed, and the bottom part shows the screen the user sees when the world model is ready to be solved. At this point, the user may manually change exogenous or policy data to shock the model. This may be done, for example, by manually changing projected (baseline) values of policy variables or by changing intercept shift terms if they have been entered as equation variables. When preparation is done in the appropriate model spreadsheets in memory, the global system can be solved.

Once the recalculation command is issued (by pressing F9), the set of spreadsheets in

memory will solve simultaneously until world markets are cleared by the world marketclearing mechanism now added to the WD.CAL spreadsheet in memory. This solution mechanism has to be manually constructed prior to solution and saved in the model subdirectory as a WDS.CAL file. In the case of the demonstration model TIME, this mechanism changes world prices for BF and CN in all time periods following the base period until world trade equals zero for BF and CN in all time periods.

user can let it complete solution by itself or he may want to visually check net world trade figures for progress in moving toward zero. The solution mechanism shown for the demonstration model TIME does have damping factors that can be adjusted for each product to control the world reference price and net trade swings (see fig. 10). These parameters are found in the world market-clearing template with the name WDS.CAL associated with each model. The market-clearing mechanism for the model TIME itself is similar to that of SWOPSIM where world prices are changed depending upon world net trade balances. When world net trade is zero for all products, world prices do not change anymore and the model is solved.

When an acceptable solution has been reached, the user must type in "ALT-S" to execute a macro that saves the solution values for each component spreadsheet of the world model on the D: drive. This solution can be viewed at will and should be saved to the model subdirectory for safekeeping and later analysis. The solution spreadsheets are labeled with the spreadsheet name with an appendix, which is S followed by a number or digit marking the solution. This number or digit was entered when the program DWOPSOLV was invoked. Once the solution has been saved in memory, programs are available to examine the output.¹³

The program DWOPSOLV itself calls a model specific solution program that must be prepared for each model. In the case of the model TIME, this program on the batch subdirectory has the name TIMESOLV. As was the case with DWOPTIME, the program TIMESOLV can be edited to suit the coverage of a different DWOPSIM model. See appendix 3 for a listing of DWOPSOLV. DWOPSOLV also calls a program DWOPWDS, which adds the world market-clearing mechanism in the spreadsheet WDS.CAL to the WD.CAL world spreadsheet in memory.

If the user does not want to save the simulation, the normal SuperCalc 5 commands //SQ,Y will exit the model spreadsheets in memory. When either the solution has been saved on D: (by the ALT S command) or the world model has been exited (via

the //SQ,Y SuperCalc 5 sequence), the user has the option of obtaining OTHER solutions by running a model specific *AGAN program. In the case of the model TIME, this program is TIMEAGAN. It takes the model files that DWOPSOLV had prepared for

Screen 7--The program DWOPCVAR

COMMAND	DWOPCVAR NAME FILE C S1 S2 S3 S4					

¹³Imagination in examining, manipulating, and presenting output results is largely up to the model builder. Spreadsheets are a very good medium for this purpose because spreadsheet templates, which reach into solution and history/baseline spreadsheets, can be constructed to aid in this process.

simulation and saved on D: and re-installs them into memory for another solution scenario. This process can be continued indefinitely, depending on room for storage of the solution values.

Once simulation results have been saved, three programs are available to examine and report simulation results. Screen 7 shows the screen for the program DWOPCVAR, which compares variables for up to four solutions with historical/baseline data.

Part of the spreadsheet created by DWOPCVAR is shown in figure 11. This spreadsheet can be printed out by executing the macro shown at the bottom of the figure (use ALT-F5). The template spreadsheet DWOPCVAR.CAL on the C:\DWOPSIM subdirectory, formats the output data and graphics. Figure 12 shows the graphical output contained in the spreadsheet created by DWOPCVAR. Again, the format and contents of the graph are created in the template spreadsheet DWOPCVAR.CAL. This illustrates the general method of reporting results, which is to create small programs and templates to retrieve and create the desired output. Because the solutions and historic or baseline data are in spreadsheets, all forms of reports and graphics can easily be created by the user. This can include the conversion of SuperCalc 5 spreadsheet output into formats readable by other spreadsheets.¹⁴

In figure 12, the solution files have been marked by the digit "7" and the plot shows the projection of US beef production for history (1960-91) and the base projection and alternative solution "7" from 1992 to 2020. The C:\TIME subdirectory has a series of commodity files with labels USBF7, USCN7, etc., which contain the solution data. The "7" solution shows the value of US beef production when world markets have cleared, while the baseline is simply the trend value of production. Normal procedure would be to substitute a baseline figure created when world markets cleared and then do alternative scenarios from the "globally balanced" baseline.

Solution output can be printed in the same format as historical and baseline data with the program DWOPSOUT. The output is in exactly the same format as that produced by DWOPBOUT (see output of DWOPBOUT in fig. 8 and app. 2). Screen 8 shows the screen seen if DWOPSOUT program is executed without

¹⁴SuperCalc can output LOTUS spreadsheets as an option. LOTUS spreadsheets are readable by most spreadsheet programs and many graphics presentation packages such as Harvard Graphics.

Figure 12--Graphical output from DWOPCVAR

providing parameters for it. The printed data series for both DWOPSOUT and DWOPBOUT go from 1960 to 2005 in order to get everything on one page with reduced print. Of course, this option could be changed by changing parameters in the programs and relevant spreadsheet templates.

Another useful output routine, DWOPCSOL, is similar to DWOPCVAR. DWOPCSOL produces a spreadsheet and graph of up to four variables from a model solution spreadsheet. It is useful for looking at graphs of a set of variables, compared with history and baseline in a model spreadsheet. Screen 9 shows the screen seen when DWOPCSOL is invoked without any of the required parameters.

If DWOPSIM proves to be a practical

vehicle for baseline work, projections, and time series modeling, users will use the simple techniques of DWOPCVAR, DWOPSOUT, and DWOPCSOL to develop other output routines. All of these programs are simply DOS batch programs, which manipulate model spreadsheets and spreadsheet templates that format the output.

Concluding Comments

The building blocks of DWOPSIM are simple compared with those of SWOPSIM ($\underline{6}$). This is because the large issue of model specification for the DWOPSIM model

builder is not built into the DWOPSIM framework itself as was the case with SWOPSIM. This means that there are fewer programs and procedures to deal with, but it also means that the DWOPSIM user will have to cope with the unique and complex problems that come with building a solvable and wellbehaved time series model. Many of the DWOPSIM conventions were derived from

Screen 8--The program DWOPSOUT

	DWOPSIM Output Program
DWOPSOUT	Program to print a page of a DWOPsim Solution from a model
REQUIREMENTS	DWOPSIM model spreadsheet solution FILE on model subdirectory (NAME). The solution spreadsheet will have the suffix *.SD where D is 1 Digit solution marker. A spread model name (FILE) is assumed. The template file DWOPSOUT.CAL must be available on the SWOPSIM subdirectory. The print (P) option assumes an HPLASER batch program calling a PORTSM97 configuration file for the Laser Control
OUTPUT (D:)	program. Print 1 page file on D: (with P option) or on D: (with F option) and a FILESD.CAL on D:

formulated to use two-digit country and commodity codes (such as the SWOPSIM 1989 TSView database $(\underline{7})$), DWOPSIM programs are available to prepare globally balanced sets of supply and utilization data for products defined in the TSView database. This process creates DWOPSIM product spreadsheets similar to the TSView database format.

Other data (not from TSView) needed for modeling in a world model must be found and entered manually into appropriate spreadsheets. A world marketclearing mechanism must be created as well. The user is free to design the spreadsheet structure of a model, or the user can proceed by copying the scheme that is used in the demonstration model TIME.

The user chooses equation specification and must provide associated parameters for econometric work or other sources. Equation specification can be linear or nonlinear, and variables can be lagged up to 9 years. Equations in a model spreadsheet can refer to other variables in that spreadsheet or other spreadsheets. For each model spreadsheet requiring equations, the user must code the selected equation specification and parameters into the accompanying equation spreadsheet. When this is done, programs initialize the model spreadsheets by writing the equations and including their calculated constant terms, which make the equations replicate base period data.

Once the model spreadsheets are initialized, the DWOPSOLV program assembles all of them in memory to create a linked global model. The user then solves them simultaneously and saves the solution. Subsequent scenarios can be obtained by resolving the world model files that were prepared by DWOPSOLV. Programs are available to examine solution output from various perspectives.

The simple structure of DWOPSIM models and the fact that they are built and run in spreadsheets make it relatively easy for users to prepare their own methods of examining output and doing post-solution analysis.

Key information on model structure and the location of variables is found in the equation spreadsheets. The choice of where to locate variables (which columns of a spreadsheet) is largely up to the model builder. However, it is wise to be consistent across spreadsheets in order to simplify the preparation of the three DWOPSIM programs that must be customized for each model. Consistency is needed to simplify the preparation of the world market-clearing mechanism and to take advantage of programs that can manipulate TSView data.¹⁵

When the user is familiar with DWOPSIM, the printouts of data and equation specification and parameters by the programs DWOPBOUT and DWOPEOUT, will provide adequate model recordkeeping.

The model TIME used to illustrate DWOPSIM is a three-region, two-product world model that includes features showing the capability of DWOPSIM. These features include cross-commodity (and cross-spreadsheet) equation linkages, lagged variables in equations, and various equation forms, including both linear and nonlinear specifications. The user can view the equations in the TIME model equation spreadsheets.

DWOPSIM equations are efficiently written using spreadsheet cell references, but for exposition purposes they are printed out by the program DWOPEOUT using variable names. The creation of a DWOPSIM model with more spreadsheets than found in the demonstration model TIME involves the same principles illustrated with this small model.

Installation of the DWOPSIM framework is a simple matter. The disk containing the programs includes instructions and an installation program. The computer containing DWOPSIM has to be configured with a D: drive (use a virtual disk or the DOS ASSIGN command) and should have 4 MB of memory with software to make it usable by SuperCalc 5. The installation program will create the proper subdirectories. If the user has an HP laser printer, he should also install the HPLASER program on the disk according to the instructions. This will make it possible to print DWOPSIM output in small print.

Finally, experience with time series model building with DWOPSIM will generate new and better ways of doing things. Further developments might include the automatic, as opposed to manual, creation of model-specific programs, such as TIMESOLV. However, future steps such as this will depend upon experience gained with DWOPSIM. In model building, programming cannot get ahead of actual user needs. All users are encouraged to record their experiences with DWOPSIM and provide suggestions for improvement. In the end, time series modeling itself is the best teacher.

¹⁵In the case of the model TIME, the three programs were (1) DWOPTIME which was needed to assemble commodity spreadsheet data from TSView data, (2) TIMESOLV which was needed by DWOPSOLV in the world model assembly stage, and (3) TIMEAGAN which can be used for repeated solution scenarios once DWOPSOLV has been run.

Appendix 1--Overview of a TSView Database Used by DWOPSIM

The TSView system (2,7) is a database and file viewer system developed by the Economic Research Service (ERS) to house supply and utilization data for grains, oilseeds, and livestock products. TSView also allows the user to select data from a database and put it out in a form that is readable by spreadsheets. This and other capabilities of TSView can be automated with utility programs that come with the system. DWOPSIM DOS batch programs combine these utilities with spreadsheet macros and templates to automate the process of preparation of a globally balanced dataset for a set of countries in a model for a selected commodity. The DWOPSIM programs require that the TSView database use two-letter country and commodity codes and that the programs themselves must be keyed to the numerical position of a particular country in the TSView database. Then balanced supply and utilization data for world models with any mix of countries and commodities can be easily created.

The TSView database behind this report can be referred to as the DWOPSIM/SWOPSIM (DS) TSView database. The key codes for DWOPSIM users are the two-letter code for each country/region and two-letter product code for each commodity (or aggregate). These codes are used not only to access the DS database, but they are also used in DWOPSIM spreadsheet names created from the data and, therefore, in variable names themselves. If the user wishes to use different codes and still use the TSView database, the choice is to re-do the database or manually rename everything in model spreadsheets (including spreadsheet names) derived from the DS database.

This appendix lists the numerical and alphabetical codes for all the countries/regions in the FAS TSView database used by the Commodity Economics Division, ERS, and in the DS version of the TSView database that contains additional aggregate regions for the different global databases. As a result, there are 213 countries/regions in the intermediate version of the CED TSView database, from which we have selected the following list of 143 countries/regions for use in the DS global database.

A detailed listing of the countries/regions within each of the 25 additional aggregate regions (213 minus 189) is provided by numerical codes here and by name in the appendix for each global database where they appear. The rest-of-world region for each database is provided by subtraction. This illustrates that the rest-of-world region differs by database, but does not list exactly what countries/regions it contains, since it is also used as a trade-balancing region. For some SWOPSIM databases, the rest-of-world region is quite large.

For reference, a listing in numerical order, and by name, of the 189 countries/regions contained within the FAS PS&D database follows. Then commodities included in the DS database are listed. There are 47 commodities listed by name and two-letter alphabetical code, which are contained in the DS version of the TSView database. The first set listed is the standard 22commodity set used in most ERS SWOPSIM models, and includes four commodities that are calculated aggregates. Next are the seven additional commodities that are now routinely included in the SWOPSIM database "t" files, and are available in a form ready for incorporation into models. Finally, we list the 18 additional commodities available in the DS TSView database. Of these, 12 come from the 4 aggregate commodities in the standard 22-product (SWOPSIM) set, and 4 come from the 4 new aggregates that result when the 12 are removed from the original aggregates. The last two commodities result from the poultry meat being separated into turkey meat, and broiler and other meat.

The program TSSWOP calculates values for the ROW (Rest-Of-World) region of each world model by subtracting values for each FAS country from the FAS world value (FAS code = 1). The subtraction is done with a TSVIEW utility controlled by a DOS batch program. If the TS data files are updated, TSSWOP can be run again to recalculate the SWOPSIM intermediate database values.

Appendix 2--Documentation of the DWOPSIM Demonstration Model TIME

This appendix gives sample documentation for one model spreadsheet in TIME (USBF). The user can use DWOPSIM programs to print other spreadsheets (see fig. 1, page 2, which shows the spreadsheet structure of TIME). Documentation of the data in a model spreadsheet is printed out (or printed to disk) by the program DWOPBOUT. If a model spreadsheet contains equations, the program DWOPEOUT will print documentation of the equations.¹

Data documentation: The data in TIME are history for 1960-91 and projected to 2020. Although the model spreadsheets actually contain projected data up to 2020, DWOPBOUT prints data from 1960 to 2005. The structure of the model spreadsheets is part of the model design, and it is a matter of judgment of how large a spreadsheet is needed. The user can obtain full printouts of the model spreadsheets by using normal spreadsheet printing techniques.

Equation documentation: Documentation of the equations coded in the equation spreadsheet is the standard output of the DWOPEOUT program. DWOPEOUT produces three pages for each model equation spreadsheet. The first two pages are a matrix of cells in the spreadsheet. The rows contain information about terms in an equation; the name of the variable explained is on the left along with the letter of its home column in the model spreadsheet. Some rows have no names and no information in cells--these are just extra rows that might contain equation information in more complex models. The columns in the model equation spreadsheet represent the explanatory variables in the equations. If there is no variable name under a column, there is no explanatory variable in that column in the spreadsheet. If cells under a variable name are empty, that means that the column variable is not used in an equation represented by the cell row. When a cell has contents, notation in the cell gives the mathematical representation of how the column variable (represented by the "v") is included in the equation represented by the row. Parameters are also included in cells. For example, in many of the TIME model cells, one will see elasticities or other parameters as part of the cell notation. The bottom half of the second page (right side) gives some notes explaining the nomenclature used for variables in the model TIME.

The third page of the equation documentation gives a "readable" version of the equations themselves.² The top part of the page gives the variable codes and their descriptions, units, and home spreadsheet column. The bottom half of the page gives the equations themselves written using DWOPSIM variable nomenclature from the model TIME. The spacing of the variables and equations follows their row position in the equation spreadsheet. Variables explained by equations are marked by an "X". Other variables will be exogenous variables, formula driven identities, or variables from other spreadsheets.

¹Note that in printout of data from the model spreadsheets, cells of columns containing no data are marked by dots "." A more complex model could add variables in these columns. "N/A"s mark cells where data are "not available" for particular years. In the model TIME, this is the case with support information which exists for a shorter period than quantity data.

²This is useful because the equations in spreadsheet cells use only cell notation to designate variables. This is efficient for computation but makes it difficult to read the equations. This third page of the DWOPEOUT printout provides a "readable" version of equations for the convenience of the user.

Appendix 3--Annotated Listings of DWOPSIM Computer Programs

DWOPSIM computer programs and routines are relatively simple. When tasks require spreadsheet formats or data manipulations, spreadsheet templates are created. The C:\DWOPSIM subdirectory contains several spreadsheet templates, which are called and used by DOS batch programs, usually with the same name as the spreadsheet. Some spreadsheets are complex such as the one that actually writes DWOPSIM equations. But all programming, whether in DOS batch programs or in spreadsheets, is open to the user.

DOS batch programs control DWOPSIM operations and write spreadsheet macros. The listings that follow are the key DOS batch programs that make up DWOPSIM. In some cases, annotation has been added to the documentation already contained in the programs. The name of each batch program is highlighted in bold print. Almost all DWOPSIM DOS batch programs have explanatory screens. If the user does not know what a batch program does or what parameters it requires, typing the name of the program will bring up the explanatory screen. In the following pages, the material in the explanatory screens will be seen at the beginning of the batch programs, produced by ECHO commands on the left.

Most DWOPSIM programs apply to all models; the first four characters of their names are DWOP. However, three important DOS batch programs must be created for each model. For the model TIME, they have the names DWOPTIME, TIMESOLVE, and TIMEAGAN. These programs can be created for a new model by selective text editing of the programs associated with the model TIME. Certain parts of the batch programs and/or associated spreadsheets must conform with product and country codes in a new model. And lines must be added if the new model has more countries or commodities than the model TIME. The creation of these three "customized" batch program defines a new model much in the way that a new master model file defined a new model in SWOPSIM.

The first program to be created (DWOPTIME for the model TIME) tells DWOPSIM what country data to get from the TSView database for the world model. It also defines the rest-of-world region as the world minus the countries/regions explicitly defined in the model. When this program is run, the user gets a globally balanced set of commodity data for the commodity selected. Balanced means that rest-of-world data from the TSView database are adjusted so that world supply equals world demand, world net trade equals zero, and world imports equal world exports for every year in the historical data. The "balancing" rule is contained in a spreadsheet template DWOPBLRW.CAL. This spreadsheet has to be consistent with the data modeled. For example, in the model TIME, data include stock changes and, therefore, world balances must account for stock changes. The second program to be created (TIMESOLV) tells DWOPSIM what commodity spreadsheets need to be collected into memory to form a world model. The program is called by the generalized DWOPSOLV program. The third program is TIMEAGAN, which allows repeated scenario analysis once DWOPSOLV has been run.

All of the programs have error traps that stop the program and tell the user if some important spreadsheet or program or piece of entry information is missing. When a program successfully completes its task, the results are left on the D: drive. The user can inspect them, and if they are satisfactory, they must be manually saved to the model file. This feature, similar to that used in SWOPSIM, insures that programs producing errors will not destroy model information. But the user is advised always to have backup copies of model files available just in case mistakes are made.

 DWOPSIM - Dynamic WOrld Policy SIMulation model building framework DWOPSIM is a set of DOS batch computer programs and SuperCalc 5 spreadsheet templates that allow a user to assemble globally consistent data sets into time series models in spreadsheets. Such models, which have all of the convenience and user access associated with spreadsheets, can be used for policy analysis, short term forecasting, and long term projections. DWOPSIM models clear world trade markets through world price changes which are linked to product behavior in individual countries and regions. The user is free to choose model structure and equation specification. Complete documentation of DWOPSIM programs and an illustrative model named TIME is found in: Roningen, Vernon O., Documentation of the Dynamic World Policy Simulation (DWOPSIM) Model Building Framework, Staff Report No. AGES 9226, Econ. Res. Serv., U.S. Dept. Agr., Oct. 1992 (Call 1-800-999-6779 or 1-703-834-0125 from outside the U.S. or Canada for information on ordering the DWOPSIM documentation. 	ECHO DWOPTIME ECHOProgram to make a complete set of balanced supply and demand spreadsheets for a selected PRoduct from a TSView data set for each CountrY in the model TIME, including a globally balanced RW (Rest-of-World bal. with DWOPBLRW).ECHOglobally balanced RW (Rest-of-World bal. with DWOPBLRW). A E:\TS subdirectory must contain the PRoduct TSVIEW files. A subtraction control file for TSView software must be on the model NAME subdirectory with the name NAMERW.SUB.ECHOAn example of such a file for a 3 region world (US, EC, and RW) where RW = WD - US - EC might be:ECHOTEMP.TSECHOTEMP.TSECHORW1 3 5ECHORW1 3 5ECHOCYPR spreadsheets for each CountrY in TIME plus the globally balanced RWPR spreadsheet.

The regression programs DWOPTRND and DWOPOLSR are batch programs which call template spreadsheets and insert variables from a DWOPSIM model. The user must invoke the regression commands in the SuperCalc spreadsheet to do the calculations. The user also has to check to see that the ranges set for the regression variables are consistent with the number of observations of data as well as the number of explanatory variables used. In DWOPOLSR, the equation specification can be log or linear (controlled by a transformation code in DWOPOLSR).

Reports you can use . . . from ERS

U.S. Agricultural Trade Update gives you up-to-the-minute information.

Each month the U.S. Agricultural Trade Update brings you ERS' most up-to-the-minute data on the farm trade sector. This useful 6-page update brings you the most current figures, delivered by first-class mail to ensure timely delivery.

The U.S. Agricultural Trade Update covers the monthly farm trade balance, U.S. farm imports and exports by quantity and value, and leading exports and exporters.

A 1-year subscription to the *U.S. Agricultural Trade Update* costs just \$15. Or save by ordering a 2-year subscription (that's 24 issues) for \$29, or a 3-year subscription for \$42. Please add 10% for shipment to domestic addresses; 35% for shipment to foreign addresses (includes Canada).

Situation and Outlook Agricultural Trade Reports give you the facts . . . and the forecasts!

These reports provide both current intelligence and historical data on international food and agricultural developments. They also forecast how changes in conditions and policies around the world will affect both U.S. and international agriculture.

Outlook for U.S. Agricultural Exports offers the latest value and volume of U.S. farm exports, by commodity and region, as well as the agricultural trade balance, import commodities, and export outlook. Subscription includes 4 issues. *Agriculture and Trade* reports summarize the year's developments affecting U.S. agriculture and trade in five key regions, and look to the future with articles on market trends, trade, and policy (subscription includes 5 regional reports: USSR, China, Western Europe, Pacific Rim, and Asia.

The cost is just \$12 for a 1-year subscription per title. Or save by ordering a 2-year subscription for \$23, or a 3-year subscription for \$33. Please add 10% for shipment to domestic addresses; 35% for postage to foreign addresses (includes Canada).

Foreign Agricultural Trade of the United States gives you the latest information on U.S. markets.

This periodical updates the quantity and value of U.S. farm exports and imports, plus price trends. Its coverage of over 200 countries and more than 500 commodities will keep you informed of how U.S. trade stacks up in a global market. Subscription includes 6 issues plus calendar and fiscal year supplements.

The cost is just \$25 for a 1-year subscription. Or save by ordering a 2-year subscription for \$49, or a 3-year subscription for \$72. Please add 10% for shipment to domestic addresses; 35% for shipment to foreign addresses (includes Canada).

Order now! Rates good through 12/92.

Call our order desk toll free, 1-800-999-6779 in the U.S. and Canada (other areas, please call 703-834-0125). Or write: ERS-NASS, 341 Victory Drive, Herndon, VA 22070.

Back issues of ERS periodicals in prepackaged sets

Fill in your collection of ERS periodicals with packaged sets of our valuable data and analysis, now sale priced. While supplies last, ERS is offering sets of back issues of some of its major periodicals. Round out your personal collection of *Agricultural Outlook*, for example, with the complete set of issues from 1990 or 1991. Or find the historical data you need on farm income and expenses, production and efficiency statistics, and more with past years' issues of *Economic Indicators of the Farm Sector*.

It's easy! Just write ERS-NASS at 341 Victory Drive, Herndon, VA 22070, or call 1-800-999-6779 (in the U.S. and Canada; other areas call 703-834-0125) today.

And attention libraries: We offer an additional \$5 discount per periodical package to your institution. Just submit your order on letterhead, or on a purchase order with the pre-printed name and address of your library. Please note the discounted price in your order.

Agricultural Outlook '90. 11 issues; regular price if sold separately, \$88. Order # PKG-18. \$25.

Agricultural Outlook '91. 11 issues; regular price if sold separately, \$88. Order # PKG-19. \$25. (Sorry, 1989 Agricultural Outlook not available.)

Foreign Agricultural Trade of the United States, '89. 6 issues; regular price if sold separately, \$48. Order # PKG-20. \$20.
