### SUMMARY

In Cyprus, there is an oversupply of about 40,000 t of grapes which have to be disposed of at a loss each year usually in the form of arcohol. The scope of this study was to find atternative policies aiming at reducing the structural surpluses. Two policy options have been studied (a) replacement of vineyards in the non-traditional viticultural zones with additionality enterprises (b) permanent abandonment of vineyards. Financial analysis of the first policy option, with own labour cost excluded, showed that a combination of todast craps and avestock (sheep), olive trees and almond trees can replace mean productivity vinevaids. With over labour cost included, olive trees can replace either mean or high productivity vineyards, atmons (rees can replace mean productivity vineyards, but todder crops and livestock proved unproblebie in replacing vineyards. Economic analysis, however, showed that only office trees can replace mean or high productivity vineyards with labour valued at either zero or rull cost. Analysis of the second policy option showed that an amount of 00369-411/ha for the very low yield in the life O£4495-5749 ha for the highest yield level could be offerred to growers by the government one buy their right to produce. It appears that the above options either separately or together offer realistic alternatives in correcting the present holicin of subslights a sector which consumption

The persistent disequilibrium in the wine market

#### INTRODUCTION

There is a surplus production of grapes in Cyprus and each year substantial quantities of grapes have to be converted into zivania (49% raw grape alcohol) and raisins. Interventions are carried out by the Vine Products Commission (VPC) in the form of mirchases of zivania (3845 t, 1981/86 average) and raisins (3728 t black, 650 t sultana, 1981/86 average) directly from the growers and eau-de-viedo sin (70% alcohol) from the commercial wineries (2000 t. 1981/86 average). Purchases by the VPC, converted into fresh grape equivalent, account for 52,400 t or 25% of total production, which is the amount of grapes subject to intervention each year (Arbendix Table 1). Since the VPC markets alcohol and a loss it can be easily concluded that grapes used its production represent an undesirable surplus 38 800 t or 18.8% of total production). It should be noted that the concessions granted under the terms of the Customs Union Agreement with the European Economic Community (EEC, 1987) will only allow for disposal of about 25 percent of total is the production. Unless appropriate measures are tweet a surplus production of grapes of about 40,700 t will become a permanent feature of our agricultural economy.

against this background, it was felt necessary to stells the possibility of replacing high yielding, but ios suality sineyards, especially those lying outside the readitional viticultural zones, with other crop or Hyperock enterprises. These vineyards (about 5-6,000 has planted on relatively flat lands and fertile soils between 1969 and 1972 are partly responsible for the increased production in the 1980-85 period, and aggravate the already difficult situation with surpluses of low quality grapes. The farmers' decision to replace trees and fodders with vineyards was the outcome of (a) the system of subsidies favouring productive vineyards and (b) the stable and secure prices offered for grapes which were guaranteed by the government. It is ironic that these vineyards which have replaced crops like olive trees, carob trees, cereals and fodder crops are now being considered for replacement by these same crops and livestock.

worldwide is directly related to the slower increases in wine consumption compared to wine production. Consumption of wine in France and Italy, the two major wine EEC producing countries, has been This fall was not offset by increased falling. consumption in other member countries. Policy measures taken to limit grape production were (a) restrictions in planting wine grape vines in certain regions and on heavy lowlands and (b) massive vineyard pull-out programme and conversion to other commodities. Three categories of pull-out programmes can be distinguished: (a) temporary withdrawal (6-8 years), (b) permanent withdrawal and crop substitution and (c) permanent withdrawal without substitution. Vineyard pull-out programmes have not given the expected results because of productivity gains and declining consumption (Commission of European Communities, 1986; Colchester et al, 1985; Keehn, 1985). Thus after the accession of Spain and Portugal it is estimated that by 1991/92 there will be an increase of 6 million hl in the community surplus so about 15-20 million hl will have to be withdrawn from the market through distillation various measures. Recently, Commission proposed raising of the abandonment premiums by 20% to enhance abandonment. Since the abandonment of vines must not create additional surpluses in other agriculture sectors, i.e. milk, it is proposed to use the released land for nonagricultural purposes or for agricultural enterprises which do not present any danger for marketing balances (Commisscion of the European Communities, 1988). Latin America (Argentina and Chile) are also facing wine surpluses. Policy measures taken by Argentina to reduce surplus wine production have been a national and individual wine production quota (FAO, 1984). Chile permitted the marketing of wines with an alcoholic content of less than 11 degrees, the blending with imported wines and the offering on the market of beverages consisting of a mixture of grape wine with wine made from other fruit juices.

In North African countries (Algeria, Morocco, Tunisia) the viticultural sector is declining. Measures

taken for replanting and restructuring of the vineyards have not yet produced any results. Various bodies or commissions have been set up for either awarding appellation of origin status or taking other necessary measures to modernize and improve the viticultural sector.

The main objective of this study is to assess whether it is financially and economically feasible (a) to replace productive vineyards in the non-traditional low quality viticultural zones with other crop and/or livestock enterprises and (b) to abandon permanently a number without replacement.

### **METHODOLOGY**

Studies were undertaken between 1985 and 1986 to assess the consequences of alternative policy measures in dealing with surplus wine production in Cyprus. The methodology used is described below.

## Policy option 1. Replacement of vineyards in non-traditional zones by alternative enterprises

Two parallel investigations were carried out. First seventy-two wine-grape growers residing in nontraditional zones were interviewed. A simple questionnaire was used to inquire into farmers attitudes towards various aspects of the proposed policy. Secondly cash flows were prepared for almond and olive trees and livestock enterprises (Appendix Tables 2 to 11). These enterprises are considered as the most suitable replacement for rainfed vineyards. It was found that the productivity of replaced vineyards is 8.5 t/ha and 18.5 t/ha for the mean and high productivity groups respectively. Two models were considered for livestock enterprises, Model A (starting with 20 and expanding to 30 productive sheep per farm in a six year period) replacing 0.67 ha of vineyards with roughage and Model B (starting with 30 and expanding to 60 productive sheep per farm in a six year period) replacing 1.3 ha of vineyards with roughage (Panayiotou, 1989).

The cost-benefit method of analysis was used and the criterion for appraisal was the Internal Rate of Return (IRR).

### Policy option 2. Permanent abandonment of vineyards without replanting

This is essentially similar to buying out the right to produce grapes, it is a 'set aside' policy. The subset of data used refer to the non-traditional viticultural zones, i.e. Semi-mountain Paphos and part of Paphos Vines (Papachristodoulou and Papayiannis, 1988). It is assumed that growers will be willing to cease production of grapes if compensated fully for the future profits they will forego. The criterion used is the gross margin per ha for a period of 5 to 7 years (from grubbing up to the time when new olive or almond trees will come into production).

Compensation is estimated by discounting yearly gross margins per unit of area for 5 to 7 years plus the expenses for uprooting and clearing.

#### **RESULTS**

Policy option 1. Replacement of vineyards in non-traditional zones by alternative enterprises

#### (i) Growers' attitudes

Eighty six percent of the growers interviewed were of the opinion that there is no crop or livestock enterprise that could profitably replace vineyards. Of those who thought otherwise, 21% considered almond trees a feasible alternative, 17% olive trees and 62% livestock as possible replacements. Eighty percent of the growers were prepared to uproot vineyards yielding up to 7.5 t/ha compensated with C£1875/ha. For higher productivity vineyards, about 80% of the growers were asking C£7500/ha. The majority of the growers (92%) were willing to uproot 0.13 ha of vineyards, if that would alleviate the vine problem, provided they were paid C£1125-3750/ha as compensation.

Although the vast majority (93%) of the growers are share owners, 68% rent additional shares in order to secure the disposal of their produce. Hence, about 58% declare that they would rather deliver their grapes without shares at lower prices.

Growers are, in general, aware of the problem of overproduction. They suggest that government should find new markets, speed up the vine replanting programme that would improve wine quality and take measures for rural development.

#### (ii) Cash flow analysis

Cash-flow analysis per unit of area for almond and olive trees and by flock size for sheep showed the following results (Table 1).

From the growers point of view (financial analysis), almond trees can replace vineyards producing up to 8.5 t/ha, whether labour is included (IRR= 15.4%) or excluded (IRR=13.2%) from the cash flows. Olive trees are even better, since they can replace vineyards producing up to 18.5 t/ha of grapes, regardless of including (IRR=18.0%) or excluding labour (IRR=16.3%). However, neither of the options (Model A or B) of replacing vineyards by livestock (roughage and sheep) are profitable when labour is included. The fact, however, that the growers' first preference is to replace vineyards by livestock, indicates that they do not consider their own labour in deciding about the profitability of an enterprise. The farmers' second best choice (olives or almonds) is in agreement with the present cash flow analysis.

**Table 1**. Financial and economic analysis when replacing vineyards of varying productivity with livestock or rainfed almond and olive trees.

	Vii	neyards		Rate of Re	tum (IRR)	
Replacing vineyards	to be	e replaced	Financi	al	Econo	omic
with:	Area	Productivity	Labour		Labo	our
	(ha)		Included	Excluded	Included	Excluded
A. Livestock & roughage				Internal Rate	of Return (IRF	R)
Model A (20-30 sheep)	0.67	Mean	4.2	36.7	0.0	5.9
		High	0.0	15.6	0.0	0.0
Model B (30-60 sheep)	1.34	Mean	5.4	33.2	0.0	7.1
	<u>-</u>	High	0.0	13.1	0.0	0.0
B. Almond trees	1.00	Mean	15.4	13.2	7.8	8.5
		High	0.4	1.8	0.0	0.0
C. Olive trees	1.00	Mean	31.6	26.7	22.8	19.5
		High	18.0	16.3	12.8	12.4

From the national economy's point of view, (Table 1) replacement with almonds is marginally feasible but not livestock, because livestock feed is subsidised and without these subsidies production is uneconomic. Olives could beneficially replace even highly productive vineyards with or without labour. The advantage of olives is their import substitution and export potential.

### Policy option 2. Permanent abandonment of vineyards without replanting

Table 2 gives the discounted gross margins per ha for 5 to 7 years. The amount required for compensation is estimated at C£369-411 for the very low yield level (below 3 t/ha) to C£4495-5749 for the highest yield level (over 15 t/ha). In these amounts an allowance of C£225/ha was given to cover uprooting and clearing expenses. The estimated amount assumed to be paid by the government as compensation could be recovered in 7 to 23 years in terms of savings of vine subsidies, if the subsidization of viticulture continues unchanged.

Permanent abandonment of 4000 ha of vineyards and replacement of a further 1000 ha with rainfed crops and livestock.

By reducing the area of vineyards by 5000 ha it would be possible to reduce grape production by about 40000 t, which is estimated to be the annual surplus production (at current prices and levels of production). The 5000 ha would be made up of 2500 ha from the Vines Paphos zone producing about 24000 t of grapes, all vineyards in the Semimountain zone (1500 ha producing 12000 t of grapes) and 1000 ha of the nontraditional viticultural zones producing 4000 t (Table 1). About 4000 ha of vineyards are expected to be 'set aside'. The remaining area of 1000 ha of vineyards is expected to be replaced by roughage (50%) for livestock, and olive trees (30%) and almond trees (20%). These percentages have been decided on the basis of growers opinion, cash-flow profitability and on marketing prospects of incremental production.

Marketing prospects for olives. Present production of olives (10850 t average, 1984-87) hardly covers local consumption. Shortages are currently covered by imports of about 370 t of olives and 330 t of olive oil (average 1980-86, Papachristodoulou et al, 1987). Olive trees proposed to replace vineyards are rainfed and most of their production will go for olive oil. The expected production of 1800 t of olives in 15 years should yield 360 t of olive oil (converversion ratio 5:1). The production of olive

Table 2. Discounted gross margin by yield stratum.

ross marg	Discounted g	Gross margin	Mean yield	Observa tions	Yield strata
7 year	5 years	(C£/ha)	(t/ha)		( t/ha)
. 18	144	34	2.5	20	< 3
109	848	200	4.9	51	3-6
191	1480	349	7.5	57	6-9
274	2120	500	10.4	37	9 - 12
40€	3137	740	13.9	25	2-15
552	4269	1007	19.5	26	>15

oil could gradually cover present imports and any possible future increase in demand.

Marketing prospects for almonds. Almonds are grown mainly under rainfed conditions either in compact plantations or intermixed with other crops. They are also found scattered on uncultivated land. The area under almond trees is about 5000 ha (average 1984-86) with an average production of 2700 t (Papachristodoulou et al, 1987). Yearly production fluctuates widely depending on rainfall and spring temperatures. Cyprus is self-sufficient in almond production and exports yearly about 100 t, therefore the scope for expanding this crop is not very big. The additional 750 t of almonds expected to be produced in 15 years should not pose serious marketing problems.

Marketing prospects for sheep milk and meat. With the replacement of mean productivity vineyards and introduction of 20000 sheep, the expected additional production is 2500 t of milk and 280 t of meat. There is a ready market for this incremental production as Cyprus is not self-sufficient in these products.

This production of meat represents about 5.2% of the apparent consumption or about 6.4% of total production (about 27.4% of total imports). With regard to milk production, it represents about 1.6% of the apparent consumption (Papachristodoulou et al, 1987).

### **CONCLUSIONS**

Two alternative policies for the reduction of surpluses were examined. The main conclusions may be summarized as follows.

1. From the growers' point of view, and if labour is costless, a combination of fodder crops and livestock or olive trees, can replace mean or high productivity vineyards to yield a similar net farm income. Almond trees can produce similar returns to mean productivity vineyards.

However with labour cost included, only olive trees can provide similar returns to mean or high productivity vineyards. Almond trees can only substitute viably for mean productivity vineyards.

From the point of view of the general economy, only olive trees can make an equivalent contribution to GNP as mean or high productivity vineyards, whether labour is valued at zero or full cost.

2. An analysis of the implications of the permanent abandonment of vineyards without replanting showed that the government would have to give sufficient compensation to growers to leave them with the same income as they earn from their vines. These amounts are estimated at C£369-411/ha for the very low yield level to C£4495-5749/ha for the highest yield level and these amounts could be recovered in 7 to 23 years.

It would, therefore, appear that the above alternative policies taken separately or together would offer realistic alternatives to the government to correct the present policy of subsidizing a sector which produces surpluses.

### **ACKNOWLEDGEMENTS**

The authors wish to thank Messrs G.S. Panayiotou and Chr. Papayiannis for their constructive comments on this report. They also wish to thank the technical staff of the Agricultural Economics Section for computational assistance.
