SOCIOECONOMIC CHARACTERISTICS OF GROWING AND DECLINING NONMETROPOLITAN COUNTIES, 1970

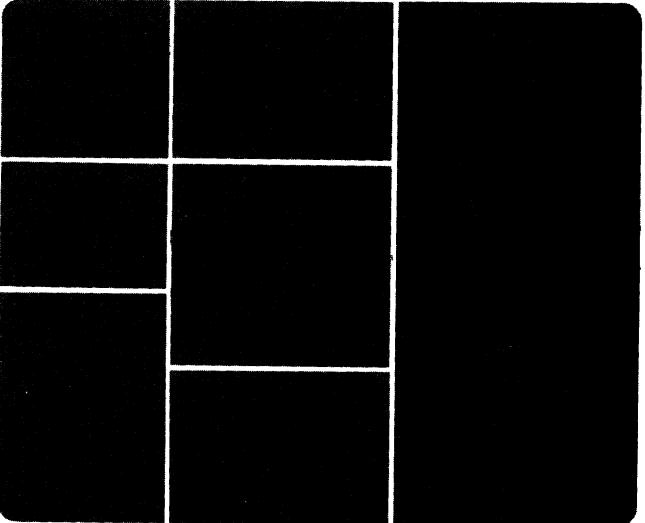

UNITED STATES DEPARTMENT OF AGRICULTURE
ECONOMIC RESEARCH SERVICE
AGRICULTURAL ECONOMIC REPORT NO. 306

ABSTRACT

Population decline can adversely affect an area's social and economic composition, its age structure, the structure of its labor force, and its ability to generate income to support essential programs and activities. Counties with declining population have a deficit of working age population and a relatively high proportion of dependent age groups. Declining counties trail the growing counties in family income, labor force participation by females, and employment in manufacturing; they are characterized by much higher than average employment in low-wage and low-skill extractive industries. A substantial number of counties that declined during the 1960's are currently experiencing population growth. Hence, population decline is not necessarily irreversible; not all declining areas are being bypassed by the process of national economic growth.

Key Words: Nonmetropolitan population, Population growth, Population decline, Socioeconomic characteristics, Age, Sex, Race, Education, Family income, Poverty, Occupation, Industry, Labor force.

SOCIOECONOMIC CHARACTERISTICS OF GROWING AND DECLINING NONMETROPOLITAN COUNTIES, 1970

**DAVID L. BROWN, SOCIOLOGIST
ECONOMIC DEVELOPMENT DIVISION
ECONOMIC RESEARCH SERVICE
U.S. DEPARTMENT OF AGRICULTURE
WASHINGTON, D.C. 20250**

AUGUST 1975

HIGHLIGHTS

Counties which are losing population lag behind population-gaining counties in family income, participation of women in the labor force, and employment in manufacturing. They also have higher than average employment in low-wage and low-skill extractive industries. While many of these population-losing counties have recently "turned around" and now experience population growth, population loss continues in others. Special assistance may be required to ensure a decent standard of living for residents of counties bypassed by national economic development.

Declining counties have a deficit of working age population, and a large proportion of elderly. Moreover, the racial minority population in declining areas has a relatively large proportion of young children as well. The youth and aged have relatively low rates of labor force participation and require a number of societal supports including educational and custodial institutions and health and income maintenance.

Median educational attainment of the racial minority population in rapidly declining counties (6.9 years) is 2 years less than that in counties that grew and experienced net immigration.

Regardless of race, region, or level of urbanization, the labor force participation rate of females in growing counties exceeds that in declining counties (37.9 percent vs 33.7 percent). Moreover, labor force participation is higher for women in counties that declined by less than 10 percent as compared with counties that declined by higher rates (34.7 percent vs 30.7 percent). In contrast, growing and declining counties differ only slightly in the proportion of males participating in the labor force.

Extractive industries such as agriculture and mining with relatively low wage and skill levels have experienced substantial declines in manpower needs; hence, counties highly dependent on extractive employment tend also to be areas of population decline. Employment in extractive industries increases regularly as a percentage of total employment as one moves from growing areas with net immigration (6.5 percent) to counties that lost 10 percent or more of their population (20.1 percent).

Growing counties have a higher proportion of their labor force employed in manufacturing than is true of declining counties (26.9 percent vs 23.1 percent), but the pattern is not regular over the four categories of growth and decline. The heaviest reliance on manufacturing employment is among those counties that experienced modest population growth or slight decline.

Median family income is substantially lower in declining counties as compared with growing counties (\$8,027 vs \$6,546). Moreover, rapidly declining counties have less than 70 percent as much income per family as do rapidly growing counties (\$8,331 vs \$5,741). Similarly, the percentage of families falling below the poverty line is higher in declining counties. Differences in family income are related to the industry mix of employment, labor force participation rate of women, age composition, and educational attainment--all these factors favor growing counties. Wages and salaries are somewhat more important as a source of income in growing counties while the opposite is true of social security and welfare.

CONTENTS

Data and Methods.....	1	
Patterns of Nonmetropolitan Population Change.....	8	
Analysis.....	8	
Counties with declining populations are generally compared with those with growing populations.		
Age and Sex Composition.....	8	
<u>Age</u> --higher proportion of children and elderly in counties with de- clining populations.....		8
<u>Sex</u> --females outnumber males in declining counties.....		11
Educational attainment.....	13	
The number of school years completed is generally lower in population-losing counties.		
Economic Activity.....	15	
<u>Labor force</u> --participation by women in the labor force generally less in de- clining counties.....		15
<u>White collar work</u> --the percent of white collar occupations is lower for counties with declining populations.....		16
<u>Employment by industry</u> --declining counties had larger proportion of labor force in extractive industries such as agriculture and mining.....		17
Family Income.....	19	
Median family income generally lower in declining counties; percent of poverty families higher.		
Conclusions.....	22	
For counties where population declines are ex- pected to continue, special assistance may be required to upgrade standards of living.		

SOCIOECONOMIC CHARACTERISTICS OF GROWING AND DECLINING NONMETROPOLITAN COUNTIES, 1970

by

David L. Brown, Sociologist
Economic Development Division
Economic Research Service

INTRODUCTION

Population change -- especially declines -- can have a serious negative impact on nonmetropolitan communities. Such change can adversely affect the composition of a community's population (5)*, and it is generally associated with the availability of services, amenities, and economic opportunities (6, 13).

Previous comparative research has investigated the association of population change with socioeconomic composition for cities and metropolitan areas (16, 20, 5) and for villages (12,7). Results of these studies are consistent; they show that growing communities have younger age structures, higher socioeconomic status, and higher labor force participation rates that suggest greater economic opportunity.

This study compares characteristics of growing and declining nonmetropolitan counties in 1970 (data are based on 1970 Census of Population, the latest source of such information). In addition, it provides separate analyses for whites and racial minorities, and for the South and nonsouth regions.

DATA AND METHODS

The units of observation in this research are nonmetropolitan counties and county equivalents.^{1/} Data were compiled from the 1970 Census of Population in which the characteristics discussed here are based on a 20-percent sample of all households. As these are sample items, there is concern over the reliability of the characteristics data for racial minorities in counties with

* Underscored numerals in parentheses refer to references on pages 25-26.

^{1/} The delineation of metropolitan and nonmetropolitan counties follows the official designation by the Office of Management and Budget in April 1974. Our data were compiled prior to the final announcement, however, and we recognize only 612 metropolitan counties rather than the current official total of 630.

very small minority populations.^{2/} For example, the racial minority data presented for a county with 250 minority residents are based on 50 actual cases. Hence, this analysis is limited to those counties having at least 250 racial minority residents. There are 1,308 such counties, about two-thirds of which are located in the South (table 1, fig. 1). Consequently, the analysis of national level nonmetropolitan data is heavily weighted by southern counties.

Since one purpose of this report is to describe the characteristics of both white and minority populations in growing and declining areas, the analysis is based, necessarily, on data collected in counties with at least a minimum minority population. This procedure raises the question of whether the socioeconomic differences between growing and declining nonmetropolitan counties with at least 250 racial minority residents reflect the more general differences existing between all growing and declining nonmetropolitan counties. Appendix B contains data for all 2,485 nonmetropolitan counties; they are highly similar to corresponding data presented in the text of the report. Readers interested in the socioeconomic differences between all growing and declining nonmetropolitan counties, regardless of race, are directed to Appendix B.

To delineate growing and declining counties, those growing by even one person [or that remained stable] were distinguished from those that declined. Table 2 indicates that regardless of the level of urbanization or of the region, the difference in the average rate of population change between the categories is approximately 20 percentage points.

Population change is a product of natural increase and net migration. In growing counties, population change was primarily due to natural increase, the excess of births over deaths, while net outmigration was the basic source of change in declining counties (table 3, fig. 2). However, growing counties did experience some net immigration. Table 1 indicates 306 of the 713 growing counties had net immigration while 407 experienced net outmigration. Furthermore, table 2 indicates that the rate of population growth is positively associated with net migration. Growing counties with net immigration grew by 22.5 percent while growing counties with net outmigration grew by only 6.3 percent. Consequently, growing counties were subdivided into two groups (a) those that experienced net immigration and (b) those that experienced net outmigration. Similarly, the declining category was partitioned into two groups, but since virtually all declining counties experienced net outmigration, they were divided on the basis of the rate of population decline. The distribution of

^{2/} Although several years old, 1970 Census Data are the most current available on socioeconomic characteristics at the county level. Racial minority refers to Negroes and other races. In the South, 96.7 percent of this category is Negro, but Negroes comprise only 81.1 percent of the racial minority population in the remainder of the country. Indians, Japanese, Chinese, Filipinos, and a number of other groups are major components of the racial minority population in the nonsouth (17). Of 1,308 nonmetropolitan counties with at least 250 racial minority residents, only 417 are located outside of the South. Consequently, the minority data are heavily weighted by the southern black population.

COMPONENTS OF POPULATION CHANGE FOR GROWING AND DECLINING NONMETROPOLITAN COUNTIES, 1960-1970

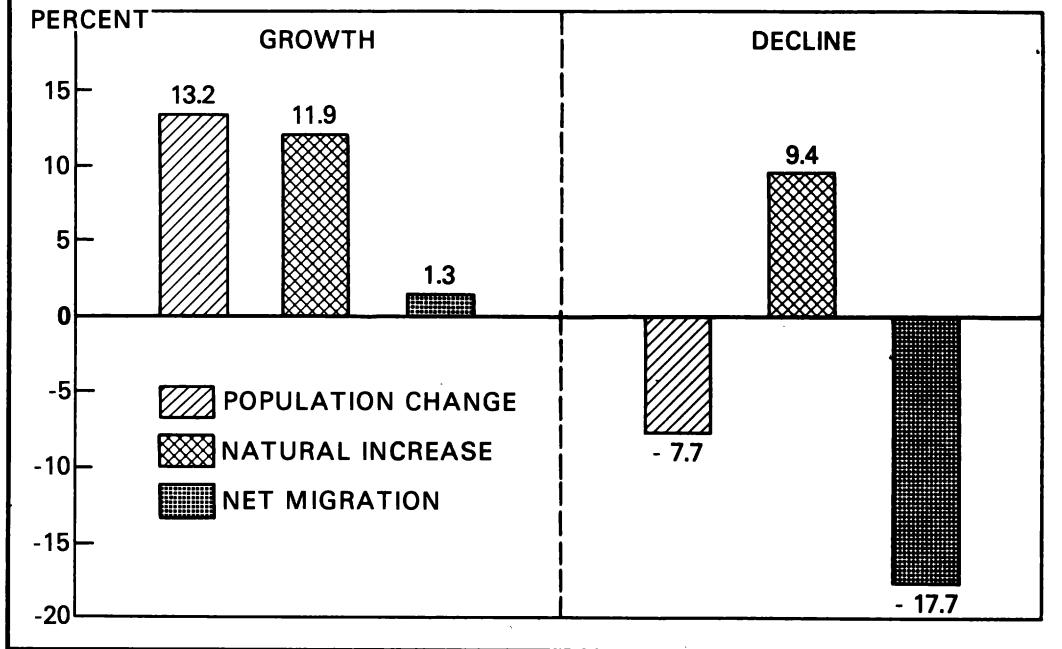

Figure 2

population and of counties over these four categories of growth and decline is indicated in table 1, and their rates of population change are displayed in table 2.

The level of urbanization is introduced as a test factor to elaborate the association between population change and population composition. This is necessary because previous research has demonstrated that population change and population composition bear a common association with urbanization (8). Thus, adjusting for the level of urbanization allows one to determine whether there is an actual link between population change and population composition, or whether the observed relationship is merely due to a common association with the third extraneous variable, level of urbanization.

Two urbanization categories were delineated by grouping together those counties having 20,000 or more urban residents and those having fewer than 20,000 urban residents.^{3/} This classification has been used in previous research which indicates that the categories are substantially different in their population characteristics (11).

^{3/} Urban residents are those living in places of 2,500 or more population.

This research focuses on socioeconomic differences between growing and declining nonmetropolitan populations, yet the data presented can be used to compare the composition of the various racial groups, regions, and urbanization categories as well. This analysis, however, is limited to the growth-decline comparisons, and the basic purpose for introducing race, region, and level of urbanization is to determine whether the differences between growing and declining areas persist after other factors are accounted for.

PATTERNS OF NONMETROPOLITAN POPULATION CHANGE

There are growing and declining nonmetropolitan counties in all parts of the Nation, yet definite areas of growth and decline are discernible as well. Figure 1 demonstrates that nonmetropolitan population growth took place in the interstitial zones between metropolitan areas of the Northeast and around the lower Great Lakes, in the Florida Peninsula and the Gulf Coast, the Southern Textile Piedmont, the mid-South uplands, the Ozark-Ouachita areas of Missouri, Arkansas and Oklahoma, and the far West. On the other hand, the Great Plains, Western Corn Belt, southern Appalachian coal fields, and cotton growing areas of the old South experienced decline in their nonmetropolitan populations.^{4/}

ANALYSIS

A socioeconomic profile of growing and declining nonmetropolitan counties is displayed in tables 4 through 8. These tables are composed of three sections: one for whites, one for racial minorities, and one for the total population. Moreover, each section is subdivided into control categories of urbanization. Identical tables for all 2,485 nonmetropolitan counties undifferentiated by race appear in Appendix B.

Age and Sex Composition

Age. The age composition of a community imposes requirements and limitations on each of its institutions. Figure 3 indicates that declining counties had a comparative deficit of young adults (aged 15 to 45) and a larger than average proportion of persons aged 45 and older. Hence, in 1970, the median age of growing counties (27.1 years) was lower than that in declining counties (29.0 years) (table 4). Similarly, growing counties were younger than declining counties in both categories of urbanization and in both the South and non-south regions (app. table A-1).

In contrast, the median age of the racial minority population was somewhat higher in growing than in declining counties (21.2 years vs 20.0 years). Figure 4 demonstrates that this is because there was a large proportion of young minority children, as well as of older adults in declining counties. Hence, the aging effect of the elderly was moderated by the large number of children, and

^{4/} Beale (2) has discussed these patterns more completely.

Table 4--Age and sex composition of growing and declining nonmetropolitan counties by race and level of urbanization, 1970 1/

Figure 4

the median age of the racial minority population in declining counties was reduced. The large number of minority children in declining counties is partly due to high fertility and the fact that a number of such children are left behind by parents migrating to metropolitan areas (18, 19).

Except for the larger proportion of racial minority children in declining areas, the shape of the white and minority age structures in growing and declining counties was essentially the same. For both racial groups, declining counties had a deficit of young adults and an abundance of older persons. This is reflected in the dependency ratio which, regardless of race, was higher in declining counties than in growing counties (table 4).

The dependency ratio is a crude measure of the relationship between the economically active population and those segments of the population which are economically dependent. Accordingly, declining areas had a heavier dependency load than growing areas, and because of their larger proportion of young children, racial minority populations in declining counties had the heaviest dependency load of all (table 4).

Dividing the growing counties by whether or not they had net inmigration reveals little difference in median age, yet figure 5 demonstrates that their age structures are substantially different. Growing counties with net outmigration had a high proportion of children and a deficit of young adults. This is reflected in the dependency ratio which was higher in growing counties experiencing a net loss of population through migration (84.9 vs 77.6).

Disaggregating the population decline category indicates that counties losing 10 percent of their population between 1960 and 1970 had a higher proportion of children, a substantial deficit of working age persons, and a slightly higher percentage of the elderly (fig. 6). Hence, the dependency ratio in such counties was notably higher than in counties which experienced a lesser degree of population decline (98.7 vs 89.1).

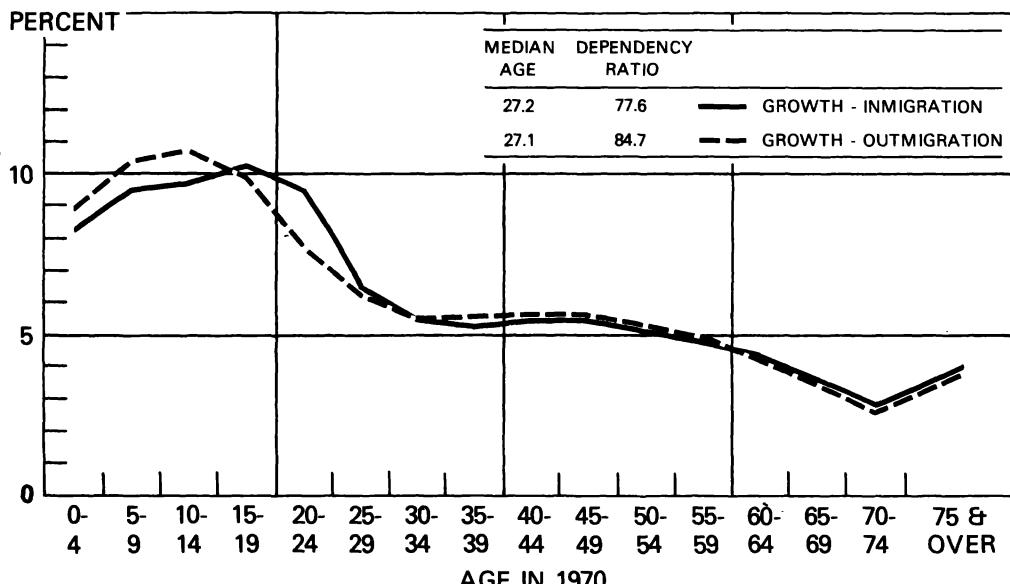

Sex. There were more males per 100 females in growing counties than in declining counties for both racial groups and within control levels of urbanization (although the difference is greater in those counties with 20,000 or more urban residents) (table 4).

Partitioning the growth and decline categories into their various components indicates that growing counties with net inmigration had more males per 100 females than growing counties that experienced net outmigration (99.3 vs 96.5). In contrast, there was little difference in the sex ratio between the two component groups of population decline (94.2 vs 94.1).

Sex differences between areas have generally been explained by the nature of employment opportunities, and areas with heavy employment in extractive industries have been shown to have high ratios of males to females. In the present data, declining counties had lower sex ratios than growing counties despite the fact that a larger proportion of their labor force was employed in extractive industries.

Accordingly, we must look elsewhere for an explanation of the present

Figure 6

findings. There is evidence that variation in the sex ratio between growing and declining counties is attributable to the disparity in length of life between males and females. That is, declining counties had a larger proportion of elderly persons, and male mortality is considerably higher than female mortality at these older ages (14). The sex selectivity of migration may be another contributing factor which explains the lower sex ratio observed in growing counties that lost through net migration.

Educational Attainment

At the national level, median years of schooling were higher in growing nonmetro counties (11.4 years vs 10.2 years), but this aggregate pattern was not characteristic of all race and regional categories. For example, the difference in educational attainment for whites was substantially reduced when the level of urbanization was adjusted (table 5). Regionally, in the South and nonsouth there was little difference in educational attainment for whites between growing and declining counties with 20,000 or more urban residents, although growing counties in the nonsouth did have higher educational attainment in less urbanized areas (app. table A-2). This suggests that differences in educational attainment for whites are due to urbanization rather than population change.

Racial minorities in growing counties had higher levels of educational attainment than their counterparts in declining counties. In the South, this difference was evident in both categories of urbanization, and in the nonsouth in more urbanized areas where educational attainment in growing counties exceeded that in declining counties by a full year (10.6 years vs 9.6 years) (app. table A-2).

Among growing counties, educational attainment was more than 6 months higher in counties that experienced net inmigration as compared with those that had a net migration loss. This difference holds for racial minorities in all counties, regardless of the level of urbanization, and for whites in less urbanized counties. There was little or no variation in educational attainment for whites between the county groups with 20,000 or more urban residents.

Declining counties losing 10 percent or more of their population had lower educational attainment than counties declining by less substantial rates. Once again, this comparison holds for racial minorities, regardless of the level of urbanization, and for whites in counties with less than 20,000 urban population. Furthermore, the patterns discussed above are generally characteristic of the South and nonsouth regions as well (app. table A-2).

For racial minorities, then, median educational attainment increased regularly as one moved from counties with heavy population decline (6.9 years) to those that grew and experienced net inmigration (8.9 years). For whites, the pattern was less regular, although educational attainment seemed to be associated with population growth in less urbanized counties.

Data from the Survey of Economic Opportunity indicate that black migrants have higher educational levels than nonmigrants, and hence, the differences in school years completed discussed above may be due to the loss through migration of better educated blacks from declining areas (1).

Another contributing factor may be age composition, since older populations as found in declining counties would tend to have lower educational status.

Economic Activity

Economic activity is a basic determinant of an area's prosperity and vitality, and community well-being depends, to a large extent, on the number of jobs available and the occupation and industry mix of the jobs.

Labor force participation. One aspect of an area's economy that is of fundamental importance is the proportion of its working age population (ages 14 and over) participating in the labor force. ^{5/} A county's labor force participation rate reflects the number and type of jobs available, economic pressure for more than one household member to earn income, attitudes toward work for women, and physical characteristics of the population such as age and health.

Regardless of race, region, and level of urbanization, the labor force participation rate of females in growing counties exceeded that in declining counties. This difference seems to be greater for racial minorities than for whites and especially greater for minorities in more urbanized counties (table 5).

There was little difference in female labor force participation for whites between counties that grew and had net inmigration and those that experienced net migration loss. In contrast, labor force participation was notably higher for racial minority females in growing counties with net inmigration. This difference is especially marked in southern counties (app. table A-2).

Comparing the two categories of population decline reveals a general inverse relation between the degree of population decline and labor force participation of women. Regardless of race and region, labor force participation was higher for women in counties that declined by less than 10 percent as compared with counties that declined by a more precipitous rate. ^{6/}

In contrast, growing and declining counties differed only slightly in the proportion of males participating in the labor force. Differences were very small and inconsistent for whites, and slight but consistently in favor of growing counties for racial minorities.

Disaggregating the population growth category reveals that regardless of race, region, or level of urbanization, growing counties with inmigration

^{5/} Persons in the labor force include both employed and unemployed (but looking for work) individuals aged 14 and older.

^{6/} There is no clear difference between the two groups of declining counties with 20,000 or more urban population, but there are only 10 such counties that lost 10 percent or more of their population. Hence, comparisons of these two categories are relatively unimportant.

tended to have lower labor force participation of males than was true of growing counties that experienced net outmigration (table 5). One explanation for this surprising finding is that many growing nonmetropolitan counties are centers for retirement and a larger proportion of older persons in a community would tend to reduce the overall labor force participation rate. Support for this explanation is demonstrated in figure 5 which showed that there was a higher proportion of the elderly in growing counties with net inmigration as compared with counties that grew but experienced net migration loss.

In addition, colleges and universities often create population growth with net inmigration, and college communities are likely to have a relatively large number of young adults not in the labor force. ^{7/}

Comparing the two categories of population decline indicates that male labor force participation was greater in counties that lost less than 10 percent of their population as compared with those that lost at a higher rate. Once again, there was little difference between more urbanized declining counties, but this comparison is weakened by the small number of counties in the high-decline group (table 1).

Percent employed in white collar occupations. At the national level, the percent employed in white collar occupations was higher in growing as compared with declining nonmetropolitan counties (37.4 percent vs 33.2 percent). ^{8/} This pattern was characteristic of both racial categories and of both levels of urbanization. Moreover, white collar employment tended to be higher, regardless of race or level of urbanization, in growing counties that experienced net inmigration as compared with those that lost population through outmigration. In contrast, there was no clear pattern of differences in the percent employed in white collar occupations between the two categories of population decline (table 5).

The pattern of differences discussed above was characteristic of the non-south regions as well as of the entire Nation, but not of the South. In the South, adjusting for race and level of urbanization substantially reduced differences in white collar employment between growing and declining counties. However, consistent with the pattern observed in other regions, growing counties with net inmigration did have a higher percentage of their labor force employed in white collar occupations than was true of growing counties with net outmigration (app. table A-2).

^{7/} Of 187 nonmetropolitan counties with 4-year State Colleges, 54 % grew with net inmigration, 28% grew with net outmigration, and 18% declined in population.

^{8/} White collar occupations include: (a) professional, technical, and kindred, (b) manager, official, proprietor, (c) clerical, and (d) sales.

Employment by industry. 9/ The types of jobs available in an area depend, to some extent, on the industrial composition of the area's economy. Hence, the differences in white collar employment discussed above may be associated with industrial composition. Most industries include a wide range of occupations, yet certain industries, such as agriculture and mining, have substantially lower skill levels than others. Agriculture, forestry, and mining have experienced substantial declines in their manpower needs, and hence, counties that have a large proportion of their labor force employed in extractive industries tend also to be areas of population decline. Regardless of race, region, or level of urbanization, declining counties had a larger proportion of their labor force employed in extractive industry than was true of growing counties (13.2 percent vs 7.4 percent) (table 6). Dependence on extractive industries increases consistently as one moves from growing counties with net inmigration to those that lost 10 percent or more of their population. In the South, whereas general differences between growing and declining areas applied, there was little consistent difference in extractive employment between the two subgroups of population growth. In addition, there seemed to be no difference in extractive employment for racial minorities between growing and declining counties outside of the South. However, when counties were broken into the four subgroups of growth and decline the familiar inverse relationship between population growth and percent employed in extractive industries emerged (app. table A-3).

Growing counties had a higher percent of their labor force employed in manufacturing than was true of declining counties (26.9 percent vs 23.1 percent) (table 6). This was the case in all race by region and level of urbanization categories. Growing counties that experienced outmigration had a somewhat higher percent employed in manufacturing than was the case for their counterparts that grew with net inmigration (28.8 percent vs 24.8 percent). One explanation for this is that manufacturing was not a rapidly growing industry during the 1960's, and counties that grew rapidly in population were not characterized by heavy employment in manufacturing. On the other hand, neither was manufacturing a declining industry. Hence, the heaviest reliance on manufacturing employment was found among those counties that experienced modest population growth or slight decline. Furthermore, counties that lost over 10 percent of their population during the 1960's had substantially lower employment in manufacturing than was true of counties that declined by less precipitous rates (25.4 percent vs 15.5 percent).

In contrast, there was little consistent association between population growth and decline and employment in wholesale and retail trade (table 6).

9/ The industrial categories are: (a) extractive--agriculture, forestry, fisheries, mining; (b) manufacturing--durable and nondurable; and (c) trade--wholesale or retail.

Table 6--Employment by industry of growing and declining nonmetropolitan counties by race and level of urbanization, 1970 ^{1/}

Family Income

Median family income was substantially lower in declining counties than in growing counties, regardless of race, region, or level of urbanization (table 7 and app. table 4). Comparing the four subgroups of population growth and decline indicated a regular increase in median family income as one moves from counties that lost 10 percent or more of their population to those that grew with net inmigration. The rapidly declining counties had less than 70 percent as much income per family as did the rapidly growing counties. This general pattern is characteristic of nearly all race by region and level of urbanization categories.^{10/} Similarly, the percentage of families falling below the poverty line was higher in declining counties as well. Differences in family income were generally greater for minorities than for whites and in the non-south rather than in the South.

Differences in family income may be related to the industrial composition of growing and declining counties. For example, Morrill and Wohlenberg (15) demonstrated that poverty was directly associated with the proportion of the labor force employed in such industries as agriculture and mining and inversely associated with employment in other industries such as durable goods manufacturing and trade. Consequently, if declining areas are characterized by low-wage and low-skill industries, then this might explain their lower level of family income. Moreover, income and occupational status are generally thought to be positively associated, and hence, another determinant of higher family income in growing counties may be higher occupational status (indicated by percent white collar).

Higher labor force participation of women in growing counties may indicate that such areas have a larger proportion of families with more than one wage earner. This is another factor that is likely to be associated with higher family income. Furthermore, differences in family income may be due to the sources from which income is accrued. For example, table 8 indicates that wages and salaries were somewhat more important as a source of income in growing as compared with declining counties while the opposite was true of social security and welfare. Such differences are especially marked for the racial minority population where 84 percent of all income came from wages and salaries in growing counties but only 78 percent in declining counties. Disaggregating the growth and decline categories revealed little consistent difference between the two subgroups of population growth. But, wages and salaries did make up a higher proportion of income in counties that lost less than 10 percent as compared with those that lost 10 percent or more of their population. Similarly, social security and welfare contributed a somewhat larger proportion of income in counties that experienced rapid population loss as compared with those that lost at less substantial rates. Finally, lower family income in declining counties is related to their higher ratio of dependent to working age groups.

^{10/} The general pattern is not characteristic of the white population in southern counties with 20,000 or more urban residents.

CONCLUSION

The composition of a community's population is associated with its current well-being and with its potential as a place to live. For example, the age and sex composition of a community imposes requirements and limitations on each of its institutions. Age-sex structure has implications for the size, rates of entry and departure, and other aspects of the labor force, for family formation and childbearing, for the demand for housing units, and for the delivery of community, health, and social services.

Although the differences between growing and declining counties were not generally large, the data in this paper depict a population profile in declining areas which is relatively less well off than that in growing areas. Moreover, most differences were not diminished by controlling for the level of urbanization, and in most cases, they held for both whites and racial minorities and in the South and nonsouth.

Paradoxically, many counties that declined in population between 1960 and 1970 experienced growth in the number of occupied housing units. In general, this is attributable to the reduced size of households in the United States.^{11/} For rural areas in particular, it is associated with the large number of elderly persons who continue to live in a separate household after their children have left home or after the loss of a spouse. This is an important consideration for a community because many services are distributed on a household basis rather than on a per capita basis. Hence, declining population has not necessarily meant a declining need for housing units or for fuel, water, and services associated with housing.

Perhaps the most important difference between growing and declining counties is the age composition of their populations. Declining counties were shown to have a deficit of working age population and a relatively high proportion of the elderly. Moreover, the racial minority population in declining counties was shown to have a surplus of young children as well. Youth and the elderly are generally thought of as being the dependent segments of a population. These groups have relatively low rates of labor force participation and they require a number of societal supports, including educational and custodial institutions and health and income maintenance. In addition, the availability of capital has been shown to be less in areas with heavy dependency burdens (4).

Declining counties were also shown to lag behind growing counties in family income, and it was suggested that this difference was related to lower levels of labor force participation by females and a higher proportion of the labor force employed in low-wage and low-skill extractive industries in declining counties.

^{11/} Average number of persons per household declined from 3.67 in 1960 to 2.97 in 1974 (U.S. Bureau of the Census, Decennial Censuses, and Current Population Reports).

These data seem to indicate a rather bleak future for nonmetropolitan counties that have experienced population decline, and especially for those that declined at a rate of 10 percent or more. Interestingly, however, a substantial number of counties that declined in the 1960's have "turned around" and are currently experiencing population growth. The data in table 9 indicate that 64 percent of the counties that declined during the sixties gained population between 1970 and 1973 (833 of 1,297), and that 53 percent of those that declined by 10 percent or more during the sixties gained between 1970 and 1973 (275 of 517).

This suggests that the determinants of nonmetropolitan population decline may be transitory, e.g., population decline may reflect a period of adjustment in the manpower needs of agriculture, forestry, mining, and other extractive industries. Recent population growth in such areas is indicative of growth in manufacturing, service, and other types of nonextractive employment (3). Hence, one cannot conclude that population decline is an irreversible process, and that all declining areas are being bypassed by the process of national economic growth.

In contrast, the data in table 9 also indicate that the vast majority of counties that lost population between 1970 and 1973, in fact, also lost during the 1960's (464 of 592). Thus, in many instances, population decline does tend to perpetuate itself. This tends to be the case in such areas as the Great Plains where decades of decline have created an age structure which is not conducive to natural increase, and in parts of the southern coastal plain and old cotton belt where the outmigration of racial minorities continues at a relatively high rate.

The process of national economic development spreads its gains and burdens inequitably among geographic, demographic, and economic groups. Many nonmetropolitan areas are characterized by population growth, while in others, population decline is a transitory adjustment to reduced manpower needs in extractive industry. For these areas, the social and economic future seems optimistic. For other areas, especially those that have experienced long-term continuous population decline, an optimistic future is not assured. Data presented in this report indicate that population decline can have a detrimental impact on the socioeconomic composition of an area, on its age structure, on the structure of its labor force, and on its ability to generate income to support essential programs and activities.

These communities present a paradox for public policy. As Hoover (10) has noted, one broad aim of population distribution policy is a rapid advancement of the Nation's per capita income. The realization of this objective would require that population and economic activity be located where they can contribute most effectively to national per capita output. Hence, the spatial misallocation of manpower and capital is clearly to be avoided.

Hoover suggested that a strategy of enhanced mobility (for both labor and capital) is the most fundamental way in which a government can influence spatial allocation with the aim of increasing national per capita output. Moreover, it follows that, in many instances, this strategy requires the migration of people and business from areas of low marginal productivity to areas of higher marginal productivity.

On the other hand, Heady (9) has observed, "...we want development for rural communities which possess positive possibilities... But for those who do not, we also have an equal obligation, if we are not to further the inequities which stem automatically from economic growth."

Accordingly, there is growing concern that, to prevent inequity, forms of assistance might be directed to those settlements where the economic future is in question. Such assistance might come in the form of education and training programs, public aid to ensure the provision of high quality health, recreation, and social services, or as payments to cover the capital loss suffered by businesses in declining areas. But basically, aid is needed to enhance standards of living for persons who live in communities bypassed by the process of national economic development.

ECONOMIC RESEARCH SERVICE
Economic Development Division

The Economic Research Service (ERS) develops information on a broad array of issues for decisionmakers at all levels--including members of Congress, USDA policy officials, State and local administrators, farmers and farm organizations, and consumers. ERS, through its Economic Development Division (EDD), provides information to help improve the conditions of rural life in the United States. It collects, analyzes, and publishes data on population, employment, incomes, farm and nonfarm workers, job skills, and education levels. It also evaluates changes in rural communities--schools, housing, medical services, and public facilities. Other recent EDD publications include:

- * Social and Economic Characteristics of the Population in Metro and Nonmetro Counties, 1970 (AER 272) by Fred K. Hines, David L. Brown, and John M. Zimmer.
- * State Programs for the Differential Assessment of Farm and Open Space Land (AER 256) by Thomas F. Hady and Ann Gordon Sibold.
- * American Indians in Transition (AER 283) by Helen W. Johnson.
- * Farm Real Estate Taxes: Recent Trends and Developments (RET 14) by Jerome Stam and Eleanor Courtney.
- * The Revival of Population Growth in Nonmetropolitan America (ERS 605) by Calvin L. Beale.

Single copies are free on request to Publication Services, Rm. 0054-S, ERS, U.S. Department of Agriculture, Washington, D.C. 20250.
