DEVELOPMENTS IN HUMAN NUTRITION

by

Ruth M. Leverton, Assistant Director
Human Nutrition Research Division

and

Faith Clark, Acting Director
Household Economics Research Division
Agricultural Research Service

The nature of the changes that have occurred in food consumption in this country over the past 20 years indicates that the recommendations of nutritionists have been an influence in improving the quality of the American diet. Today we will try to sum up what research is telling us about the nutrition situation in this country, and what the emphasis will be in our nutrition education programs that have implications for food production and marketing.

Periodic surveys of the food consumption of various population groups provide us with information we need to appraise dietary levels and to give guidance for nutrition education. The most recent nationwide survey made in 1955 gives us a fairly accurate picture of dietary levels in this country today. Results of this study indicate that the food supplies of families continue to be abundant, varied, and of high quality. If they were distributed strictly according to nutritional needs, every man, woman, and child could be well fed.

Considerable improvement in family diets has taken place in this country in the past several decades. In the 1930's when a large-scale dietary survey was made, a third of the diets was classed as "poor." Today in scarcely more than one-tenth of the households can diets be called "poor" by the standards used in the earlier period. Almost all of this improvement took place between the mid-thirties and the early postwar period.

This dietary improvement has been the result of a combination of several factors. Market supplies have been ample. We have enjoyed economic conditions under which an increasing proportion of people have been able to have the kinds of foods they want. We have had continuing emphasis on research and education in nutrition. The enrichment of bread and other grain products has also had a part in dietary improvement.

Need for dietary improvement

Despite the generally good picture of dietary adequacy, we still have much to do to bring the quality of all family diets up to recommended nutritional goals. The nutrients in shortest supply are calcium and ascorbic acid. At the time of the 1955 survey three out of ten families had food supplies that furnished less than the amounts of calcium recommended by the National Research Council. One out of four families had ascorbic acid intakes which were below the National Research Council allowance. From 15 to 20 percent of the households had below recommended levels in vitamin A, thiamine and riboflavin. A tenth or fewer had food furnishing less than recommended amounts of protein, iron, and niacin.

On the basis of these findings nutrition education will continue to stress that people should take more care to get enough calcium and ascorbic acid, especially, and also vitamin A, thiamine and riboflavin. In terms of foods, this will mean special emphasis on milk and cheese because they are good sources of calcium and riboflavin, on citrus fruit and tomatoes for ascorbic acid, and on the dark green and yellow vegetables for vitamin A. To increase the thiamine, there will be emphasis on meat, especially pork, whole grain and enriched cereals, dry beans and peas.

Thus the foods for which demand would be especially strengthened as a result of nutrition education are dairy products, excluding butter, and fruits and vegetables. Rough calculations from the 1955 survey indicate that if all those households with less than recommended amounts of calcium in their diets were to consume the recommended amounts, about 9 percent more milk would be needed by households than is now used. A similar calculation for ascorbic acid indicates that about 6 percent more fruits and vegetables would be consumed.

In addition to recommending the so-called "protective foods," and the value of a varied or balanced diet, nutritionists will stress the advisability of limiting the intake of total food energy to a person's need and thus avoiding excess body weight. They will also point out that nutritionally adequate diets can be obtained at different consumer cost levels and at levels requiring different amounts of agricultural resources. In general, however, protective foods are high-resource using foods.

Because few people in the United States are hungry the population in general cannot afford calorie-wise to increase its total food intake. Therefore, if people consumed more of some foods, such as dairy products and fruits and vegetables, then their consumption of some other foods would have to decline, unless they increased their physical activity. Fortunately, food sources of the nutrients now in short supply need not be high in calories.

There is a relationship between family income and the nutritional quality of the diets. This means that some families have economic limitations on the choices of foods they can make. Higher income, however, is no guarantee of nutritional adequacy. Many families with higher income have diets that fall short of recommended nutrient levels. In 1955 one out of four of the families in the highest income third of the Nation had diets in need of improvement in calcium; one out of six in ascorbic acid. This and other findings indicate the need for more effective education of individuals and of homemakers in family food management.

Convenience foods

We hear too much about the increased use of convenience foods--foods that take relatively little time to prepare at home--but the average family food budget is by no means made up entirely of such foods. We have estimated

that in 1955 about 28 percent of the total expense for food at home of city families went for a list of so-called convenience foods--foods with varying degrees of built-in maid service. Farm families as well as city families buy the common convenience foods often used for quick meals. Until more specifications are set for the composition of many of these products, there is the danger that the amount and nutritional quality of the food ingredients are being slighted and an undue portion of the money going to pay for service. With as much as 28 cents of each food dollar going for foods with built-in maid service, more attention will need to be given to standards which will insure that the food is supplying its share of the family's nutritional needs. Progress is being made in setting specification of composition for many such products.

Fat in household food supplies

The survey results offer considerable information on the amounts and kinds of fat brought into the home. Because of the widespread interest in fat these results will be discussed separately. The periodic food surveys made by the Department of Agriculture indicate that the proportion of fat in household food supplies has increased during the last 20 years. In 1936 only 38 percent of the calories in the household food supplies came from fat. In 1955, 44 percent of the calories were supplied by fat. This increase came chiefly from the greater consumption of meat, poultry, and fish and the smaller consumption of grain products and potatoes in 1955.

These figures for available fat do not include any deductions for food discarded in the kitchen or as plate waste. It is quite likely some fat is discarded. However, studies of the quantitative food intakes of many hundred adults of all ages indicate that the proportion of calories from fat in their self-chosen diets is usually as high as 40 to 42 percent.

It is important for us to realize that a large share of the fat in the United States diets enters the kitchen as part of other foods--foods which are not usually thought of primarily as sources of fat. In 1955, meats, poultry, and fish provided 27 percent of the total; milk and milk products (other than butter), eggs, baked goods, and nuts provided 33 percent; and only 40 percent of the total dietary fat was furnished by visible fats and oils, including bacon and salt pork.

The amount of fat available for consumption is higher in farm than city food supplies. Among city families it is higher in the diets of the rich than the poor. It tends to be higher in the West than in the Northeast. The sources of fat are somewhat different in the South from those in the other major regions of the United States. Less of the fat in Southern food supplies comes from dairy products and meat, poultry and fish, while the share from bacon and salt pork is much larger. Fats used for home baking, especially lard, are more important as sources of dietary fat in the South than in other regions.

Dietary fat and health

No present-day discussion of food and nutrition seems complete unless it includes a consideration of fat and its relation to health, the topic-of-the-year. Unfortunately, this topic has been subject to inaccurate, hastily-formed conclusions which have created confusion and even anxiety in the mind of the public. The presumed direct relation between the fat content of the American diet and the occurrence of certain kinds of heart disease and atherosclerosis (the deposits of fatty material along the inner lining of the walls of the arteries) is still in need of many supporting facts from scientifically conducted research.

The proven facts about fat can be discussed from the standpoint of:

1. What is known about the body's need for fat?
2. Why is there concern about the kinds and amounts of fat in our diets?
3. What sound recommendations can nutritionists make?

1) What is known about the body's need for fat?

Fats are an important kind of food for all of us. As well as adding variety and flavor to many foods, fats are carriers of vitamins A and D, concentrated sources of energy, and suppliers of substances called fatty acids which are essential for growth and health. Also, in the utilization of food-stuffs, fats spare protein so that protein is available to perform its specialized functions. Within the body, fat tissue is important for the support, protection, and insulation of vital organs and areas. The complicated role of fat in nutrition is just beginning to be recognized and much more needs to be learned about the amounts and kinds of fats required for optimum health. Perhaps it is well to remind ourselves that we do know that fat is a normal constituent of our food, and the body's use of fat for fuel is a normal process.

One substance of particular importance which occurs in some fats is linoleic acid. It is called an essential unsaturated fatty acid. (A fatty acid is part of a fat molecule.) This is needed for the performance of vital functions in the body, such as maintaining the skin in a healthy condition. There is the possibility that a deficiency of linoleic acid interferes with the body's normal use of fat and that the proportion of linoleic acid to the saturated fats in the diet is important. Because the body cannot manufacture it, linoleic acid must be supplied by the food we eat. Common foods which contain appreciable amounts of linoleic acid are the natural oils from corn, cottonseed, and soybean. Peanut oil and poultry fat have lower content, olive oil and pork fat still lower. The fats of beef, veal, lamb, milk, and coconut oil contain very little linoleic acid. Margarines and the usual man-made shortenings differ widely in linoleic acid content, depending on the raw materials used and the extent to which they are hydrogenated.

2) Why is there concern about the kinds and amounts of fat in our diets?

There has been some indication that fat is one of the dietary factors involved in the increase in the number of cases of atherosclerosis and some kinds of heart disease in our population. This is based on such items as the fact that atherosclerosis and heart disease occur more frequently in countries where the food supply is abundant than where the food supply is limited. An abundant food supply usually includes a generous amount of fat. As a country we have the highest death rate from heart disease, but also we have more people in the older age groups. There is the probability that arteriosclerotic heart disease is written on the death certificates of many elderly persons, not because it has been clearly diagnosed, but because there is no discernible active disease, such as tuberculosis, pneumonia, etc. For this reason reported increases in the number of deaths from heart disease could be suspect.

Recently the Nutrition Committee of the Council on Community Service and Education of the American Heart Association studied all of the available data and reported to the American Heart Association and the American Society for the Study of Arteriosclerosis. The Council on Food and Nutrition of the American Medical Association authorized this report for publication in its Journal. Certainly no report could have better origin or ancestry. After reviewing the evidence on the subject of fat as related to heart disease, the conclusion was reached that in the studies made so far, the role of fat cannot be separated from other factors, such as total caloric intake, other nutrients, relative rate of caloric expenditure, exercise, and obesity.

One of the authorities in this field, Dr. Wendell Griffith, writes also in the Journal of the American Medical Association somewhat more cautiously--"Until a clear-cut solution of the problem of the prevention of arteriosclerosis and of its sequelae is forthcoming, it seems wise to assume that a faulty diet may be one of the causative agents. Whether or not dietary fat is, in some fashion, the culprit remains to be proved."

Because cholesterol has been the substance most talked and written about in connection with fat and atherosclerosis, we need to consider a few facts about it. Cholesterol is a fatty material which is synthesized in the body and is a normal constituent of the blood. It is used in making physiological substances which are important in the functioning of the body. A high concentration of cholesterol in the blood may result from faulty metabolism and this has been blamed for causing atherosclerosis and leading to heart attacks. The scientific evidence for this, however, is far from conclusive.

The amount of cholesterol in the food we eat does not necessarily determine the amount of cholesterol in the blood. The body can make cholesterol whether or not there is cholesterol in the food. Low cholesterol diets have received considerable attention in the treatment of certain conditions but the extent of their usefulness has not yet been clearly established. A low cholesterol diet limits the selection of highly nutritious foods and could lead to an imbalance or deficiency of nutrients.

19

The amount of cholesterol in the blood of normal persons varies within wide limits. Not all persons with more than average amounts of cholesterol in their blood have atherosclerosis, and not all persons with atherosclerosis have more than average amounts of cholesterol in their blood.

There is some evidence that fats with a high content of linoleic acid may help to lower blood cholesterol levels. However, we lack evidence that lowering blood cholesterol reduces the occurrence of atherosclerosis.

Cholesterol is present in varying amounts in foods of animal origin. It is relatively high in such foods as egg yolk, butter, variety meats (liver, kidney, sweetbreads), fat fish, oysters; fairly high in meat and cheese; and is lower in such foods as lean fish, egg white, skim milk. Substances closely related to cholesterol are present in foods of plant origin such as grains, fruits, and vegetables.

To most of the questions which seek specific information in the intricacies of fat requirement and metabolism, the effect of different processing procedures on the nutritive value of fats, and the relation of fat to heart disease we must say, "We do not know." We must not add to the present confusion by trying to give answers to everything, before the right answers are known. Certainly before too many more Outlook Conferences basic research will have provided facts upon which to base right answers and sound recommendations.

3) Finally, what recommendations can the nutritionist make at this time?

We have an obligation not only to keep people as well informed as the facts permit, but also to keep their confidence in our efforts to serve them even though we do not have some answers to the question. Only in this way can we help people to refrain from soliciting or embracing information from unreliable sources.

Now to answer the question "How can we use the scientifically accurate information that is available to date to maintain and improve our health?" In general, we can say that at this time the evidence does not justify a radical change in the kind or amount of fat in the American diet in the hope that by such means the incidence of coronary or cerebral artery disease will be lowered. However, persons with a family history of early deaths from cardiovascular disease may have special diets suggested by their physicians. We should remember that atherosclerosis and coronary heart disease are clinical problems. Diets prescribed for the treatment of disease should not be confused with diets a healthy person can and should eat.

More specifically, nutritionists recommend that people should eat a "balanced diet" using a variety of foods--neither omitting any one kind nor over-emphasizing any one kind. "On the basis of the survey results

discussed earlier, milk, fruit and vegetables are more in need of emphasis than other food groups. Some emphasis but less than on milk, fruit, and vegetables will be placed on meat, grain products, eggs, dry beans and peas.

We urge people to avoid overeating for their level of physical activity and thus avoid excess calories and overweight. This means choosing liberally from the foods which supply many nutrients in relation to their caloric content, and limiting the intake of foods which provide little except calories. Weight needs to be kept within desirable limits for health at every age. Fortunately, the foods which are needed to improve the nutritional quality of present-day diets are low in calories in relation to the other nutrients they supply.

Surely you will agree that our present knowledge offers plenty of challenge for action. Research is continually adding to our knowledge of nutritional needs and the nutritive values in foods. Much research is in progress on the effect of variety, culture, handling and transportation practices, methods of storage and preparation on the nutritive value, quality, and flavor of food. Special attention in research is also being given to the interrelationships of the body's requirements for different nutrients and the quantitative relationship of nutrients in different foods. The practical results of such research will gradually be applied to improve the Nation's food and the Nation's health. But as in the past, it will require the concerted efforts of research, education, and those responsible for producing our food supply and delivering it to the kitchen doorstep.
