UNITED STATES DEPARTMENT OF AGRICULTURE  
Agricultural Research Service

COST OF RAISING A CHILD 1/

Talk by Jean L. Pennock  
Consumer and Food Economics Research Division  
at the 47th Annual Agricultural Outlook Conference  
Washington, D.C., 3:45 P.M., Wednesday, February 18, 1970

What does it cost to raise a child? The answer to this question is another question--how much can you afford to spend?--for costs vary with standards of what is necessary and desirable. These standards are closely related to economic position. Today I shall be talking about costs for children with no more than 4 siblings in families whose level of living is such that their food expenditures are at the level of the Department's low-cost food plan.2/ Very shortly we will also have available estimates at the levels of the moderate-cost and economy food plans.

Using the food plans is one way of setting the economic level in which our hypothetical child lives. For those of you who may not be familiar with the Department's food plans,3/ let me take a moment to describe them and explain their use in this research. They are at four cost levels--economy (the lowest), low-cost, moderate-cost, and liberal. Each provides a guide for estimating the quantities of foods needed for individuals of specified age and sex. Costs for individuals are estimated periodically. These costs can be combined to estimate costs for families of varying size and composition. On the assumption that groups of families that are eating at the same level are living at the same level, the budgets can be used to bridge differences in family size and composition to locate families at comparable levels of living.

---

1/ This paper follows up work reported at the November 1966 Outlook meeting by Lucile F. Mork. As in the earlier work, the methodology was developed by the author, with Carol M. Jaeger, Minnie Belle McIntosh, both formerly with the Consumer and Food Economics Research Division. Dr. J. Patrick Madden, Associate Professor Agricultural Economics, Pennsylvania State University, suggested the regression equation used.

2/ As this paper was being prepared it was discovered that a programming error invalidated estimates for the farm child in the West. Corrections could not be made in time for inclusion in this paper and consequently estimates for this child have had to be omitted.

3/ The plans are described in detail in HERR 20, Family Food Plans and Food Costs, and in CA 62-19, Family Food Plans Revised, 1964, both USDA publications. Prices are published quarterly in Family Economics Review. Modifications made in the pricing of the plans for this research are described on p. 6.

## Estimates in constant vs. current prices

The data we used to derive the estimates of costs of raising a child came from the 1960-61 Survey of Consumer Expenditures conducted jointly by USDA and the Bureau of Labor Statistics. As a result our first estimates are in terms of 1960-61 prices (table 1). Such estimates have little more than historical interest in 1970, in view of a price rise of 23 percent from 1961 to 1969. Consequently we have updated the costs to 1969 prices (table 2). We have also computed costs for a child born in 1951 and reaching age 17 in 1968 so as to reflect the price changes that occurred during his childhood (table 3). The index numbers used in computing prices in tables 2 and 3 are given in table 4 so that costs for a child of any age can be computed in prices of any year between 1951 and 1969.

Whether you will want to use the estimates presented in constant dollars--that is, costs for all ages in prices of a specified year--or in current dollars--prices varying with the year--will depend on the use you plan to make of them. The data in constant dollars are pertinent when allowances for present costs are being considered. Persons in welfare programs determining allowances for the support of dependent children will want data for each age as nearly in today's prices as possible. So will lawyers and courts when support for children is being adjudicated. So will researchers when they are considering the present costs of supporting the youth of the country or of a segment of the population. But the lawyer and court considering the past costs met in raising an individual child will want the costs in current dollars to reflect prices throughout the child's lifetime. So will the researcher interested in past costs of a cohort of individuals.

First, let us consider costs in 1969 dollars. At the low-cost level we are dealing with in this paper estimates for the first 18 years of life range in constant dollars from \$19,360 for a rural nonfarm child in the North Central region to \$25,000 for a rural nonfarm child in the West. These costs compare to costs ranging from \$15,800 to \$20,190 for a child born in 1951, computed at the prices current in each year through his childhood. Here also the extremes are a North Central rural nonfarm child and a rural nonfarm child in the West.

## Proportion of family income required per child

There are many differences between costs relating to where the child lives, but some generalizations are possible and of interest. Over the 18-year span we are considering, costs per child in constant dollars at the time of the survey--1960-61--consumed from 15 to 17 percent of family income (table 5). The percentage is lowest for the farm child in the Northeast and North Central regions. There income has to be spread to cover somewhat more children than elsewhere.

## Variation by age of child

Even without taking into account the effects of price change over the life

span of the child, total costs per year generally rise as the child grows. In 1969 dollars, costs in the eighteenth year are about 30 to 45 percent higher than in the first year.

Price changes over the life of a child may increase the variation in annual costs. Consider, for example, the child born in 1951. In that year and the next, you may remember, the Korean crisis caused a sharp rise in prices. Subsequently food and clothing prices dropped somewhat, but by 1957 average prices for the goods and services we have grouped together in our tabular presentation were all back to the 1951 levels or higher. Since then the trend has been generally upwards, and the rate of increase has been accelerating in recent years. As a result, the costs in the child's eighteenth year, in 1968 dollars, are about 75 to 95 percent higher than the costs in his first year, in 1951 dollars. This is more than double the difference in constant dollars.

Costs do not all rise at the same rate over the life span of the child. The increase is sharpest in clothing and food, categories for which we have the best basis for estimating individual costs--in food from the food plans and in clothing from the reports for individuals in the survey.

In other categories of consumption, the survey is limited to data on expenditures for the family as a whole. Data from another survey have been used to determine the proportion of family expenditures for medical care to be assigned to the child.<sup>4/</sup> Lacking information on the shares of housing, transportation, and miscellaneous goods and services used by each family member, we have given the child his per capita share of these categories, making no distinction on age although there is some inequity in this procedure. The infant and the teenager do not require equal amounts of transportation, for example, yet we assign them equal shares of the family costs.

When costs are assigned on a per capita basis and family expenditures do not vary in proportion to family size, costs per child can be expected to decrease through the years when family size tends to increase and to turn upward again when the child is a teenager and has fewer brothers and sisters at home. This pattern is evident in transportation but is most marked in housing.

Food and clothing costs also increased more than other costs between the child's first and eighteenth year when costs are expressed in constant dollars. Price changes between 1951 and 1968 in food and clothing were less than in other categories but not enough less to counterbalance the relative changes in real or constant-dollar costs.

#### Relative importance of the categories

A pattern in the way total costs are distributed among the categories of consumption is easily discernible in the estimates by region and urbanization.

---

<sup>4/</sup> For more detail on the computation of costs for medical care and other categories of consumption, see pp. 9-10.

Housing generally takes a larger share than any other category over the child's first 18 years--up to 30 percent of the total. Food is a close second to housing and exceeds it among Northeast farm and urban children. Clothing and the residual category that includes recreation and personal care each take roughly the same proportions--usually 10 to 12 percent. Transportation takes somewhat more. The smallest proportions are used on medical care--4 to 6 percent--and education--about 1 percent.<sup>5/</sup>

### Rural-urban differences

The opinion is rather widely held that rural people can live more cheaply than city people. It has been suggested, however, that when we expect farm people to live at less cost we frequently also expect them to live less well. In this study we have attempted to hold levels of living constant, measuring costs as the value of goods and services used without regard to whether they were purchased or home-produced.<sup>6/</sup>

We find that when levels of living are held constant, there is little difference in costs for the farm, rural nonfarm, and urban child in the South. Costs for the urban child are appreciably higher than for the two rural children in the North Central region, but in the Northeast and West the rural nonfarm child has the highest cost. Food and housing costs of the urban child are generally higher than these costs for a rural child in the same region. His transportation costs are generally lower.

I would like to be able to tell you what part of these differences between requirements for farm, rural nonfarm, and urban children result from the choices families make because of differences in needs and preferences and how much from variation in price levels. However, we worked from expenditure data in which it is not always possible to determine the quantities consumed and never possible to determine whether items bought by farm and nonfarm households were of like quality.

I mentioned a moment ago that we have attempted to hold level of living constant. Because it is harder to do this between farm, rural nonfarm, and urban situations than between regions of the country, perhaps this is the point at which I should tell you something about our procedures and assess our success.

As I said earlier, we are proceeding on the assumption that families who are eating at the same level of adequacy are living at the same level of adequacy in other respects. In other words, we are assuming that family spending is "of a piece" across the areas of consumption--that families will apply the same standards in all areas of spending.

---

<sup>5/</sup> Any college expense that may have been incurred before age 18 is not included. For a more detailed explanation of the derivation of the estimates for education, see p. 10.

<sup>6/</sup> Goods and services received as gift or pay, except food and housing received as pay, are not included in the analysis. For treatment of home-produced food, see p. 8.

We must recognize, however, that the goods and services families buy are only one factor in determining levels of living. Goods and, more frequently, services furnished by the community also are a part of level of living but are not included in our basic data. A few differences in the level of community services may be reflected in the level of family spending, many will not be. If school systems do not provide free school books, families must. This may be one explanation for higher education expenses among southern farm families. If free libraries are not available, families may buy more books and keep up their level of living. On the other hand, they may read less and be at a lower level of living. If government does not provide police protection, few families will be in a position to buy it privately and their level of living will be reduced. But as long as we are concerned primarily with the out-of-pocket costs of families, inequalities in community services are of little moment.

Of more importance than inequalities in community services to our thesis that families eating at the same level are living at the same level is the implicit assumption that all goods and services are equally available to all families, without cost differentials, and that differences in selections made are based only on differences in needs and preferences. This is not universally true. While price differences are believed to be decreasing, some still exist. Location also accounts for some differences in costs that are not true price differences. A farm family, for example, may have to pay mileage costs in addition to the standard fee for a physician's house call. And a farm family will usually have to pay for room and board when a child attends college, whereas many city children can live at home while attending college. On the other hand, the city child may have to spend money to reach and enjoy the fresh air and open space that constantly surrounds the farm child at no cost. The pressures of population also result in the urban family paying more than the rural family for comparable housing. In any of these instances the family facing higher costs may decide to buy less of the commodity and more food. On the other hand, the family facing lower costs may put some or all of the money saved into more food. In both cases, the relation between food and other consumption is distorted and our thesis that families eating at the same level are living at the same level is not universally true. However, it is probable that these distortions average out to some extent when families are grouped together.

### Regional differences

There are considerable differences among the regions in the absolute level of the estimated cost of raising a child and no consistent pattern in these differences. Regional differences are greatest for the rural nonfarm child. For this child, the highest estimate, for the West, exceeds the lowest estimate, for the North Central region, by almost 30 percent. The distribution of costs among the categories of consumption, on the other hand, shows few regional differences. Most noteworthy is that food tends to take a high and transportation a low proportion of total costs in the Northeast.

### Methodological statement

As some of you will remember, we presented estimates of the cost of raising a farm child in the North Central region and the South on this program in

November 1966. My presentation today would not be complete without discussing briefly the changes we have made in our methodology and the differences they have caused in the two sets of estimates.

First, let me review our use of the food plans--specifically the low-cost plans. The low-cost plan, as published in CA 62-19, Family Food Plans Revised, 1964, and priced for the four regions annually in Family Economics Review, suggests amounts of 11 groups of food that together provide an adequate diet. The difference in the cost of food in the four regions comes about partly because in pricing the plans choices of foods in each food group are based on the food habits of the lowest third of families in each region. In the South this is a lower income level than in the other regions. If we are to use the cost of the food plans to locate families at a constant level of living we cannot permit differences in income to affect food choices and determine, even in part, the cost of the plans. We have therefore used one set of food choices--the U.S. nonfarm average--and priced them in the same income class throughout. By this procedure we have eliminated as far as possible differences attributable to differences in income level. The remaining cost differences between regions and urbanizations are largely attributable to variations in price levels. These price differences, of course, must be taken into account in locating families at the same level of consumption.

Pricing the U.S. average nonfarm choices in all regions and urbanizations brings the costs of the food plans closer together both across regional lines and as between farm, rural nonfarm, and urban areas. And of particular importance in explaining differences in our 1966 and present estimates of the cost of raising a farm child in the North Central and Southern regions, this procedure reverses the relation of the food plan costs for North Central and Southern farm families at the low-cost level. Whereas in the 1966 computations, costs in the South were lower, they are now higher than in the North Central region. These changes can be illustrated in costs per week for the low-cost food plan for the usual budget family of four, a husband and wife aged 20 to 34 and 2 children aged 7 to 9 and 10 to 12. The pricings used in 1966 and in our present computations, both in 1960-61 dollars, are:

	<u>Used in 1966 computations</u>		<u>Used in 1970 computations</u>		
	<u>Rural farm</u>	<u>Rural nonfarm and urban</u>	<u>Rural farm</u>	<u>Rural nonfarm</u>	<u>Urban</u>
North Central	\$21.30	\$25.40	\$22.30	\$22.80	\$25.10
South	18.50	21.00	22.70	22.90	22.90
Northeast	23.90	26.80	25.60	25.50	26.00
West	23.10	27.20	24.30	25.70	26.30

Principally as a result of the reversal of the relative positions of costs of the North Central and Southern low-cost food plans, the relative positions of our estimates of the costs of raising a farm child have also been reversed in the two regions. In 1960-61 dollars the old and new low-cost estimates are:

	<u>1966</u>	<u>1970</u>
North Central	\$15,010	\$16,010
South	13,270	17,830

Both the earlier and present estimates are based on regression analysis. In the earlier analysis, the estimate for each category in each region and urbanization was compiled from a series of nine regressions, each using data for that region and urbanization only and for one family type and usually one or two family sizes. This procedure requires a very large sample and we would probably not have been able to develop estimates for the farm population in the Northeast, and the rural nonfarm population in the Northeast and West if we had stayed with it.

The present estimates are based on multiple regressions which utilize the data for all children in families of husband and wife, one to five children, and no other persons. It permits the introduction of tenure and age of the head of the family, pertinent variables not used in the earlier procedure.<sup>7/</sup>

The new equation forms, together with the changes in the level of the food plan costs have resulted in some changes in the make-up of our total cost figures. Because the level of total costs was raised somewhat in the North Central estimates and more so in the Southern, the proportion of the total taken by food has decreased in both regional estimates but more in the Southern. In the latter, there is also an appreciable decrease in the proportion going to transportation. In the South, these shifts are balanced principally by an increase in the proportion going to housing. In the North Central, the decrease in the proportion for food is balanced principally by an increase in the proportion for the miscellaneous category that includes personal care and recreation.

## Methodological Appendix

### Regressions used

Allowances for all the categories of consumption except food at home were obtained by a two-step procedure. As a first step, a proxy for the normal level of consumption was determined at the level of the low-cost food plan. As a second step, each of the categories was determined at the level of the proxy for normal level of consumption.

The regressions used were:

$$F = f(P, P^2, \underline{RU}, H, S, T, A)$$

$$X = f(P, P^2, \underline{RU}, H, S, T, A)$$

The terms are defined as follows:

F = food consumption defined as the sum of expenditures for food at home or to be carried from home, one-half of expenditures for food away from home except expenditures for school lunches, the value of meals received as pay,

---

<sup>7/</sup> The regression equations used are discussed further below.

and 40 percent of the value of home-produced food. The adjustment to expenditures for food away from home was made to transform expenditures to a food-at-home basis for use in conjunction with the food plans in which it is assumed that all meals are from the home food supply. In the 1955 Household Food Consumption Survey the cost of a meal away from home was approximately twice the cost of a meal at home. Expenditures for school lunches were not similarly deflated because family expenditures meet only a part of the total cost. The value of home-produced food was reduced because analysis of data from the 1960-61 Survey of Consumer Expenditures indicates that 40 percent of home-produced food substitutes for purchases and 60 percent increases the level of food consumption.<sup>8/</sup> This adjustment is necessary because of the basic premise that families at comparable levels of living have comparable food consumption.

P = the sum of family expenditures for food (actual, not adjusted), clothing, housing, education, transportation other than automobile purchase, personal care, reading, recreation, tobacco, alcoholic beverages, miscellaneous family expenditures, gifts and contributions, and personal insurance. These are the categories of family outlay relatively unaffected by year-to-year variations in family income. Their sum is used as a proxy for the permanent or normal level of living in determining the average level of expenditure for the individual categories.

RU = region and urbanization.

H = tenure of the family home.

S = family size in year-equivalent persons.

T = family type. The data are limited to three family types. All are comprised of husband and wife, unmarried children, and no other persons. The distinction between types is based on the age of the oldest child--under 6 years, 6 through 17 years, and 18 years and over.

A = age of the head of the family.

X = , in individual equations, family expenditures for food away from home, clothing for children (by age of child), clothing materials and services, housing, medical care, education, transportation other than automobile purchase, automobile purchase, and all other.

In determining the value for P in specified classes F is set at the estimated cost of the food plan for the class. In determining the value for X, P is set at the value derived in the first equation. Estimates were developed for all family type-size classes in each region and urbanization on the basis of the known average age of the head and known age of the oldest child and assumptions as to the age distribution of other children.

---

## Content of the categories

In one category of consumption, clothing, the survey data indicate the individual for whom the expenditures were made. We can, therefore, develop cost estimates tailored to specific age groups. In the other categories of consumption, however, expenditures were reported on a family basis. In these categories, except as noted in the discussion of food away from home and medical care, the child has been assigned his per capita share of the family's expense. These per capita cost estimates were developed independently for children in families with oldest child under 6 years of age, 6-17, and 18 and over, using the family size-type groups indicated above.

Estimates in tables 2 and 3 have been rounded to the nearest \$10 to avoid a false appearance of precision. Table 1, which is essentially a worktable, carries the data to the nearest \$1.

The estimated costs in the various categories of consumption were computed as follows:

Food.--The cost for food at home is the cost of the food plan for a child of the specified age to which adjustments have been made (1) for the economy of scale involved in family size, and (2) to compensate for the costs for meals and snacks away from home. The age intervals used are those of the food plans as published in 1961:

Under 1	4-6	13-15
1-3	7-9	16-17
	10-12	

No differentiation in costs has been made for sex. The costs in the age intervals in which the food plans differentiate between costs for boys and girls are averages of the food plan allowances for boys and girls.

The estimated cost for food away from home is the child's per capita share of expenditures for meals other than those at work, at school, and for snacks. It is assumed that no children in the age range we are concerned with were employed and so we allowed no meals at work. We also assumed that children under 4 years of age do not eat in restaurants. Because a meal bought away from home costs roughly twice as much as a meal at home, one-half the cost of meals away from home has been subtracted from the cost for food at home.

Clothing.--The estimated costs are derived from the actual expenditures for children in the following age groups:

Under 2	6-11	16-17
2-5	12-15	

To these has been added a per capita share of family expenditures for clothing materials and services.

Housing.--This category includes the cost for the family dwelling; fuel, light, refrigeration, and water; household operations; and housefurnishings and

equipment. The cost per child is a per capita share of the family's reported expenditures.

Medical care.--The family expenditures reported in the 1960-61 Survey of Consumer Expenditures were assigned among individuals on the basis of the variation in individuals' expenditures by age in a survey conducted as part of the National Health Survey.<sup>9/</sup> When the expenditures of persons 15 to 44 years of age are set at 100, the relatives are as follows for the income levels shown:

<u>Age</u>	<u>\$2,000-\$3,999</u>	<u>\$4,000-\$6,999</u>	<u>\$7,000 and over</u>
Under 15 years	39.8	45.5	51.3
15-44 years	100.0	100.0	100.0
45-64 years	156.5	143.2	141.7
65 years and older	197.2	159.1	197.4

The \$2,000-\$3,999 ratios were used. We have applied the ratios for under 15 years to 15-, 16-, and 17-year-olds rather than the ratio for 15 through 44. Other studies indicate that adolescence is one of the healthiest periods. Therefore the ratio for those under 15 seems more pertinent to this 3-year span than the ratio for 15 through 44 years, which includes the child-bearing years for women and the period in which the degenerative diseases begin to develop.

Expenditures for medical care vary greatly because of the irregular incidence of illness and accidents. In relatively small samples such as these estimates are derived from, the standard error of the average expenditure may be quite large. It is probable that any differences in the source data, resulting in different cost estimates, are not statistically significant.

Education.--Costs were estimated from the expenditures of families whose oldest child was 6 to 17 years of age. Inspection of a selection of questionnaires from the Survey of Consumer Expenditures showed that most of the education expenditures reported by families whose youngest child was under 6 were incurred for the husband or wife, while most expenditures in families whose oldest child was 18 years of age or more were for college education of these older children.

Transportation.---This category includes costs for the purchase and operation of automobiles and for public transportation. The child is assigned a per capita share of expenditures.

All other.--Included here are the child's per capita share of the family's expenditures for personal care, recreation, reading, and other miscellaneous expenditures. Children in the age groups with which we are concerned were assumed not to use tobacco and alcoholic beverages. They have been assigned no cost for insurance or gifts and contributions.

## Adjusting costs for price change

Table 4 presents the percentage changes in prices between the base period and each year between 1951 and 1969 as measured by the Consumer Price Index (CPI). The base period for the urban data is 1960-61; for the farm and rural nonfarm data, 1961. Therefore, two sets of index numbers are shown.

Table 2, showing estimates of costs in 1969 prices, was produced by applying these index numbers to the 1960-61 values in table 1 and summing the results to obtain the total cost in each year of age. Table 3, showing estimates of costs for a child born in 1951 in the prices current in each year of age was produced by applying the index numbers for the calendar year corresponding to the child's age to the values for that age in table 1, and, as in table 2, summing the results to obtain total annual costs.

Index numbers comparable to those in table 4 can be produced for other years. It must be recognized, however, that the effects of rising real incomes, the new goods and services coming on the market, and changing consumer preferences on the mix of food and other goods and services being consumed cannot be built into our updating. Therefore as the span between the base period, 1960-61, and the year for which adjustment is made lengthens either forward or backward in time, adjustment for price change alone becomes increasingly insufficient as a correction to true current costs.

The component indexes of the CPI that have been used to adjust for price changes in the various categories are:

<u>Category</u>	<u>Index</u>
Food at home	Food at home
Food away from home	Food away from home <u>10/</u>
Clothing	Apparel and upkeep
Housing	Housing
Medical care	Medical care
Education	Reading and recreation
Transportation	Transportation
All other	Personal care, reading and recreation averaged

---

10/ The index for food away from home was begun in 1953. Index numbers for 1952 and 1951 were computed using the average percentage annual change in the years 1953-56.

Table 1A.--Estimated cost of raising a farm child at level of low-cost food plan, by region, in 1961 prices  
[In family of husband and wife and no more than five children]

Age of child (years)	Estimated cost for--										Average age family size (Persons)
