## **The CGPRT Centre**

The Regional Co-ordination Centre for Research and Development of Coarse Grains, Pulses, Roots and Tuber Crops in the Humid Tropics of Asia and the Pacific (CGPRT Centre) was established in 1981 as a subsidiary body of UN/ESCAP.

### **Objectives**

In co-operation with ESCAP member countries, the Centre will initiate and promote research, training and dissemination of information on socio-economic and related aspects of CGPRT crops in Asia and the Pacific. In its activities, the Centre aims to serve the needs of institutions concerned with planning, research, extension and development in relation to CGPRT crop production, marketing and use.

### **Programmes**

In pursuit of its objectives, the Centre has two interlinked programmes to be carried out in the spirit of technical cooperation among developing countries:

1. Research and development which entails the preparation and implementation of projects and studies covering production, utilization and trade of CGPRT crops in the countries of Asia and the South Pacific.
2. Human resource development and collection, processing and dissemination of relevant information for use by researchers, policy makers and extension workers.

### **CGPRT Centre Working Papers currently available:**

Working Paper No. 40 *Effects of Trade Liberalization on Agriculture in Vietnam: Institutional and Structural Aspects*  
by Nguyen Trung Que

Working Paper No. 41 *Effects of Trade Liberalization on Agriculture in Indonesia: Institutional and Structural Aspects*  
by Erwidodo

Working Paper No. 42 *Effects of Trade Liberalization on Agriculture in China: Institutional and Structural Aspects*  
by Jikun Huang and Chunlai Chen

Working Paper No. 43 *Effects of Trade Liberalization on Agriculture in China: Commodity Aspects*  
by Jikun Huang and Chunlai Chen

Working Paper No. 44 *Effects of Trade Liberalization on Agriculture in Pakistan: Commodity Aspects*  
by Muhammad Ramzan Akhtar

Working Paper No. 45 *Effects of Trade Liberalization on Agriculture in India: Commodity Aspects*  
by Ramesh Chand

Working Paper No. 46 *Effects of Trade Liberalization on Agriculture in Malaysia: Commodity Aspects*  
by Tengku Mohd Ariff Tengku Ahmad and Ariffin Tawang

# Foreword

Agriculture plays an important role in the growth and stability of the economy of Bangladesh. The great uniformity of the landmass, the fertile alluvial soil and the tropical monsoon climate provide excellent conditions for agricultural production. Although the share of agriculture in the gross domestic product is likely to decline, agriculture will remain the single largest contributor to the economy in the years to come. The food crop sub-sector dominates the agricultural scenario in Bangladesh, accounting for about three-quarter of the total agricultural output. Rice is the major cereal and largely determines the rate of progress in this sector.

An Agricultural Statistical Profile of Bangladesh, 1947-1999 is the seventh in the series of the CGPRT Centre's publications providing specific and wide-ranging agricultural data focusing on coarse grains, pulses, roots and tuber (CGPRT) crops in Asia. This volume covers 17 CGPRT crops and two major cereals showing area, production and yield.

The agro-statistical indicators are divided into a number of groups as follows:

- (1) General indicators: population, GDP and meteorological data;
- (2) Agricultural census: structure of agricultural holdings, households by size and type of farm;
- (3) Crop statistics: major cereals: rice and wheat; coarse grains: maize, barley and jowar; pulses: gram, arhar, masur, motor, mungbean, mashkhalai, khesheri and til; oilseeds: rape, mustard, groundnut and linseed; roots and tubers: sweet potato and potato;
- (4) Commodity prices: monthly wholesale price by commodity;
- (5) Food balance: foodgrain production and requirement gap; foodgrain budget and stock position;
- (6) Foodgrain import: foodgrain import by source and type; annual and monthly;
- (7) Foodgrain distribution: public distribution by channel; monthly off-take and shares;
- (8) Agricultural inputs: distribution of improved seeds, chemical fertilizer, pesticides and irrigation by method (low lift pump, deep tube-well etc.); and
- (9) Agricultural land use: land utilization, cropping patterns, cropping intensity, area irrigated by crop and method.

A brief introductory text and a rough interpretation are presented here along with general comments on the prospects of agriculture of Bangladesh.

The datasets stored in this volume were collected and compiled by Dr. Mohammad A.T. Chowdhury, Database Specialist, and Mr. Harry Zulfikar, Database Staff, of the Centre. I thank them for their devoted work in this regard.

My special gratitude should go to H.E. Dr. M. Afsarul Qader, Ambassador of Bangladesh to Indonesia, for his kind assistance in obtaining government statistics of Bangladesh.

It is hoped that these datasets will be useful to policy makers, researchers, students and those involved in formulation and implementation of research/development projects not only in Bangladesh but also in other countries.

February 2001

Haruo Inagaki  
Director  
CGPRT Centre

## Acknowledgements

We would like to express our sincere thanks to Dr. Haruo Inagaki, Director of the CGPRT Centre for his support, encouragement and guidance in the preparation and publication of this working paper. Thanks are also due to H.E. Dr. M. Afsarul Qader, Ambassador of Bangladesh to Indonesia, for his kind cooperation with the CGPRT Centre.

The statistical information contained in this publication was largely collected from the Bangladesh Bureau of Statistics (BBS) through the Bangladesh Agricultural Research Council (BARC), the Centre's partner organization. Mr. Assad Alam Siam, a diplomat of the Embassy of Bangladesh in Jakarta, kindly made available to us the "Handbook of Agricultural Statistics 1999" published by the Sector Monitoring Unit, Ministry of Agriculture, Government of the People's Republic of Bangladesh. We would like to acknowledge the cooperation of Mr. Siam and these agencies that have provided to us the valuable data.

In particular, we would also like to acknowledge Dr. Douglas R. Stoltz for his editing services, Mr. Mohammad Arif for his GIS support, particularly in creating the digital map file (boundry) of Bangladesh, Ms. Fransiska A. Wijaya for the graphic layout and Ms. Agustina Mardyanti for her typing services.

Mohammad A.T. Chowdhury  
Harry Zulfikar

# **1. Bangladesh: an Overview**

## **1.1 Historical background**

Bangladesh became a sovereign nation on 16 December 1971. The prior unification of East and West Pakistan into one nation was part of the partition of British India in 1947. Eventual polarization of policies and positions between the two regions culminated in difficulty in maintaining solidarity and resulted in separation.

## **1.2 Area, location and the boundary**

Bangladesh is the eighth largest country in the world in terms of population, but occupies a very small land area covering only 143,999 square kilometers or 55,598 square miles. The country is located in the northeastern part of South Asia between 20° 34" and 26° 38" north latitude and 88° 01" and 92° 41" east longitude, bordered by India in the west and north, India and Myanmar in the east and the Bay of Bengal in the south.

## **1.3 Administrative divisions**

The country is organized into four administrative divisions i.e. Chittagong, Dhaka, Khulna and Rajshahi (named for their capital cities, Figure 11). While there is some ecological variation among the four divisions, the differences are not conspicuous and certainly not of the magnitude found in other nations with a more varied geographical structure. Each division is sub-divided into zillas (district), thanas (sub-district/police station) and unions (village council). Presently, there are 69 districts (previously 21) in Bangladesh. Each district consists of several thanas (later named as upazila, total 464). Each thana consists of several unions (total 4,409). Each union is administered by a chairman, elected by the people.

## **1.4 Physiography**

Geographically, Bangladesh occupies a large part of the massive delta formed by the Ganges, the Bhramaputra, and the Meghna river systems through which rainfall from the catchment area and the melted snows of the Himalayas drain into the Bay of Bengal. Being essentially a delta, the nation is a flat, fertile, alluvial plain with a fairly homogeneous type of land resource. Elevation seldom exceeds 10 m above sea level, with major exceptions being the Chittagong Hill Tracts region in the southeast, the low hills of the Sylhet district in the northeast, the Barind Tract in the northern region and the Madhupur Tract in the central region (Figure 21).

A most impressive characteristic of the landscape is the profusion of rivers including the Padma, the Jumuna, the Meghna and the Karnafully and their numerous tributaries that traverse most regions of the country. Tropical monsoon rains drench the land and the rivers overflow their banks and cause flooding of low and outlying areas almost every year. As a result of frequent flooding, the land has been continuously enriched by heavy silt deposition during the rainy season.

## Chapter 1

However, there are other problems associated with these mighty rivers. Many of the lowland areas in the country, that are inundated during the high water season, have a limited production cycle of one crop annually. Further, a significant area of land is eroded by water movement, especially along unprotected riverbanks. The Bangladesh Water Development Board has estimated that about 1,200 km of riverbank are actively eroding and more than 500 km face severe problems related to erosion. Satellite image studies of the Ganges-Brahmaputra-Middle Meghna rivers between 1982 and 1992 show that 106,300 ha were lost to erosion, while only 19,300 ha were accreted. The net area of 87,000 ha lost, most of it agricultural land, is equivalent to an annual erosion rate of 8,700 ha (World Bank 1998).

### 1.5 Land use

The land resource of Bangladesh totals about 14.3 million ha, and the land is cultivated with moderate intensity. About 60% of the total land area is devoted to crop production in a given year. Cereals, mainly rice and wheat, account for two-thirds of agricultural production. Area under cereals accounted for 76% of the total cropped area in 1983/84. The area under pulses, oilseeds and vegetables was reported to be 6.6, 4.4 and 2.2% of the total cropped area, respectively, in the same year (Table 9.2). Forests occupy about 15% of the land area. Only 1.7% of land is considered waste and much of that is potentially reclaimable, but at a relatively high economic cost.

Changes in land utilization have not been significant since the independence of Bangladesh. The major increase in agricultural land use has been associated with rice, wheat and potatoes, while the area under jute cultivation has declined. Marginal increases in area have occurred with rape, mustard and masur or lintel. Land use for other crops has remained more or less stable, except in very limited cases, where irrigation and market access have encouraged small shifts to higher value cash crops. Apparently, some land has moved from “culturable waste” and “current fallow” to crop production over the years. A slight reduction in forest area and a minimal increase in “not available for cultivation” land are the only other changes in land use of any note.

From a regional perspective, there is a gross disparity in the distribution of culturable wasteland in Bangladesh. For instance, in 1988/89 the amounts of cultivable wasteland in Bandarban, Chittagong and Sylhet districts were 48,966, 14,163 and 65,963 ha, respectively. In 1997/98 these numbers, however, increased remarkably to 56,251, 94,290 and 116,548 ha. On the other hand, smaller districts such as Bogra and Tangail reported lower amounts of culturable wasteland (1,619 and 2,023 ha, respectively) and greater stability over time (Table 9.11). It has also been noted that, despite the overall decline in the area of current fallow land since 1988/89, Sylhet, Barisal, Rangpur and Rangamati districts still show a higher proportion of this category of land.

The current land use seems to reflect no major shifts in utilization pattern unless significant changes occur in the underlying technical and economic determinants of returns to the various uses of land. This does not, however, rule out changes within uses, especially in crop land, as farmers continue to make individual adjustments based on their best options.

### 1.6 Soil

Except for a few upland areas, virtually all the soils in Bangladesh are alluvial with little or no profile development. The entire Ganges Delta is geologically active with constant erosion and deposition. There are seventeen soil types in Bangladesh. These soils occur in six agro-ecological zones identified by their flooding characteristics. Many types of alluvial deposit

combine with small (a few centimetres) variations in profile to create fundamentally different moisture regimes that affect plant adaptability (Rahman 1990). The soil reaction characteristics in the agricultural production regions of Bangladesh are shown in Figure 22.

## **1.7 Climate**

Bangladesh enjoys a tropical monsoon climate characterized by three main seasons: (1) a hot and humid summer season from March to early May, (2) a hot and humid monsoon season from June through October, and (3) a cool and drier winter season from November to February. During the summer period, northwesterly airflow predominates, bringing moderate rainfall. This period is followed by the monsoon season with much heavier rainfall. Winter is quite pleasant with a minimum temperature around 10°C. Frost is nonexistent in the country and is not a risk factor in agricultural production.

Bangladesh is located at the edge of a tropical zone. Its temperature ranges from a mean of about 28°C in July to 18°C in February. The summer temperatures range from 32°C to 35°C, with readings of 40°C or higher immediately before the onset of the monsoon. The geographical differences in Bangladesh are not that great, but the higher temperatures tend to occur in the north and west. Temperatures as low as 4°C are experienced in the hill areas, although temperatures in most part of the country rarely fall below 10°C.

The monsoon period accounts for 80% of the total annual rainfall. The average annual rainfall varies from 1500 mm (60 inches) in the west to more than 3000 mm (120 inches) in the east, covering the coastal areas of Chittagong and the northern parts of Sylhet district. This is a very critical risk factor in agricultural production, since there is a high degree of rainfall variability in Bangladesh from year to year. A delay of seven to ten days in the arrival of monsoon rains can have a drastic impact on the total grain harvest. Floods and drought are common consequences of the extreme weather patterns found in Bangladesh, causing not only crop damage but also affecting the livelihood of the rural masses. The 1987 and 1988 floods caused widespread destruction of crops and loss of life. Other catastrophies can arise from the violence, which sometimes occurs with cyclones and other weather extremes. Cyclones have profound influence on the utilization of land in the coastal areas.

## **1.8 Water resources and irrigation**

One of Bangladesh's principal resource endowments is its water that holds the key to agricultural development. The intricate network of alluvial rivers carries a huge annual discharge to the Bay of Bengal amounting to 1.5 million cubic m per second at peak periods, which is double the flow of the Mississippi River. The flatness of the whole region however makes development of hydro-electric power impractical (except the Chittagong Hill Tracts), but irrigation potential is extremely good. Pumping directly from the river provides the most immediate opportunity due to the ease of access to water.

Additionally, the geological structure produces excellent supplies of groundwater throughout the country. Although the supply of groundwater has not yet been accurately determined, estimates indicate that sufficient amounts are available to meet most projected irrigation demands, although deficiencies may arise especially during the dry season. The answer to the question of availability of groundwater lies in the estimate of annual groundwater recharge. According to the Master Planning Organization (MPO) in 1991, the potential groundwater recharge (defined as the annual volume of surface water that could reach the aquifer) in Bangladesh was estimated at 72,000 million cubic m. Useable recharge constitutes 75% of the potential recharge or 54,000 million cubic m. Taking into account geographic and

## Chapter 1

physical constraints, MPO further reduced useable recharge to arrive at an estimate of available recharge at 21,100 million cubic m.

The 1991 estimate of groundwater availability indicated that by 2010 there would be a net surplus of nearly 1.4 billion cubic m after domestic, industrial and agricultural demands were met. The same year, MPO projected that the demand (on the basis of anticipated irrigation projects) for irrigation water in March 2018 would be 14,290 million cubic m. The needs of the agricultural sector account for 58.6% of the total water requirements (24,370 million cubic m) in the country. About 50% (11,740 million cubic m) of the anticipated supply will come from the main rivers and 23% from the ground source. It may be noted here that the supply of water from all sources was expected to be 23,490 million cubic m. Hence, there was a projected shortfall of 880 million cubic m of water (World Bank 1998). However, the assumptions of these projections will most likely change because of factors such as the 1997 water treaty with India.

The irrigation pattern shows that Bangladesh would be wise to depend on groundwater irrigation. Estimates from the National Minor-Irrigation Development Project indicate that in the 1994/95 irrigation year, a total of 2.2 million ha were irrigated by groundwater, and that there is enough to irrigate an incremental 5 million ha. The economic cost of groundwater extraction in the long run may be too high. Normally, shallow tube-wells can reach groundwater in most regions of the country at depths of about 12 m, but water is commonly available at less than 6 m.

In 1995/96 a total of 3.75 million ha of land was irrigated in Bangladesh. Minor irrigation equipment included shallow tube-wells, which covered about 60% of the total area under irrigation, low-lift pumps, which irrigated 17% of the total area and deep tube-wells, which irrigated 16% of the total area (World Bank 1998). It may be pointed out that all agricultural production regions of Bangladesh are suitable for shallow tube-well irrigation with the exception of the coastal belt bordering the Bay of Bengal, the Madhupur area northwest of Dhaka, the Barind area in North Bengal, and the entire Sylhet and Chittagong Hill Tracts region, where deep tube-wells are needed.

A look at the economics of irrigation in Bangladesh indicates that the low-lift pumps are the most cost-effective of all minor irrigation technologies in the country. For farmers, who used low-lift pumps in 1995/96, profits were extremely high with an internal rate of 64%. Shallow tube-well earned a rate of 61%. Deep tube-wells were found to be economically unviable. Their internal rate of return was 21%. According to World Bank estimates (1998) major irrigation schemes, which account for less than 10% of irrigated land in the country, appear to be the least viable of all modes of operation (the economic rate of return for such projects ranges between 11 and 12%). They are heavily subsidized and claim about 50% of development expenditure of the agriculture sector.

### 1.9 Cropping patterns

In general, the rainfall and temperature of Bangladesh provide excellent conditions for agricultural production. The climate and land resource endowment are capable of producing a wide variety of products year-round, although the agricultural sector of Bangladesh is basically a rice economy. The year-round growing season offers considerable potential for multiple crops, provided that cropping patterns and resource availability can be properly coordinated.

Cropping cycles are closely associated with rainfall and climatic patterns (Figure 23). Among the major crops, aman rice (particularly the broadcast aman), and to some extent aus rice have production cycles to take advantage of the monsoon rains. boro rice, on the other hand, has been developed to follow the heavy rains and requires winter irrigation for optimal

production. Wheat, potatoes and most of the pulses, oilseeds, and vegetable crops, which are grown during the winter months, can benefit from irrigation. However, irrigation is not widely applied to these crops.

### **1.10 Agricultural production regions**

The similarities in landscape and climate across most of Bangladesh make agricultural production reasonably homogenous. Still, one can identify four broad agricultural production regions in Bangladesh that coincide with the four administrative divisions (Figure 11). Most crops are produced in every geographic region; yet there are significant microclimatic and geographic variations that can influence production patterns. Rice dominates the production milieu in the agricultural sector. The lesser food crops include wheat, pulses, oilseeds and vegetables including potatoes. Livestock, fish and forestry are other important components of the agricultural sector.

The Chittagong region, with its higher rainfall, especially in its Sylhet and Chittagong Hill Tract Districts, contains the major portion of the forest regions of Bangladesh. This region produces a significant share of most crops. About 25% of the nation's acreage is committed to rice, fruits, spices, vegetables, oilseeds and potatoes. Sweet potatoes are mostly grown in Comilla District. Chittagong is also the major region for Boro rice cultivation.

The Dhaka Division is a wet plain region which produces a wide variety of agricultural products. Among the four divisions, Dhaka has the highest level of jute acreage. Boro rice, potatoes and oilseeds are also widely cultivated. Dhaka has 27% of the total land devoted to all classes of rice. Compared with other regions, Dhaka farmers are least involved in the production of wheat, fruits and vegetables.

The Khulna region in the southwest also tends to be a wet plains region, and is the least agriculturally involved of the nation's regions. Significant production of fruits, vegetables, sugarcane, and tobacco is noticed. Only 21% of the nation's rice area falls under this region, mostly Aman and Aus. Potatoes are scarcely grown, and spices and oilseeds are produced sparsely. Khulna region has a major mangrove forest.

The Rajshahi division is the "dry land" region in the north-west plains (assuming that about 60 inches of annual rainfall can be considered dry). It has the most diversified agricultural base among the four divisions. More than 50% of the nation's wheat acreage is located in Rajshahi, primarily in the Districts of Rangpur and Dinajpur. Acreage under sugarcane, pulses, tobacco, and potatoes exceeds 40% of the national total. The largest portion of rice acreage is also located in the Rajshahi region. Only sweet potatoes and Boro rice are not extensively grown in the region.

### **1.11 Socio-economic conditions**

With a population of 125 million half of whom are poor, over 30% of work force in rural areas unemployed, and a GDP per capita of US\$ 240, Bangladesh is one of the world's least developed countries (Choudhury 2000). The major economic resources of the country are the fertile lands, abundant water resources and ample labour force, but due to the lack of capital, technology and skilled human resources, the population cannot be gainfully utilized. The traditional farm sector encompasses a large segment of the population who are engaged in subsistence production and consumption. Low-level technology characterizes most small land holdings as well as low agricultural productivity.

The socio-economic conditions of Bangladesh have been characterized by high population growth rate; high unemployment rate; large scale absolute poverty; increasing

## *Chapter 1*

landlessness; widening disparities in income, wealth and opportunities; low educational level; high infant mortality; poor health and sanitation; malnutrition; vulnerability to natural disasters; severe inflationary pressure; and overwhelming dependence on foreign capital, and imported food and raw materials (Wennergren et al. 1984; Choudhury 2000).

### **1.12 Food security**

The bulk of the population does not have access to sufficient food due to lack of adequate purchasing power. Around 7.7 million rural households are virtually landless and can not produce the food they need for an active and healthy life. About 48% of the total population is income poor, while around 77% of them suffer from malnutrition because of more crippling poverty (Choudhury 2000). Furthermore, food crops are often affected by various natural calamities such as drought, flood and cyclone. There is, thus, a continued insecurity in the domestic food supply in Bangladesh that remains one of the major concerns for the country.

## **2. The Agricultural Sector**

### **2.1 Introduction**

Agriculture plays an important role in the growth and stability of the economy of Bangladesh, accounting for about one-third of GDP and nearly two-thirds of employment. Although the share of agriculture to GDP is likely declining, agriculture will remain the largest single contributor to the economy in the years to come. The sector will not only continue to play a vital role in achieving self-sufficiency in food production, but will also continue to be an important source of export earnings.

### **2.2 Structure of crop production**

The crop sub-sector, which was 79% of the total agricultural production in 1990/91, dominates the agricultural scenario in Bangladesh. Food crops alone account for about three-quarters of the total agricultural output. Rice is the major crop that covers around 75% of the total cropped area, and accounts for about 70% of the value of total crop output (Hossain 1999). Wheat, potato, pulses and oilseeds are the other principal food crops.

The dominance of rice in the crop sub-sector virtually assures stability in the structure of production. In fact, the entire growth in foodgrain production can be explained by the growth in rice production. While total cereal production increased from 11.1 million metric tons (t) in 1970/71 to 21.9 million t in 1998/99, rice production reported an increase from around 11 million t to nearly 19.9 million t during the period (Table 3.7; Figure 5).

Since rice is the main staple, development in rice production has a significant impact on the sector's performance. Major shifts in the crop diversification will be limited as long as rice is important to the diet of the nation. Options for crop diversification exist, and the arguments favouring a broader crop base are persuasive. But, over the past decade or so, there has been a shift in the composition of agriculture focusing on non-crop sectors. While the share of the crop sub-sector has declined from 79% in 1990/91 to 73.2% in 1995/96, livestock, fisheries and forestry have increased their share from 7.2%, 7.2% and 6.6% to 9.7%, 9.6% and 7.5%, respectively (Choudhury 2000). Hence, the approach during the Fifth Five Year Plan 1997-2002, (FFYP) is to develop an integrated agriculture including crops, livestock, fisheries and forestry through more efficient utilization of available land and water for sustainable agricultural growth.

### **2.3 Review of past performance**

Bangladesh made steady progress in agriculture in the post-Independence period. Between 1970/71 and 1996/97, the cropping intensity increased from 148% to 176% (Table 9.3) and food production almost doubled. The net foodgrain (rice and wheat) production increased from 10 million t in 1970/71 to 16.87 million t in 1989/90 (excluding 10% for seed, feed and wastage). The total cropped area increased from 12.14 million ha in 1970/71 to around 14.16 million ha in 1986/87, mainly due to more multiple cropping. While net cropped area increased slightly from 8.7 million ha to 8.9 million ha, area sown grew from 3.6 million to ha 4.5 million ha during the same period (Table 9.1). As regards performance of modern agricultural inputs, the irrigated area increased to about 3.8 million ha in 1997/98 from the level

## Chapter 1

of 1.5 million ha in 1978/79 (Table 9.5). Among other inputs, use of chemical fertilizer increased from 2 million t in 1990/91 to 3.02 million t in 1995/96 (Hossain 1999).

Food production increased substantially over the years following the introduction of high yielding varieties (HYVs) and application of modern inputs, but the dependence on weather continues to result in fluctuations of production. In 1993/94 and 1994/95, foodgrain production declined as a result of natural disasters, particularly floods and droughts in the northwest region, which had become a surplus grain production region. The average foodgrain production during these two years dropped to 18.71 million t from the average of 19.49 million t during the preceding three years 1990/91-1992/93 (Figure 5).

The decline in rice production in 1993/94 also reflected the farmers' response to the fall in rice price in the preceding year. This is evidenced by more than a 4% decline in fertilizer consumption, more than 2% reduction in area sown and a similar decline in irrigation command area (Hossain 1999). However, this trend started improving from 1995/96 with a foodgrain production of 19.06 million t (Choudhury 2000). The years 1996/97 through 1999/2000 are expected to witness an all time high production figure of over 20 million t, although flooding is a real challenge to achievement of the target.

### 2.4 Paddy/rice

Among the three major paddy varieties, aman paddy (sowing and planting: June to September; harvesting: December to January) is by far the most important in terms of both quantity produced and value of production (Figure 5). The aus paddy (sowing and planting: March to April; harvesting: July to August) is the next most important, but its significance has been declining since 1981/82 because of the popularity of boro paddy (sowing and planting: December to February; harvesting: April to June). With the expansion of irrigation facilities, boro paddy will become more important than aus paddy (Figure 5). It is evident that aus rice production decreased from 2.9 million t in 1970/71 to 1.6 million t in 1998/99, while aman rice production increased gradually from 5.9 million t to 7.7 million t. However, the most significant change recorded is in boro rice production, which increased astonishingly from 2 million t to 10.6 million t over the same period (Table 3.7).

This production trend can partly be explained by the area under different rice categories. While area under total rice (aus, aman and boro varieties) increased from 9.7 million ha in 1970/71 to 10.1 million ha in 1998/99, area under aus decreased gradually from 3.2 million ha to 1.4 million ha. It is mainly the expansion of boro rice area (from 0.8 million ha to 3.5 million ha) that has made a significant contribution towards increased rice production during the observation period (Table 3.6).

Progress in rice output can also be attributed to the increase in average yield (Figure 4). Between 1970/71 and 1998/99, the average rice yield increased from 1.13% to 1.97%. However, all HYV yields are declining, while all local rice yields are on the increase. For instance, yields of aus HYV and boro HYV declined from 3.27% and 3.42% in 1970/71 to 1.65% and 3.09% in 1998/99, respectively. This is also true for aman HYV yield, which declined from 2.75% in 1971/72 to 2.04% in 1997/98 (Table 3.8).

### 2.5 Wheat

Wheat output increased significantly in the last three decades, the most remarkable change among all crops. The 1970/71 production level represents about 110,000 mt, which increased to 1.9 million t in 1998/99 (Table 3.7; Figure 5). Area under wheat has also increased remarkably from 125,000 ha to 882,000 ha (Figure 6) with yield increase reporting 0.87% to

2.16% during the period (Tables 3.6 and 3.8). A major reason for this extraordinary expansion has been the adoption of HYVs. In addition, the expansion has been helped by new management practices of farmers.

## **2.6 Coarse grains**

Maize production has remained stable at around 3,000 t over the past three decades with minor exceptions (Table 3.7; Figure 7). Although area under maize decreased from 3.2 thousand ha in 1970/71 to 2.9 thousand ha in 1998/99, a moderate yield increase from 0.9 t to 1 t per ha has offset the area loss (Tables 3.6 and 3.8; Figure 8).

Barley production reports 21,000 t in 1971/72 but dropped to around 5,000 t in 1998/99 (Table 3.7; Figure 7). This is largely because of area reduction under barley from 37.2 thousand ha in 1970/71 to 8.6 thousand ha in 1998/99 (Table 3.6; Figure 8). Yield of barley increased modestly (from 0.5 to 0.6 t/ha), indicating little influence in productivity gain over the period (Table 3.8).

Production of total pulses remained almost stable between 1970/71 to 1981/82 around 271,000 t, but increased remarkably from 1982/83 leading to 499,000 t in 1998/99 (Table 3.10; Figure 9). This increase is mostly attributed by area expansion, since yield has changed very little (from 0.73 to 0.76 t/ha) over the period (Figure 10; Tables 3.9 and 3.11). Oilseeds too depict a similar picture.

## **2.7 Tuber crops**

Production of white potato increased from 849,000 t in 1970/71 to 2.8 million t in 1998/99 (Table 3.10; Figure 9). This is a combined effect of both area expansion and yield increase, showing 87,000 ha to 245,000 ha in area increase, and 9.8 t/ha to 11.3 t/ha in yield increase over the same period (Tables 3.9 and 3.11; Figure 10).

Production of sweet potato is somewhat different. Total production of sweet potato (849,000 t) was similar to that of white potato in 1970/71, but production declined to 383,000 t in 1998/99 (Table 3.10; Figure 9). This is mainly because of area reduction under sweet potato, which changed from 73,000 ha in 1970/71 to 41,000 ha in 1998/99 (Table 3.9). The influence of yield is minor, since there was only modest decline (from 11.3 t/ha to 9.3 t/ha) over the period (Table 3.11).

## **2.8 Other crops**

Production of jute, the golden fiber of Bangladesh, has been erratic since 1973, primarily because of the fluctuations of world market prices and the ease with which substitution between jute and aus rice can occur. Farmers traditionally alter their production between these crops depending on relative profitability. Production of jute fiber reached a high of 8.66 million bales in 1985/86. The production level declined to 4.92 million bales in 1992/93, and has been hovering around that level since. Sugarcane production has remained more or less around 7.5 million t since 1987/88 (Hossain 1999).

## **2.9 Food deficiency**

Despite significant production gains in the agricultural sector, Bangladesh is still a marginally food deficit country, and it will remain a food deficit country for years to come.

## Chapter 1

Although one of the largest producers of rice in the world, Bangladesh has also been one of the largest importers of rice and recipients of food aid since 1971. Food production has remained inadequate to meet the demand generated by the population growth. Between 1980/81 and 1997/98, domestic availability of major cereals (rice and wheat) increased from 13.2 million t to 18.6 million t, while actual food grain requirement increased from 14.9 million t to 20.9 million t during the period. This indicates an increase in total food gap from 1.7 million t in 1980/81 to 2.3 million t in 1997/98 (Table 5.1).

According to the Asian Productivity Organization report, between 1990/91 and 1997/98, the annual food deficiency in Bangladesh ranged from a low of 1.3 million t (1991/92) to a high of 3.4 million t (1994/95) or an annual average of 2.2 million t. This, however, was viewed primarily as a wheat gap rather than a rice gap (Choudhury 2000). The country seems to be approaching a closure of its rice gap, but its wheat gap has largely been filled by food aid that remains a permanent feature of its food supply. The magnitude of the food gap does widen occasionally as a result of natural calamities of various sizes and intensities. Consequently, the import of food grains also fluctuates in accordance with the frequency of natural disasters.

### 2.10 Food balance

The food balance situation is likely to change during the FFYP period (1997-2002). The projected food balance in the terminal year of the Plan vis-a-vis the base year is shown below:

#### Projected food balance in the Fifth Five Year Plan.

	1996/97 (Base Year)	2001/02 (Terminal Year)
Population (million)	123.80	132.50
Food requirement* (million tons)	20.50	21.94
Production of foodgrains (million tons)	20.39	25.12
Seed and wastage (10%)	2.04	2.51
Net production (million tons)	18.35	22.61
Food balance (million tons)	(-) 2.15	(+) 0.67

Source: Hossain 1999.

\* Total foodgrain requirement has been calculated on the basis of per capita daily requirement of 453.59 grams.

During the final year (2001/2002) of the Plan, the total size of the population is estimated to reach 132.50 million. In order to feed them the country will need 21.94 million t of foodgrains. Production of foodgrains has been estimated at 25.12 million t in 2001/02. Out of this, the target for rice production has been fixed at 23.40 million t compared to the estimated production of 18.82 million t in 1996/97. The targets of wheat and other coarse grain production have been set at 1.6 million t and 0.12 million t, respectively, in the final year of the Plan (Hossain 1999). It was estimated that after deducting for seed and wastage from the gross production, 22.61 million t of foodgrain will still be available for human consumption. Thus, if other things remain unchanged, the country will be able to attain food self-sufficiency with a surplus of 0.67 million t by the end of the Plan.

### 2.11 Production constraints

Bangladesh faces substantial obstacles in its effort to become self-reliant in food production. The main problem in increased food production is limited agricultural land and other scarce resources. The low productivity in agriculture is a result of the existence of a variety of factors - economic, social, technological and institutional - as well as gross dependence of the sector on nature. In the crop sub-sector, the following broad constraints exist:

- Absence of effective policy planning as reflected in adverse changes in land use and environment (e.g. unchecked urban expansion).
- Effects of saline intrusion in coastal areas.
- Limited agricultural diversification.
- Unwise changes in cropping patterns.
- Low growth rate in cropping intensity.
- Slow increase in yield level of various crops due to:
  - poor quality seeds and inappropriate seed rates;
  - poor tillage and land preparation;
  - use of fertilizer in unbalanced doses;
  - loss of organic matter in soil and sulfur/zinc deficiency;
  - delayed seed planting; poor weed and pest control; and
  - lack of certain socio-economic and institutional factors such as unfavorable input-output prices, inadequate credit supply and lack of infrastructure.
- Inadequate research base, low efficiency; lack of proper integration of the national agriculture research systems; weak research-extension-farmer linkages.
- Largely ineffective price policy interventions.
- Limited market services and standards.
- Inadequate access to inputs and markets relating to availability, adequacy and timeliness of input supply, and prices of inputs.
- Inadequate physical infrastructure.
- Absence of adequate institutional credit.
- Inadequate investment in human capital; low status of women.
- Lack of appropriate strategies for flood and drought prone areas.
- Absence of appropriate policy framework to sustain landless and small farmers.
- Problems associated with land ownership.
- Unchecked population growth.
- Limited mobilization of domestic resources.
- Deficient export base.
- Inadequate farm power.
- Lack of completeness in coordinating public services.
- Limited database and policy analysis.

## **2.12 Prospects**

Despite the constraints noted above, the natural resource endowment of Bangladesh provides a very optimistic base for expanding agricultural productivity. On the positive side, the topography of Bangladesh is largely uniform and climatic variation is not drastic. The temperatures are ideal for multiple cropping and year round production is possible in most regions. Rainfall patterns sustain an extensive rice production system during the monsoon, although annual flooding limits production alternatives in low-lying regions. The land base is still capable of supporting much higher crop production, particularly from expansion of multiple cropping and more intensive use of the land. Soil fertility and structure are generally good and reasonably homogenous. The massive supply of surface and groundwater for irrigation is economically available. The abundant supplies of natural gas can offer not only an economical source of power generation but also an inexpensive raw material for the production of urea fertilizer.

On the socio-economic side, an increasing number of Bangladeshi farmers are responding to new production opportunities by adopting more cost-effective technologies such

## *Chapter 1*

as chemical fertilizer, irrigation water and HYVs. Their numbers may not be that great, but the economic responsiveness among some farmers generates optimism that widespread changes can take place. The rapid increase in boro rice and wheat production due to the adoption of HYVs, fertilizer, and irrigation is one of the most visible of farmers' responses to new economic alternatives. Similar farmers' responses are also apparent in mustard and potato production. Moreover, the gradual shift of cropping structure between rice and jute illustrates the awareness of farmers to changing economic conditions.

The trend in farmers' acceptance of modern technologies in response to market forces constitutes a basis for optimism that they can become a model for more widespread adoption. The potential is high and, given the demonstrated response of farmers to economic incentives, the probability of significant production changes from adoption of already proven technologies is one of the sector's more promising strengths. However, the modern technological base will have to be more broadly diffused if it is to result in significant increases in agricultural production. The process can be enhanced by sustained government investment in programs to improve the availability of modern factors of production, institutional capacity building and human resource development including education, training, research and extension. Given the limited land base, agricultural production can only increase in Bangladesh with more efficient land use and greater land productivity, and this makes such investment urgent.

Toward this end, Bangladesh has already developed a promising technology base and national agricultural research system (NARS). The type of technology may vary from new and adapted crop varieties to innovative farm management and cultural practices. If given proper assistance, the NARS can grow into an effective system. Local scientists are making important contributions to new technical knowledge. An excellent physical infrastructure and an understanding of the scientific process are already in place. Definitely, development of a research capability will not have to start from scratch, and this can permit a more rapid advancement of institutional capacity to produce streams of necessary technical innovation.

Although Bangladesh has (at least relative to many other LDCs) a good-sized cadre of agricultural scientists and technicians to support the development of science-based agriculture, greater attention must be given to developing human capital. Scientific skills and environmental awareness are needed to produce new technical knowledge and information that will help farmers overcome constraints to production imposed by weather, disease, pests, soil erosion, nutrient deficiencies, and other environmental, economic and cultural conditions. The agronomic and socio-economic problems confronted in Bangladesh agriculture are dynamic and relatively complex, because of the tropical environment and multiple cropping system. Solutions to these problems require a viable institutional system with competent scientists to sustain a continuing flow of updated information and new technical knowledge. Fortunately, Bangladesh has passed the initial stages in its quest for this capability. The modernization of agriculture will advance much more rapidly because of it, especially if the related institutional deficiencies are given appropriate attention and if the base of human capital is improved further.

Most important, agriculture has been accorded a priority position in the national development strategy since Independence. The support of successive governments has been a significant contributing force to the development of Bangladesh. Fortunately, this support has never diminished over time.

### **2.13 Government policy**

Reforms in the agriculture sector have been quite visible and pronounced in the past decade or so. Various policies that have been implemented in this sector include privatization of input distribution, withdrawal of input and food subsidies, trade liberalization and a broadening

of the scope of private investment in agriculture. In recent years, the coverage of policy reforms has substantially expanded to include minor irrigation equipment, agricultural machinery, seeds and agricultural trade. Sustainability of high yield and environmental protection have remained the major public concerns.

The approach during the FFYP 1997-2002 is to develop an integrated agriculture, including crops, livestock, fisheries and forestry through more efficient utilization of available land and water for sustainable agricultural growth. The specific objectives of the FFYP are:

- To increase rural productivity and incomes of farming families on a sustainable basis;
- To attain self-sufficiency in foodgrain production including the development of secondary crops;
- To encourage development of exportable agro-commodities keeping in mind domestic needs;
- To promote adoption and practices of modern agricultural inputs in special areas such as dryland, wetland and coastal belts; and
- To ensure sustained agricultural growth through more efficient and balanced utilization of land, water, fertilizer and integrated pest management.

## **2.14 Strategies**

In order to achieve the above objectives, strategies/policies will be evolved and adopted to bring about the necessary technical changes. The most favoured strategies have been identified as follows:

### *Technology*

- Conservation and better utilization of genetic resources;
- Improvement of crop seeds; assurance of regular, sustained and sufficient supply of quality seeds, e.g. HYV in general and hybrid varieties in particular;
- Development of ecologically sound technologies such as integrated pest management, organic and bio-fertilizers;
- Development of appropriate technologies for reduction of post-harvest losses and transportation damage;
- Restoration/improvement of soil fertility through better management of soil organic matter;
- Development of rainfed, dryland and wetland farming systems to enhance their productivity.

### *Administrative regulation*

- Development of modern, irrigated and low risk agriculture with greater competitiveness;
- Low cost agricultural inputs; more public investment in areas that require supplement for private initiatives;
- Formulation of integrated and optimum land use policies;
- Balanced production of minor crops keeping in view human nutritional needs;
- Facilitation of access to markets and promotion of efficient marketing systems;

## Chapter 1

### *Infrastructure*

- Improvement in infrastructure such as irrigation/drainage systems, transportation systems, road networks, and storage facilities be undertaken to minimize the agricultural constraints.

### *Institutional arrangement*

- Strengthening of the agricultural research and extension systems focusing on development of new crop varieties, integrated farming systems, organic farming and crop processing;
- Necessary institutional restructuring to accommodate the changing needs;
- Assistance to small and marginal farmers in the establishment of self-help organizations which can (i) sustain agro-businesses on their own, (ii) channel more credit funds, and (ii) transfer technologies;
- Participation of NGOs in agricultural development programs.

### *Human resources*

- Development of human resources through education, training and motivation;
- Enhancement of the capability of women and youth to contribute more to agricultural and rural development.

## **2.15 Policy suggestions**

From the analysis and review, a number of policy packages have been identified for consideration.

### *Focus on under-developed areas*

The under-developed areas in the country should get priority for the production of suitable crops. Special development programs should be undertaken in the Barind and Madhupur Tracts, and also in extensive low-lying areas such as the Gopalganj-Khulna Bils, the Arial Bil, and the Sylhet Basin.

### *Promoting upland farming/rainfed agriculture*

Cropping patterns need to be reoriented and action for upland farming has to be strengthened in the north-eastern hilly region of Bangladesh. Related research and extension programs need to be undertaken immediately.

### *Regional approach to national agricultural research and planning*

There is significant disparity in the variation of cropping intensity in Bangladesh. For instance, in 1994/95, cropping intensity varied widely from 128% in Rangamati to 208% in Bogra district. Various studies suggest that there are also wide gaps between potential and realized yields for all crops. For instance, yield of potato in Bangladesh is only 11 t/ha although the yield potential, or achievable yield, has been reported to be as high as 40 t/ha (Rahman 1990). In another instance, the yield potential of the existing HYV of rice is more than 4 t/ha, but the average yield realized by the majority of farmers is only 2 t/ha. In the case of wheat, the gap is even wider. The yield potential of the HYV wheat is about 4 t/ha whereas the average yield at farm level is no more than 1.7 t/ha. Similarly, yield gaps also occur for other crops such as mustard, pulses and vegetables (Hossain 1999). Emphasis should be given to regional and short-term location-specific research that would involve exploration and identification of the

areas with great agricultural potential (intensification, diversification, etc.), rapid screening of local and improved varieties and development of production practices.

Technology interventions that are necessary to bridge the gaps in current and potential yields and to maintain production at a sustainable level are identified as follows:

*Seed quality*

The irony of seed quality is that today only 2-3% of the total requirement of seeds is met by certified seeds. With this amount, it is unlikely that the desired production can be achieved. National scientists believe that if 20-25% of the requirement can be provided through certified seeds, the volume of production could be increased substantially.

*Stimulating small-scale irrigation*

Irrigation is important for intensification of agricultural production. This is true especially for HYV, and is indispensable for accelerating boro rice cultivation during the dry season. Therefore, sufficient irrigation devices, including small-scale irrigation equipment, should be made available at the farmers' doorstep. For instance, small-scale, minimal cost, manually-operated irrigation systems could induce pulse farmers to provide partial irrigation to pulse fields.

*Provision of small agricultural credit*

Steps should be taken to provide adequate credit to farmers, particularly marginal, small and women farmers. Banking constraints with regard to timely sanctioning of credit have to be removed. For instance, the present pulse production in Bangladesh is solely dependent on traditional seeds, soil, land type, as well as time of planting. Further, since pulse production is not eligible for farm credit (Elias 1988), farmers have to depend on traditional practices and hesitate to use modern inputs such as fertilizer, irrigation and pesticides.

*Soil fertility*

Although Bangladesh is a fertile alluvial plain, soil fertility continues to decline due to a number of factors such as intensive cropping, low use of organic matter, and micronutrients and the unbalanced use of fertilizers. Scientists believe that production can be increased substantially through the balanced use of NPK, zinc and sulfur. The introduction of legumes and green manure into the cropping pattern and minimum tillage in combination with crop residues can contribute to a higher level of production and also improve soil fertility.

*Water resource management*

Bangladesh needs to adopt a balanced rational approach to flood management that combines both structural and nonstructural measures. Moreover, flood control and mitigation cannot be considered apart from other issues of water resource development. They should be part of an integrated water management plan embracing environmental concerns as well as various sectors of the economy. With better management of water resources, the gap between yield and production can be substantially reduced. The coverage of irrigation can be further expanded to dry areas. Considerable increase in yield is also possible under rainfed conditions in certain areas of Bangladesh.

## *Chapter 1*

### *Improved cultural practices*

Improved cultural practices are effective tools for further increase in production and yields. Timely planting is a critical factor for maximum yield realization in pulses and other crops.

### *Control of pests and diseases*

Management of pests and diseases is a prerequisite for increased production and crop productivity. The use of fertilizer, good seeds and irrigation together cannot ensure increased and sustainable production if timely measures for the control of different pests and diseases are not pursued.

### *Risk management technology*

Environment risks associated with the various agro-ecological zones such as frequent flood, drought, cyclones, tidal-bore, salinity, etc. constrain the potential of agricultural production. Technologies available for decreasing risks and measures to mitigate the losses from flood, drought and salinity can increase the production and yields.

### *Ensuring fair prices for products*

To provide fair prices for agricultural produce, a price support policy should be firmed up. Similar support may also be provided to farmers to increase the production of exportable agricultural commodities. A crop insurance policy may be helpful in this respect. For instance, most minor crops such as pulses, roots and tubers (e.g. sweet potato) are produced at the subsistence level. To increase the production of these nutritious crops, a cash cropping system is needed with an effective marketing system and infrastructure. In recent years, potatoes seem to have had a bright prospect in Bangladesh. But because of their perishable and bulky nature, farmers are often compelled to dispose of their produce immediately after harvest (the season of potato is very brief and the supply during the period of harvest always exceeds the demand, causing prices to drop). With the expansion of cold storage facilities, farmers can keep potatoes and wait for prices to rise.

### *Improving food habits*

The government should undertake a program by way of demonstration and propaganda through mass media to motivate the people to diversify their food habits.

### *Homestead gardening*

Homestead gardening and farming must be rigorously pursued to involve the maximum number of marginal farmers and small farmers to increase production of vegetables, fruits, spices, etc. in the homestead area.

### *Protection of productive agricultural land*

Agricultural land is being used for various industrial purposes in the country. Productive land needs to be protected from urban-industrial expansion.

### *Stabilizing population growth*

There are limits to the extent to which agricultural production can be increased, especially in the coming decade. It is important that population growth be stabilized if agricultural progress is to bring improved per capita welfare to Bangladesh.

## **2.16 A perspective on agriculture**

Considering the rapid population growth and limited non-farm opportunities in Bangladesh, agricultural growth will be the most viable alternative for broad-based participatory development. Export-led growth typical of many fast growing Asian countries may eventually pull the vast rural sector along, but the countries which have done well from the very beginning in providing food security for all are the ones with broad-based agricultural strategies. Since area expansion is no longer a feasible option in most parts of Bangladesh, future increase in local food production must come mainly from higher yields. Consequently, agricultural scientists and extension workers must find ways to further increase yields for crops. Failure to improve local varieties of rice with low-cost technology has also limited yield. In this respect, one avenue that remains open for attaining self-sufficiency in food is to improve the dietary habits of the people by favouring the foods made from animal products or derived from the nutritious crops such as pulses, roots and tubers. This will satisfy peoples' nutritional needs, while reducing the great dependency on cereal consumption. Hence, a crop diversification program should be adopted and minor crops should be considered.

This must be encouraged through renewed support to agricultural research. Sustainable innovations for productivity enhancement should receive prime attention. The development of bio-technology suitable for land-scarce conditions is a very important consideration in this regard. Crop varieties that are more resistant to pests and drought, and new varieties and hybrids better suited for various agro-ecological conditions will be in great demand. Farmers should be encouraged to adopt farming practices that are ecologically sound for their areas. Indigenous farming systems often contain a wealth of environmental knowledge, which needs to be assessed and adapted. More funds have to be allotted to smallholder needs and more incentives given to scientists.

Appropriate technology must help increase not only resource productivity but also labour productivity. This implies drastic changes in the priorities, location, content and coverage of current agricultural research. Measures need to be taken to reverse environmental degradation. Agricultural policies that vary from region to region should reflect different regional needs. Resource inventory and land-use potentials should provide answers to the particular regional needs. Classifying land according to best use will determine variations in infrastructure provision, support services, promotional measures, regulatory restrictions, fiscal subsidies and other incentives. A reorientation in public intervention should provide a framework for this.

The brief analysis of Bangladesh's agriculture presented in this chapter delineates a dominant sub-sector that is obviously struggling, but one which is making progress in its efforts to modernize. As such, any characterization of Bangladesh as a bad performer in achieving food self-sufficiency is inaccurate and misleading. It undermines the past achievements, distorts the realities of the present and discourages the future potential. We hope that under responsible leadership and with full support from the people, farmers and scientists, a modern productive agriculture for Bangladesh and improved welfare for its people are attainable. Of course, there are many serious constraints, but they should not be too difficult to overcome as they are not unique from those in other developing countries. There is now widespread consensus on what needs to be done, based on years of international agricultural development experience.

# **1. General Indicators**

**Table 1.1 Population: agriculture, non-agriculture and total, 1961 - 2001.**  
(*'000 persons*)

Year	Agriculture	Non-Agriculture	Total
1961	45,994	6,731	52,724
1962	46,928	7,125	54,053
1963	47,882	7,535	55,417

Note : (a) Culturable waste = Area suitable for cultivation, but lying fallow for more than a year.

(b) Current fallow = Area already brought under cultivation, but not cultivated during the year.

(c) Total cropped area = Sum of the net cropped area and the area sown more than once.
