# **Agricultural reform: Which type of models do we need?**

**Michiel A. Keyzer**

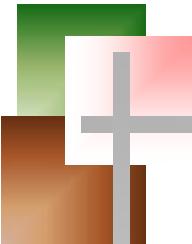

Centre for World Food Studies (**SOW-VU**)

Vrije Universiteit Amsterdam

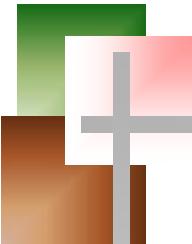

# Agriculture related AGE-modeling at SOW-VU (1)

- World models
  - MOIRA (1979, for Club of Rome) : International equilibrium, 127 countries, 2 commodities, 12 income groups per country
  - BLS (1988, with IIASA) : International AGE, 10 commodities, 34 countries/regions, 2 income groups per country

## Agriculture related AGE-modeling at SOW-VU (2)

- National and regional:
  - Completed: Thailand (1981), Bangladesh (1986), Indonesia (1990), Nigeria (1997)
  - Ongoing: EU-15 (1991-present, originally with LEI&CPB, now with CPB)
  - Ongoing: Ghana, China
- Texts:
  - Gunning & Keyzer (1995) Handbook Dev. Ec., North Holland
  - Ginsburgh & Keyzer (1997/2002), MIT Press

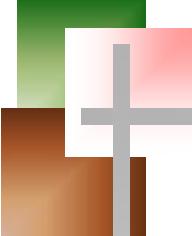

# Which type of models do we need?

## Overview of presentation

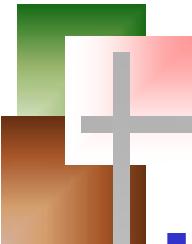

Current demands of agricultural policy analysis: three topics

- #1 Improving capacity to analyze current CAP-reform
- #2 Accounting for present trends on meat and feed markets
- #3 Representing spatial heterogeneity: land, population density, transport

# #1 Improving capacity to model CAP-reform

- Importance of agriculture in EU
  - all key agricultural policies under Common Agricultural Policy (CAP)
  - agricultural budget of around 40 billion Euro by far largest item on EU budget
  - even WTO negotiations on agriculture are led by agricultural commissioner
  - modalities of CAP central item in accession 10 new EU members
  - CAP-reform currently under discussion: Mid Term Review

## (#1 Improving capacity....) Mid Term Review (MTR)

- MTR, July 2002 proposal:
  - Area & livestock premiums replaced by farm-specific, land-tied payment rights
  - Cross compliance: nitrate directive, good agricultural practice, ...
  - Payments rights only tradable with the plots
- MTR, January 2003 legal texts, same but:
  - Land-tied payment rights tradable independently from land
  - But only one payment right on a hectare
  - All land not under permanent crops is eligible

## MTR decoupling scenarios with GTAP

- Joint outputs obtained as derivatives of restricted profit function with factor inputs (labor, land, equipment)
- Current Agenda 2000-package of CAP (v. Meijl-v.Tongeren,2003)
  - Subsidy inclusive prices in objective
  - Policies among resource constraints: milk quotas, manure quotas, set-aside (GEMPACK)
- Payments under MTR fully decoupled to fixed factor, and tradable
- GTAP-model cannot explicitly accommodate
  - Flat area subsidies by class of commodity (arable crops vs others)
  - Cross compliance requirements
  - Modalities of limited tradability of payment rights among farmers

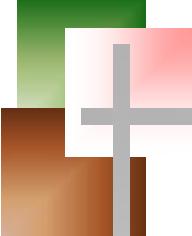

## MTR requires farm management type of model (1)

- Crop yields by category and land type (e.g. for cross compliance)
  - depend on fertilizer/ha, pesticides, labor etc.
  - positive intercept reflecting natural fertility (soil)
  - ceiling reflecting natural potential (climate, soil)
- Land requirement by crop: land balance
- Animal yields by breed and technology type (extensive, etc.)
  - depend on feed/head (roughage, composite feed)
  - negative intercept reflecting basic metabolic requirement
  - ceiling reflecting potential of breed, under assumed technology
- Feed requirement by animal: feed balance (incl. roughage)

=> **Farmer to solve revenue maximizing NLP, preferably by farm type, with yield functions, and land and feed balances**

## MTR requires farm management type of model (2)

- Farm management type of NLP can account for effect cross compliance: e.g. cattle farmer may
  - Sell payment rights and stop farming
  - Sell herd, keep payment rights and mow grass
  - Buy additional payment rights and develop multifunctional agriculture etc.
- Suitable AGE-formats to embed NLP, allowing for primal constraints, (see Keyzer, Merbis & Van't Riet, in CEC, 2003):
  - Negishi welfare program (welfare weights to meet budgets)
  - Full format (budgets in constraint set)

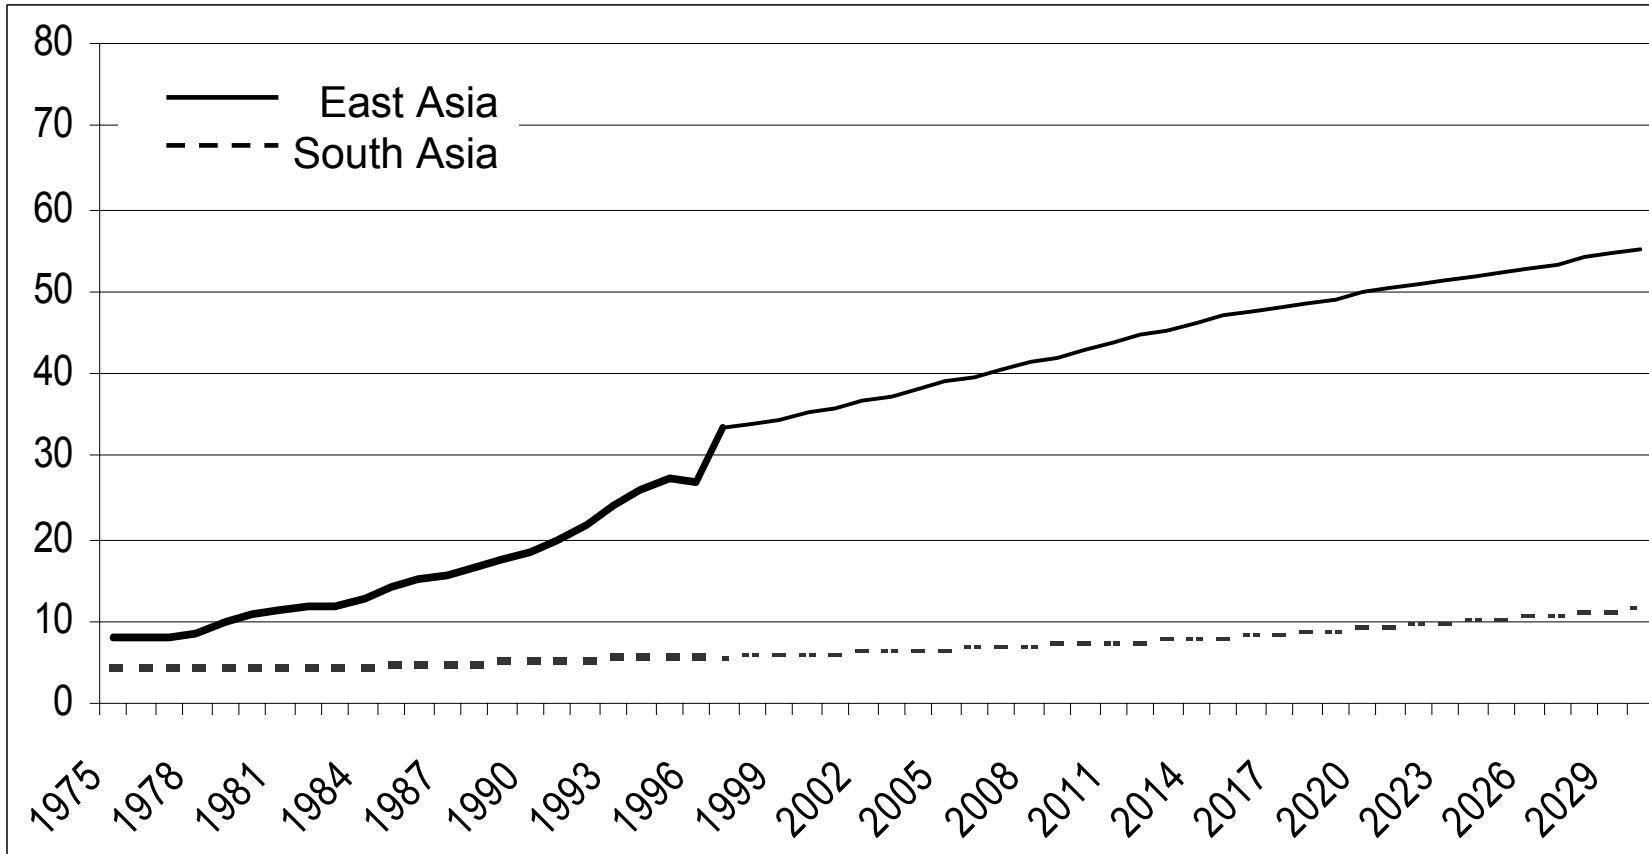

## #2 Accounting for key trends on meat and feed markets

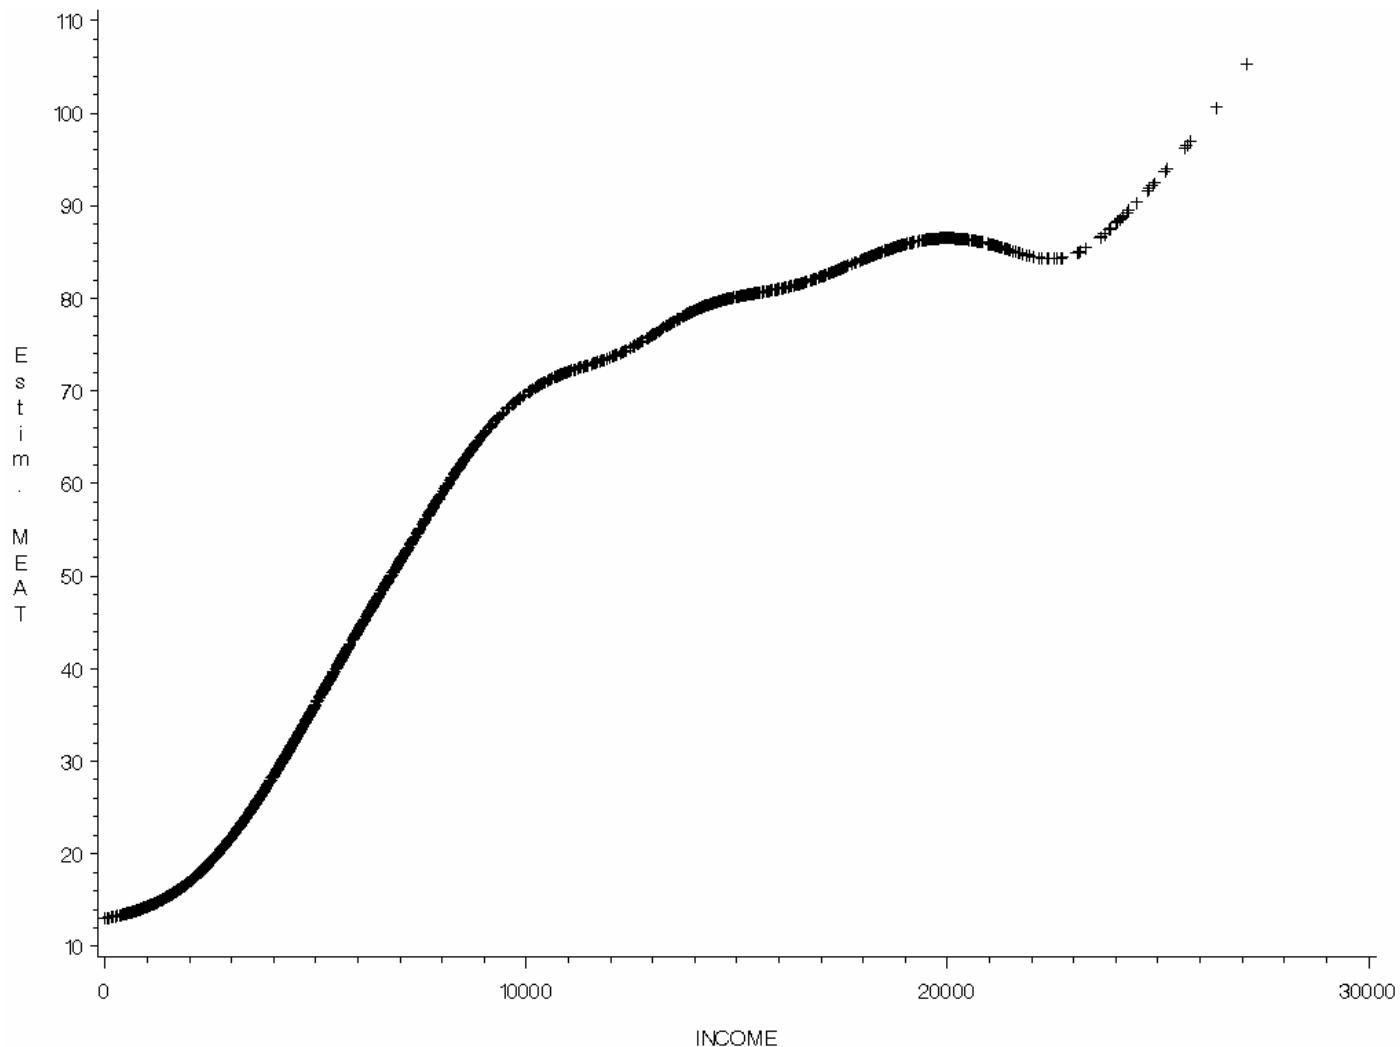

Stylized facts on meat and feed demand:

- with increasing per-capita income, especially in Asia, consumer demand is shifting towards meat and dairy
- in LDCs livestock production in Asia currently relies mainly on traditional technologies based on rangeland, household waste etc.
- expansion only feasible with more feed intensive techniques

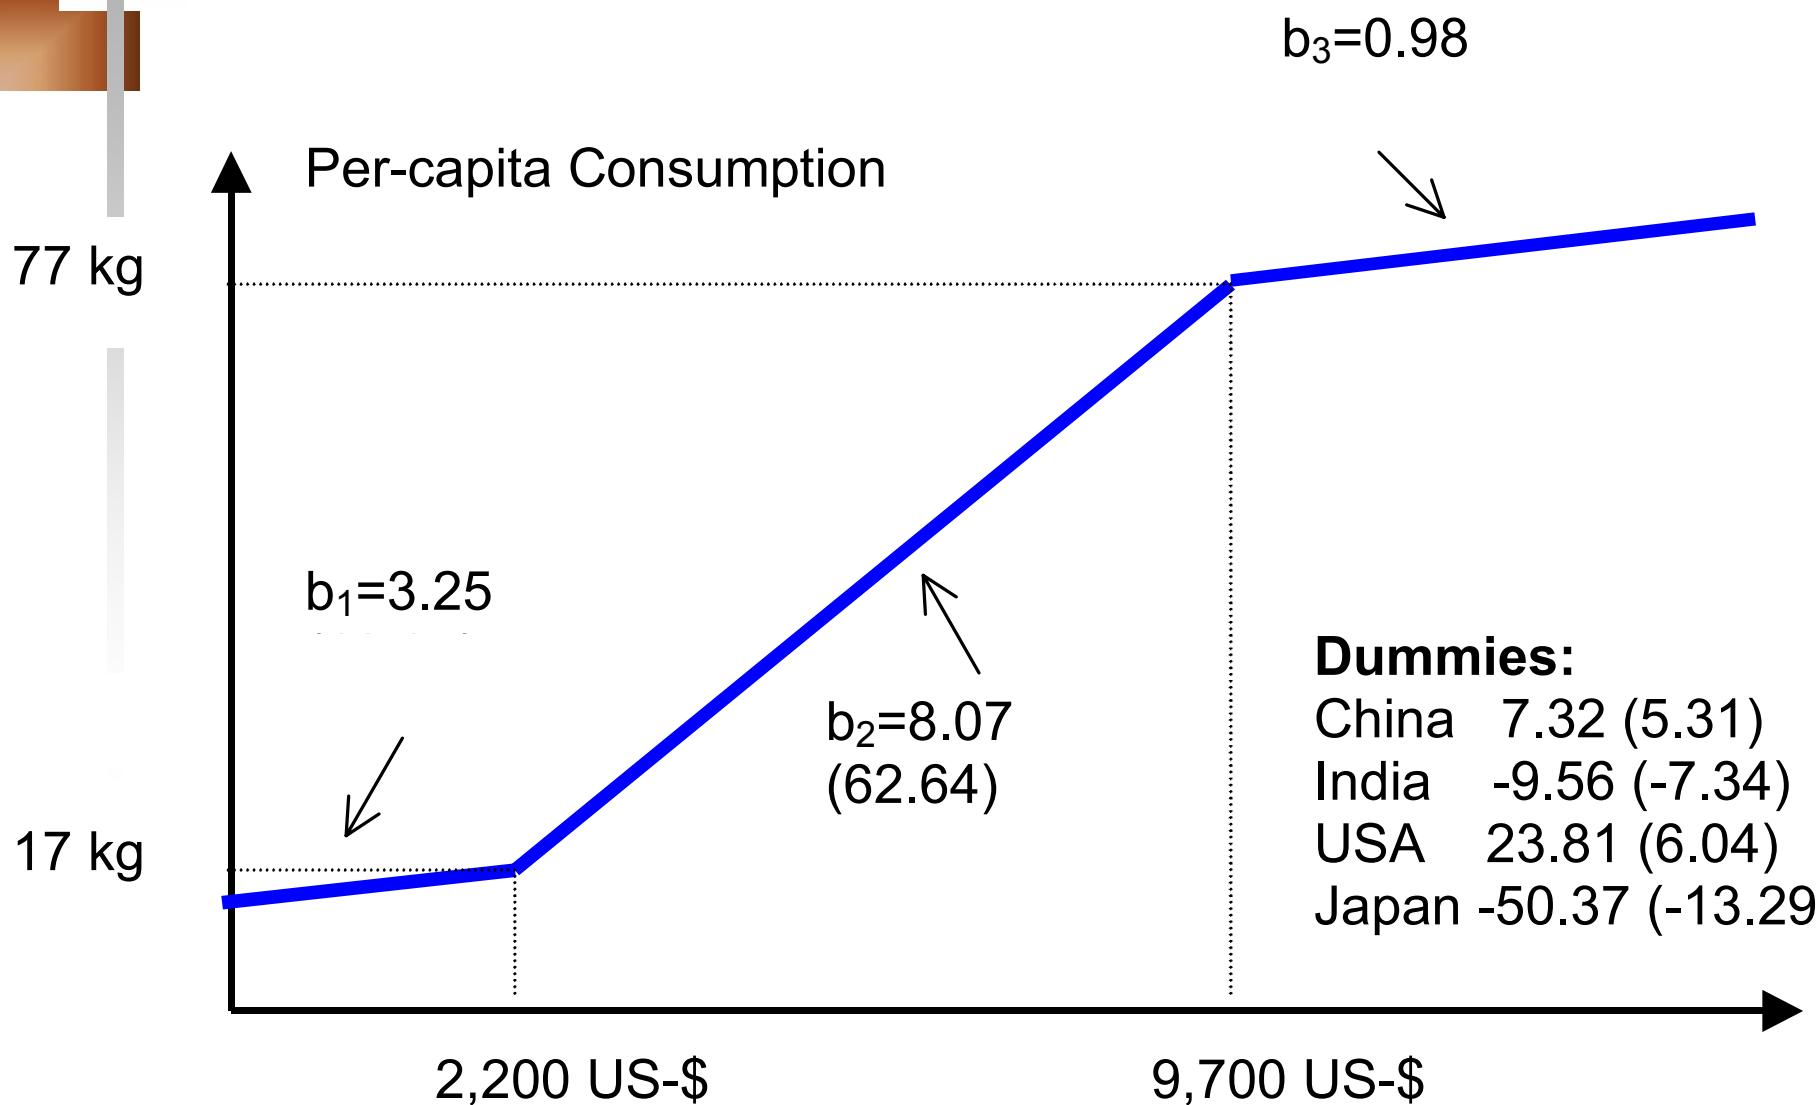

## Per-capita meat consumption in Asia (data and FAO projections)

## Non-parametric estimation of meat demand and per-capita income (125 countries, 1975-1997)

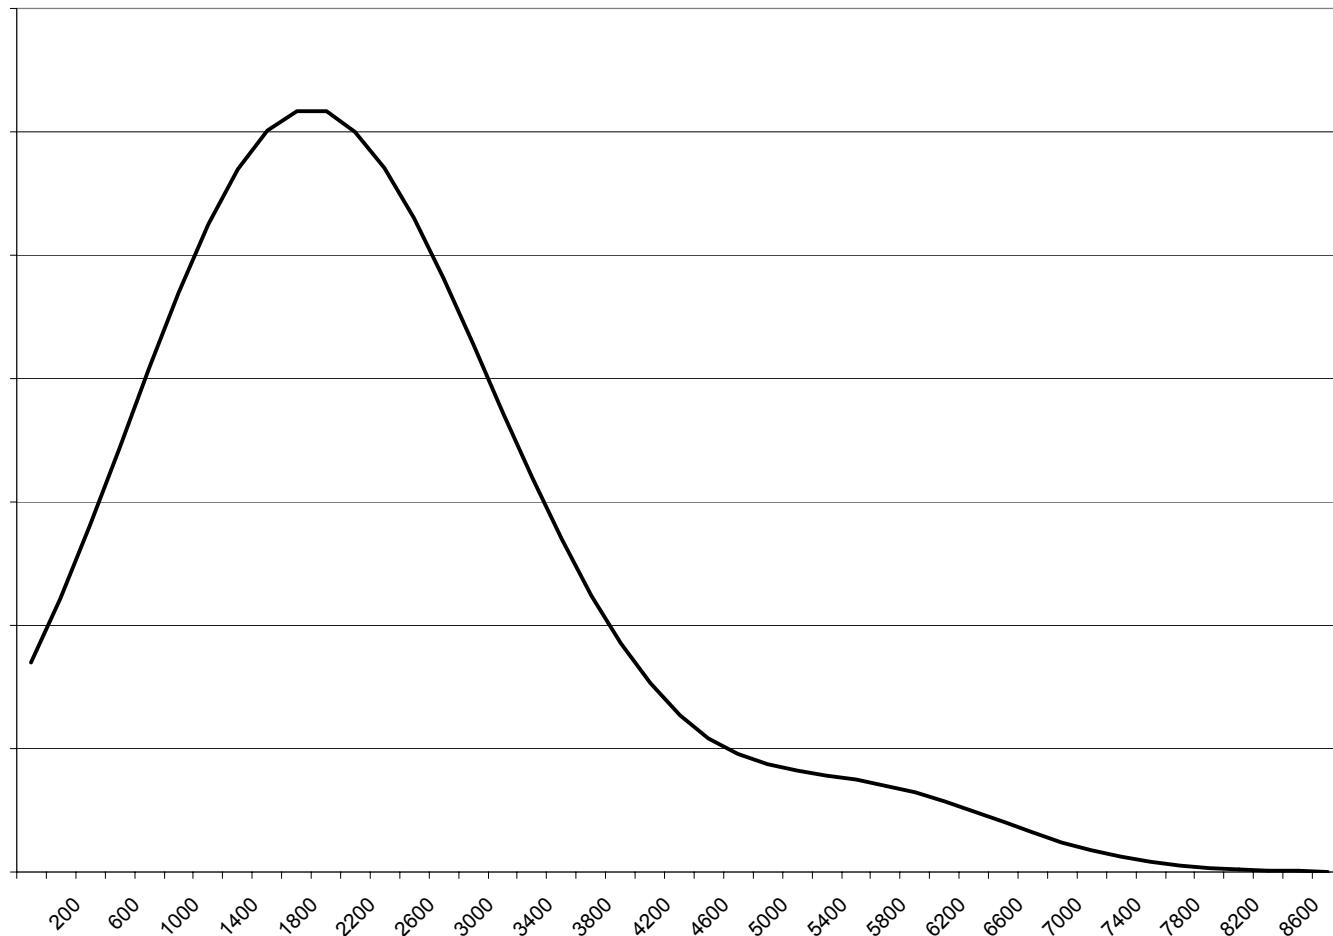

## GLS-Estimation of kinked meat demand function (125 countries, 1975-1997) (1)

## GLS-Estimation of kinked meat demand function (125 countries, 1975-1997) (2)

- Apply kinked meat demand to income distribution
  - In many Asian countries, large segments of population are still to enter high propensity regime (middle bracket)
  - In other parts of the world impoverishment causes segments to adjust consumption (enter middle bracket from right, or shift to left bracket)

## From Deininger/Squire to a smooth income distribution (China 1997) (2)

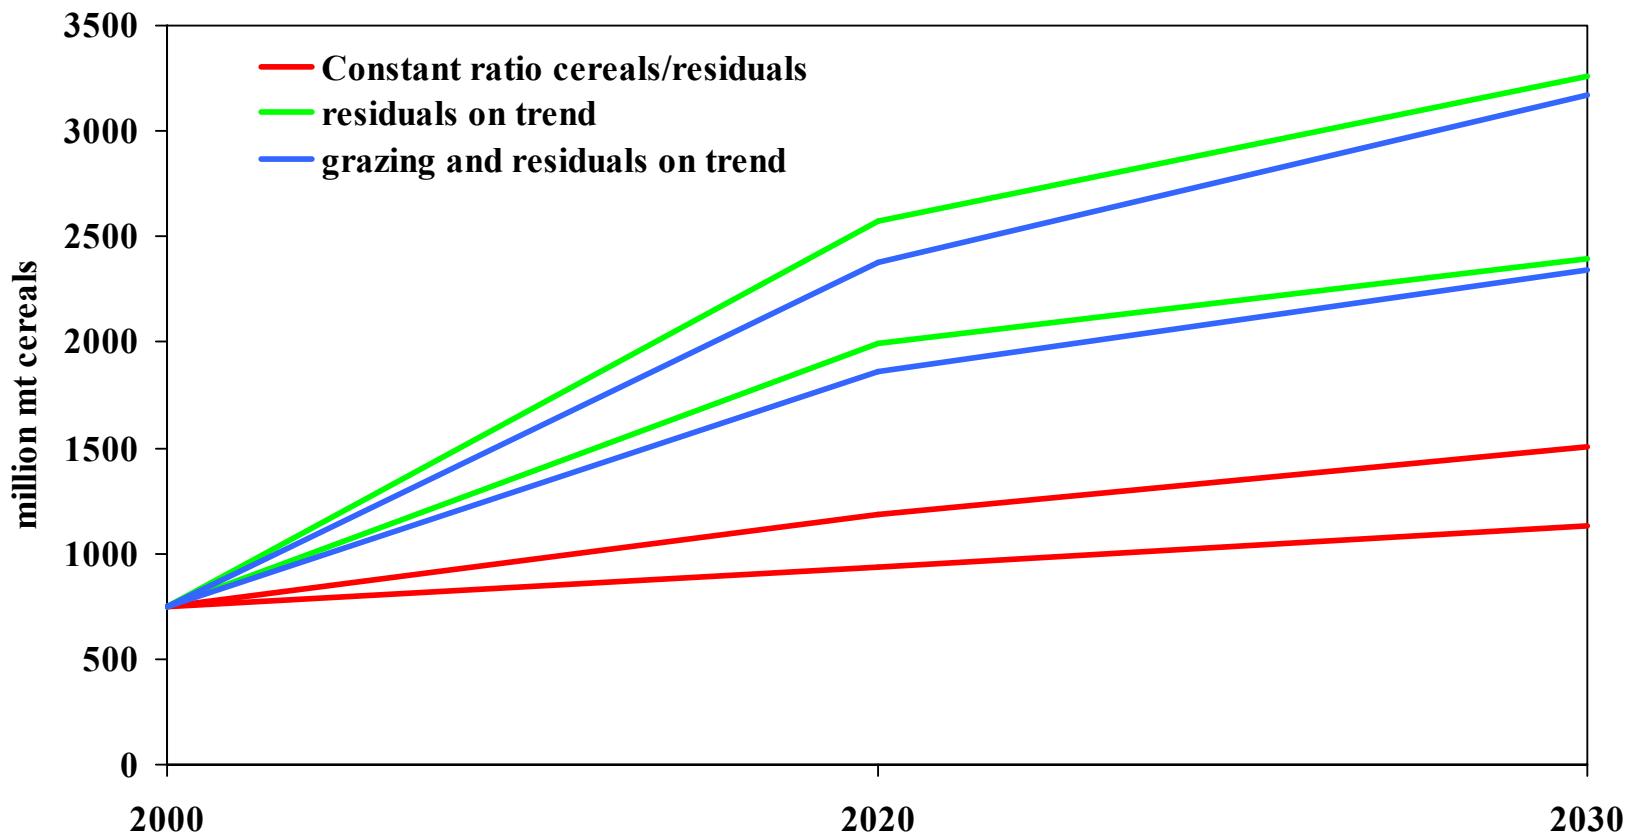

## From meat demand to feed demand

- Three general types of animal systems
  - grazing systems
  - mixed production systems
  - intensive production system
- Within intensive system
  - Backyard production largely relying on household and crop residuals
  - Specialized households
  - Large commercial units
- How does composition of animal systems change in response to increased meat demand ?
- How does cereal share in feed change in response to increased meat demand?

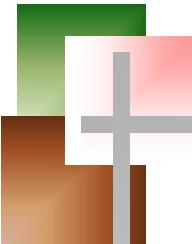

(#2 Accounting for key trends ...)

## Projections of feed demand

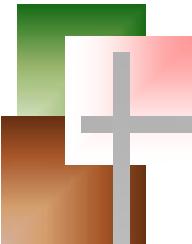

## Key trends on meat and feed demand: findings

- Allowing for income distribution effect under three consumption regimes leads to significantly higher projections for meat demand
- Increasingly, limited availability of residual feed in developing countries causes shift towards modern technology and raises demand for cereal feeds even further
- The magnitude of effects on cereal markets is dramatic:
  - Meat demand/technology shift: up to +1,800 mill. t. in 2030
  - Climate Change (IIASA, 2001): - 105 mill. t. in 2080
  - GMOs: no large effects on yields expected
- Environmental consequences of increased meat production (in particular emissions of Methane and Ammonia) should be looked into, especially for China

## #3 Representing spatial heterogeneity: land, population density, transport etc.

- Issues:
  - Spatial aggregation problem in large countries such as India or China, also worldwide
  - TRQs require linking countries bilaterally, while accounting for transport costs, and without recurring to trade matrices
- Here, short discussion on the scope for constructing large scale spatial equilibrium model with transport costs
- General message: it is now possible to construct spatially explicit equilibrium models
  - datawise: population density maps (Deichman),  
digital elevation maps (DEM)  
satellite images (NDVI for crops)
  - Transport modeling less data hungry at fine scale
  - Hence, it now pays to work on algorithms

## (#3 Representing spatial heterogeneity...)

# Large scale spatial equilibrium (1)

- Objective : Find equilibrium supply, demand, flows and price on a map
- Tool : A new algorithm to solve a large scale, spatially explicit welfare program
- Advantage : Integration between disciplines: hydrology, soil science, transportation, regional sciences, international trade ...

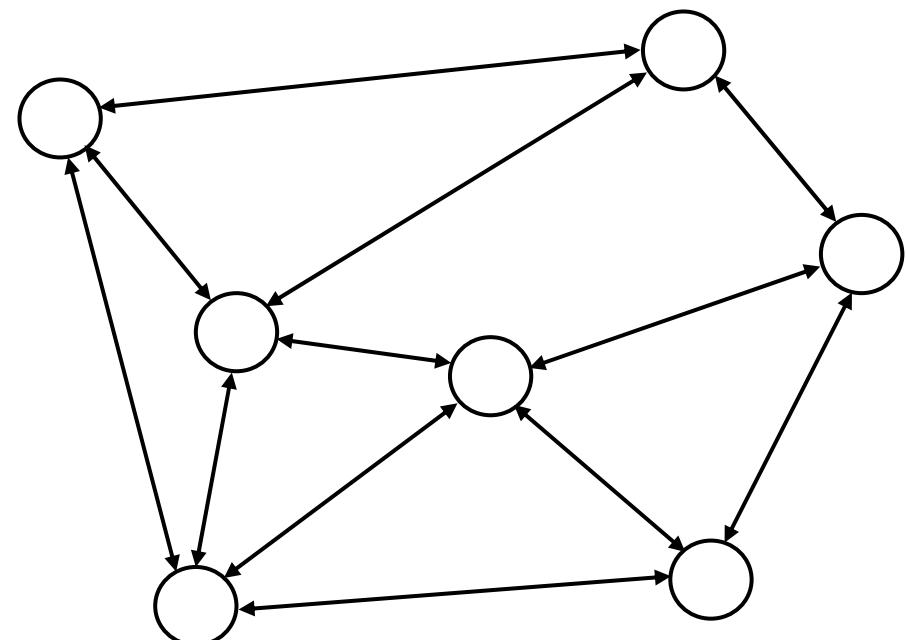

## Large scale spatial equilibrium (2)

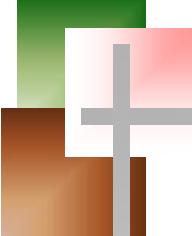

- Relevance to development
  - assessment potential of the areas
  - construction poverty maps
  - infrastructural planning
- Scientific relevance
  - interdisciplinarity
  - algorithms not available (in civil sphere)

## Spatial equilibrium versus Spatially explicit equilibrium

### Spatial equilibrium models

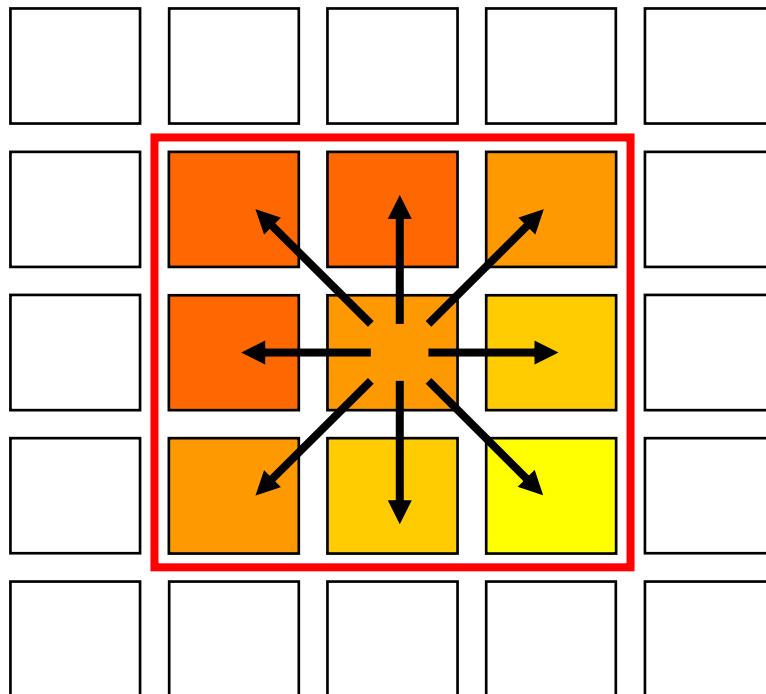

- Connect districts, or nodes in a network
- Not spatially explicit

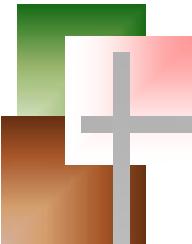

## (#3 Representing large countries...) Spatially explicit flow model

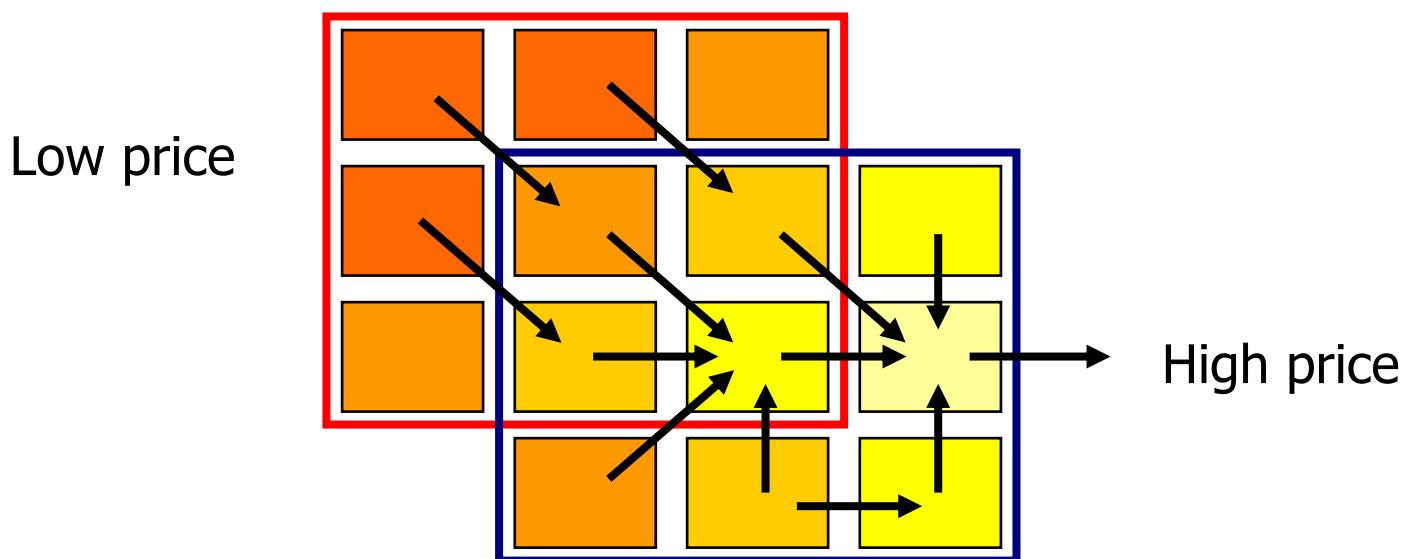

Allows for all possible flows on the Union Jack grid

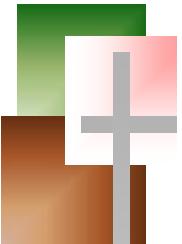

## (#3 Representing large countries...) Spatially explicit equilibrium model

- Key algorithmic principle: gravity driven flow
- Gravity : water does not flow uphill
- Transport : goods never flow to lower price

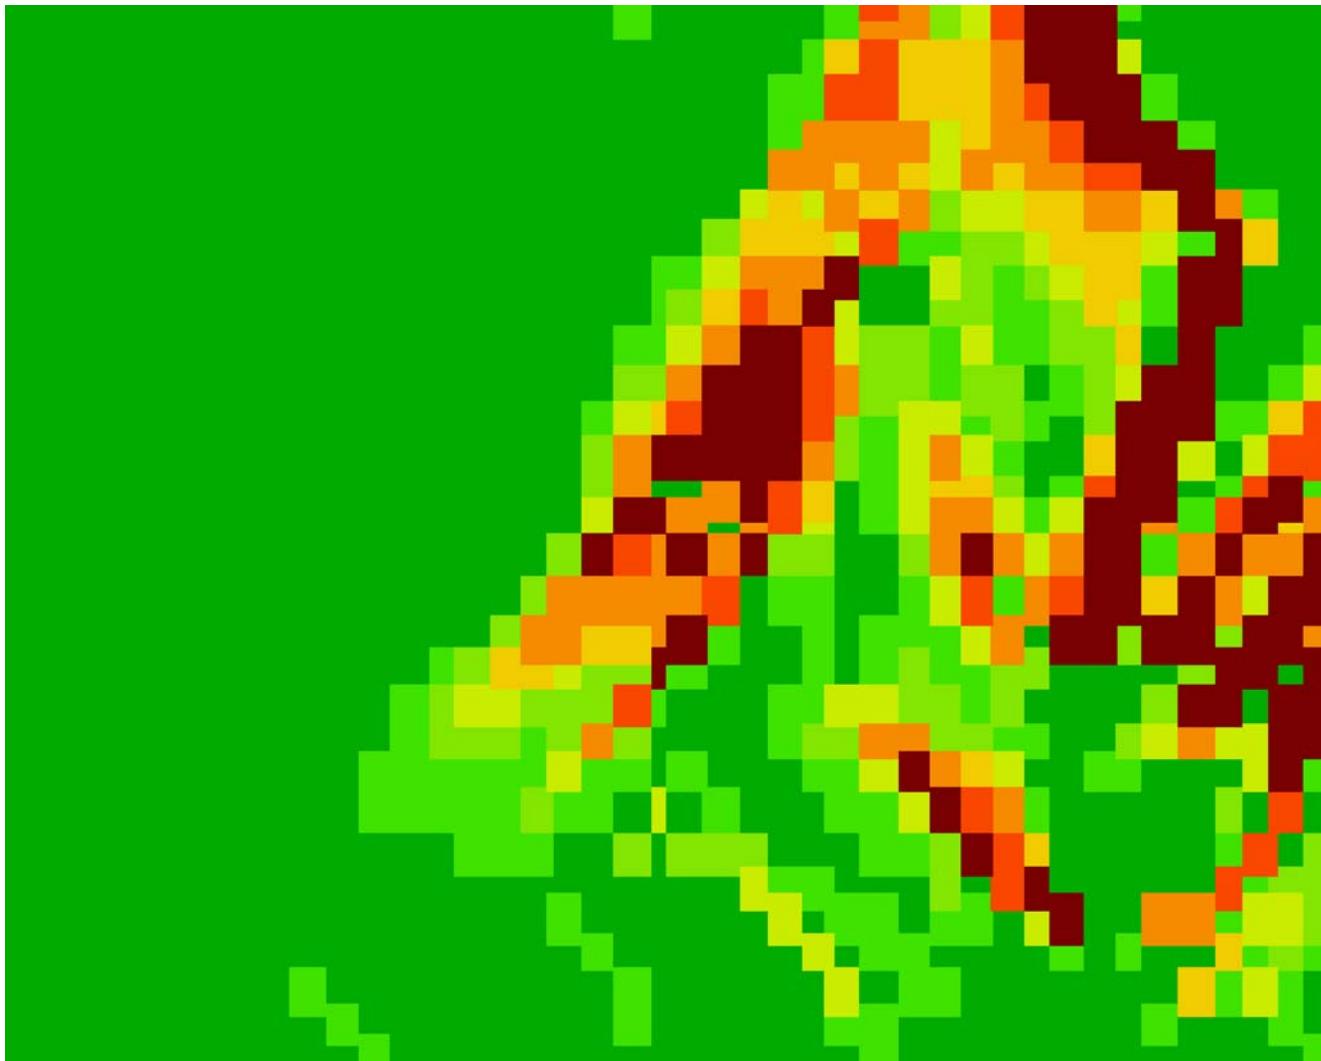

## Application to China

- Spatially explicit welfare model
- Exogenous variables
  - production map cereals
  - population map
  - tariffs and world market prices cereals
  - freight costs per ton
- Study world market price penetration
- Grid of cells of 10-by-10 km = 93125 cells (markets)

(#3 Representing large countries...)

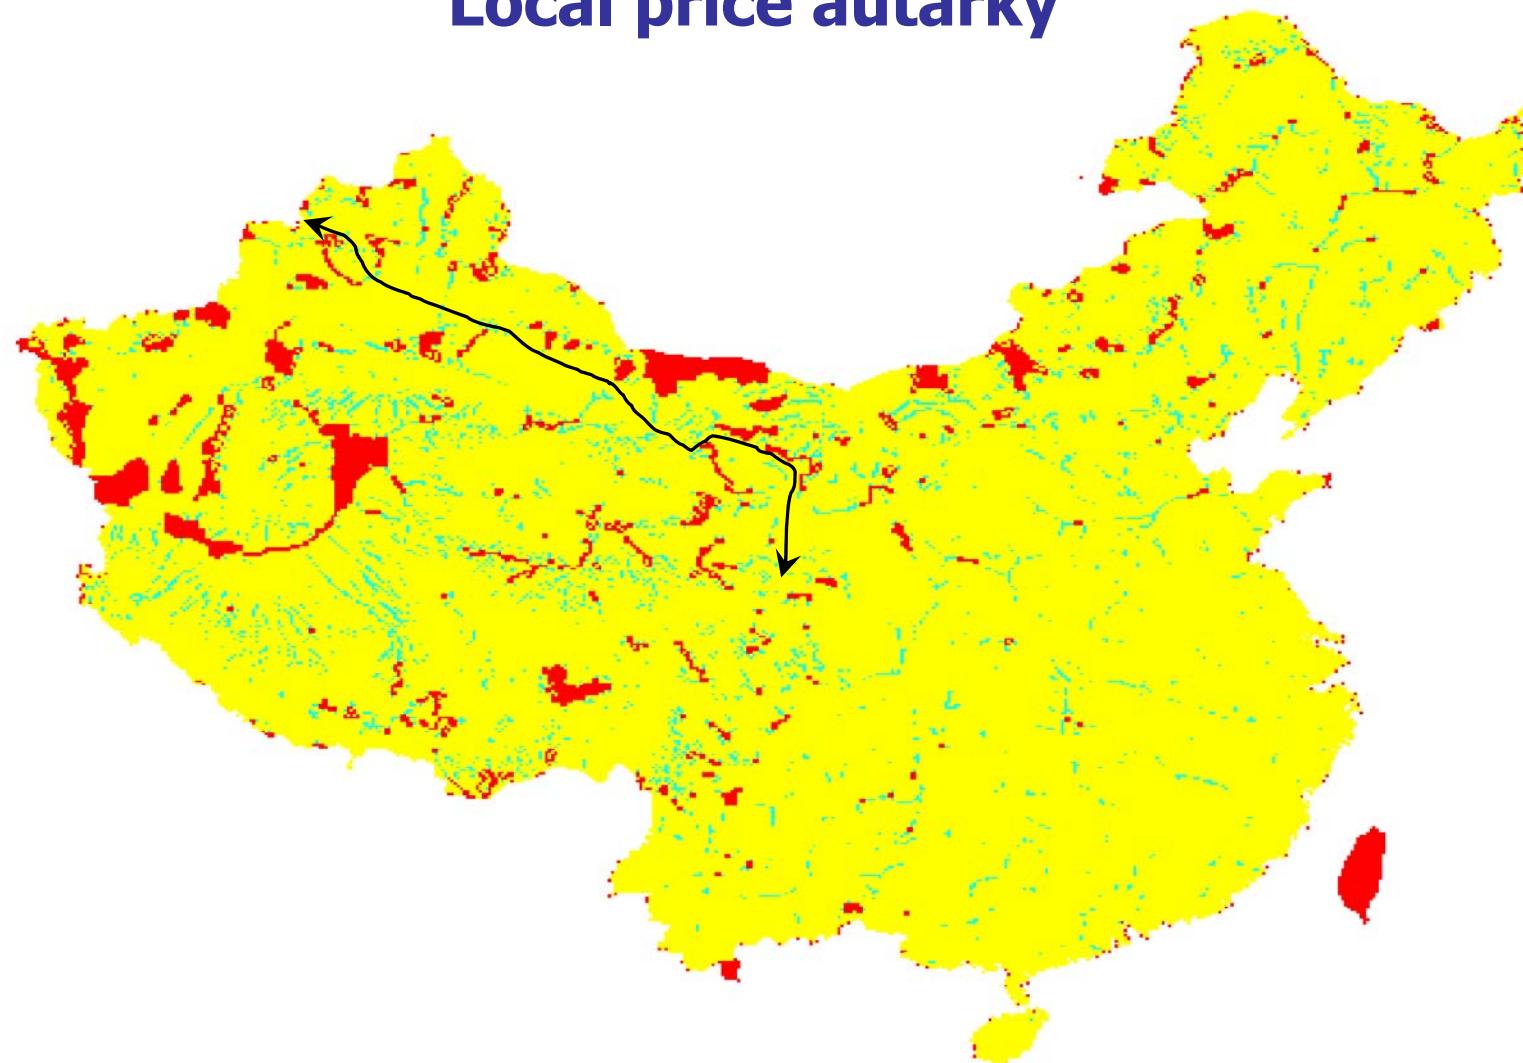

## Zooming in on individual markets

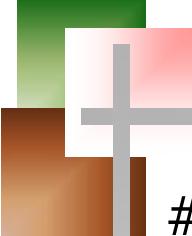

## Post-optimal calculations

- Under alternative international trade regimes, identify
  - Areas served by imports (quantity flows)
  - Unconnected or autarky zones (no price links)

(#3 Representing large countries...)  
**Local price autarky**

- ■ ■ Local autarky
- ■ ■ Isolated points and lines
- ■ ■ Linked areas

## Conclusions

- #1
  - (a) MTR representation requires NLP with explicit land and feed balances
  - (b) These primal constraints are naturally embedded in Negishi or full format AGE
- #2
  - (a) Trends in meat demand can be accommodated through kinked demand function, and some representation of income distribution within country
  - (b) Generating associated trends in feed demand calls for explicit feed balances, and distinction of livestock systems by intensity
- #3
  - It is possible to generate a meaningful spatially explicit equilibrium, and equilibrium with “very large” number of geographical units to deal with spatial heterogeneity
