Fiscal Policy Reforms in Senegal. Single Country CGE Analysis with highly desegregated SAM

Pierre Boulanger¹, Hasan Dudu¹, Emanuele Ferrari¹, Alfredo Mainar¹

This is a preliminary draft. Please do not quote version 15.04.2017

1. Introduction

The Emerging Senegal Plan (*Plan Sénégal Emergent*, PSE) launched a new development model which should allow the acceleration of the economic and social development of Senegal, in the medium and long term (2035). The aim is to accelerate growth. The target set over the period 2014-2018 is between 7 and 8%. This plan mentions public finances as a lever for action, particularly a sustained mobilisation of fiscal resources (République du Sénégal, 2014a). Should be borne in mind that Senegal is a member of the Economic Community of West African States (ECOWAS). Thus Senegal faces fixed exchange rate and no control over its monetary policy (managed by the Central Bank of West African States). Consequently, fiscal policy is the main lever to achieve political goals. In Senegal, the level of taxation as a percentage of GDP (around 20 % in 2014) is consistent with the average of countries of similar development level (see appendix). A recent study assessing the tax potential of Senegal considers that the increase in tax revenues is 2.8 percentage point of the GDP, i.e. presents a potential of 22.8 % (Ba and Diagne, 2016). Building on existing analyses, the authors stress that the agricultural share of the GDP has a negative effect on direct and indirect taxes. However, if agriculture contributes to about 16 % of the GDP of Senegal, the relative decline in the contribution of the agriculture sector to GDP represents an opportunity to enhance mobilisation of public resources because agriculture is a sector which is difficult to impose (AfDB/ADF, 2010).

The programme on acceleration of the pace of Senegalese Agriculture (*Programme d'accélération de la cadence de l'agriculture sénégalaise*, PRACAS) is the agricultural component of PSE to increase food safety. In particular, it aims to reduce the trade balance deficit and set up ambitious goals, including self-sufficiency in rice in 2017, and high production targets in strategic sectors for 2017, i.e. onion, peanut, fruit and vegetables. In addition, the PRACAS mentions as key the upgrade of the seed, water management, equipment, modernisation of the rural world, etc. (République du Sénégal, 2014b). It calls for rethinking the subsidy policy in the context of PRACAS accompanying measures, with a focus on fiscal incentives of investments and VAT exemption on inputs. Focusing on the predictability of public expenditures on food and nutrition security in Senegal, EU (2015) highlights the current weight of subsidies in agriculture (inputs and price). These reduce the possibility of financing alternative measures. In 2014, agricultural input subsidies capture 12 % of food and nutrition security expenditure (49 % in 2012) while the PRACAS draws up a strategy of reducing such subsidies. In this context, the government plans the gradual reduction of input subsidies, with the objective that they decline from 0.5 % to 0.3 % of GDP (three-year average). In fact, a decrease of 0.56 % (2012/14) to 0.24 % (2013/2015) can already be observed.

EU (2015) points out some fiscal expenditures (tax exemptions) corresponding to indirect subsidies to consumers, in particular the exemption of VAT and customs duties on food imports (e.g. rice, wheat, milk and dairies) and agricultural inputs (seeds, fertilisers, agricultural machinery and equipment,

¹ European Commission, Joint Research Centre (JRC), Seville

<u>Disclaimer</u>: The views expressed in this paper are the sole responsibility of the authors and do not necessarily reflect those of the European Commission

etc.). Resulting lower input and food prices may represent a high cost for public finances. Therefore regular estimates of tax expenditures and their inclusion in the initial budget law are recommended. IMF (2017) sheds some light on the low taxation of the agricultural sector despite a broad base of possible contributions. Indeed it is not clear if a direct taxation would be optimal. This later would limit the upgrading/expansion of crops of greater added value and would require an assessment on the Senegalese economy and more specifically in the agriculture sector of a potential tax reform. The above-mentioned IMF study stresses the need for indirectly taxing the sector on the basis of its potential to contribute to the State budget, and proposes three lines of action:

- Taxation of land tenure in rural areas (with exemption of agricultural land for productive purposes to foster the modernisation of farm holdings);
- Income tax exemption (with few thresholds, especially for higher income from property and agricultural sectors);
- Consumption taxes (e.g. VAT).

Appropriate taxation requires land reform as well as skilled technicians. It appears that property taxes are underused in Senegal although they are promising as progressive, administratively feasible and increasing along with urban sprawl. Finally, it should be stressed that real estates are is effective and fair form of taxation (Norregaard, 2013).

The aim of this paper is to quantify some fiscal policy reforms in Senegal support agriculture and other sectors essential to the food and nutrition security (FNS). Section 3 presents the methodology. Section 4 and 5 explains the scenarios and results, respectively. Section 6 concludes.

2. Methodology

The model used in this study is a comparative static variant of the STatic Applied General Equilibrium model (STAGE) (McDonald, 2007) specifically extended for the context of the developing countries (STAGE-DEV)(Aragie et al., 2017). The model is thus calibrated to 2014 Senegal SAM that is built for the purpose of this analyse.

2.1 STAGE-DEV: A STatic Applied General Equilibrium model for Developing Countries

To properly model agriculture and food security issues in Sub-Saharan African (SSA) countries, a model should be able to depict the dual roles of semi-subsistent agricultural households, which play the non-separable double role of producers and consumers. Other SSA peculiarities a model should rigorously tackle relate with structural rigidities in economies, especially labour market and factor segmentation; high level of unemployment/under employment, particularly in rural areas; high use of time for non–productive activities (i.e., fetching water); substantial population and labour force migration, etc.

The introduction of a Home Production for Home Consumption (HPHC) module within STAGE is a crucial added value of the STAGE-DEV. Indeed HPHC is explicitly modelled to account for the non-separability of the dual roles of producers and consumers. The consumption is modelled with Constant Elasticity of Substitution-Linear Expenditure System (CES-LES) nested structure that allows substitution between "broad" commodity groups (i.e. in the top nest) which are subject to subsistence consumption constraints, while at the lower level households can substitute between the component commodities (e.g., HPHC and consumption from market) of the "broad" commodity groups.

In addition, we model small-holder agricultural production by exploiting the multiple-output structure of STAGE. The original STAGE model allows for a simple modelling of multiple product activities through an assumption of fixed proportions of commodity outputs by activities. This represents a by-product assumption, with commodities differentiated or undifferentiated by the activities that produce them, using CES aggregation to define composite variants of differentiated commodities produced

domestically (the same as in Lofgren et al., 2002). STAGE_DEV adds the option that activities can vary their output mixes in response to changes in commodity prices, by introducing CET functions that modify the shares of commodity outputs in response to price changes. The formulation adopted, following Punt (2013), allows the user to define activities for which commodities are differentiated or not and activities that produce fixed or variable output mixes.

Furthermore, an endogenous labour supply decision of households is introduced as "quasi-activities of leisure" that produce "quasi-commodities of leisure" for each household type (not activated in the present simulations). These activities use only labour from the paired households and the leisure quasi-commodity is consumed only by the same households. A satellite account keeps track of factor ownership, such that labour available to households for activities within the production boundary, i.e., labour sold on the labour market, plus labour used to produce leisure. Following the standard logic behind the CGE models, the price of leisure commodity is defined by its costs (which is the cost of labour used to produce it) and hence labour commodity can be assigned an unambiguous price and hence valuation. Thereafter leisure is treated as a standard commodity in the model. Lastly, the labour market closures are extended to include labour used by the leisure quasi-activity.

The model also introduces household migration and factor segmentation. Both use the same method, a generalisation of the method by McDonald and Thierfelder (2009), used in Polaski et al., (2009), further refined by Flaig (2014) and Aragie (2015). Migration and segmentation account for persistent urban-rural and regional wage differentials, farm and off-farm wage disparity and continuous urban-rural and internal migration. In both cases, physical units of labour are allowed to transit across regions and/or skill types according to constant elasticity labour supply functions. The factor ownership matrix is updated after the simulation to accommodate migration and segmentation effects.

2.2 A disaggregated SAM for Senegal in 2014

The use of STAGE-DEV to simulate policy changes requires a Social Accounting Matrix (SAM). the most recent disaggregated and possible. A SAM, a portrait of the economy of Senegal for the year 2014, and the structure of which is presented in Table 1 has been constructed from the sources indicated below.

 Table 1. Basic structure of flows in the Senegal SAM 2014

Source: Own compilation

HPHC concept is introduced in the SAM by assuming that households also have a "production component". Besides the classic Representative Household Groups (RHG) that collect household behaviour as consumers of goods and services and as providers of factors of production (and receptorcontributors of transfers), in Senegal SAM 2014 new accounts are presented showing the behaviour of households as units of production of commodities. These accounts incorporate the economic behaviour of households as producers of food commodities (agricultural, livestock and fish products for food). This requires also separate accounts for commodities produced by these households for own consumption (HPHC as input or as a final product) and other marketed commodities (produced both by households and by conventional productive activities). Rows of these commodity accounts reflect HPHCs use as intermediate inputs in the productive activities of households and their consumption in final demand of households (RHG). Their row sums must be equal to the sums of the columns that summarize the contributions of the activities of households to each of these goods. Similarly, columns of the households activities show how they use inputs (HPHC and marketed), while rows show the destination of their production as inputs, own-consumption goods or marketed commodities. It is necessary to point out that households considered as producers have been broken down regionally (one household category for each region considered), while commodities produced are taken at national level in unique accounts. The breakdown of commodities and activities is summarised in in Table 2.

The regional breakdown in the Senegal SAM 2014 is based on administrative regional division of the country (allowing subsequent aggregations, if necessary to configure Agro Ecological Zones, AEZ). Thus, the country has been divided into 14 regions. This regional breakdown has been applied to both households, as productive units or activities, and households, as institutional units. In terms of agricultural production, the SAM accounts for three types of production agents: there are 14 household agricultural activities (ahf), one per each region, that produce 9 *subsistence commodities* not marketed and consumed at home, and 9 *marketed commodities*. The classic activities sectors (representing the market oriented larger holder producers) produce food and cash crops at national level.

In order to form the RHG, households as institutions have been further disaggregated into rural and urban, according to the area of residence. Also, in Dakar region, the urban part has been broken down by income quintiles. As a result, the Senegal SAM 2014 contains 33 RHG (an auxiliary account for rest of the world owners of labour factor is used too), allowing for a good analysis of redistributive aspects and specific impact of different policies.

Three types of labour are considered: skilled, semi-skilled and unskilled labour. Each labour factor is also regionalized, for the fourteen regions of reference plus a Rest of the World account. Hence, the SAM takes into account 45 different types of labour. Regarding capital factor, it has been split in land, livestock, agricultural and no-agricultural capital.

Fiscal issues can be analysed incorporating a split in taxation, so the SAM includes specific accounts for taxes: direct, indirect (production), sales (commodities, including VAT), factor and import taxes.

In summary, Senegal SAM 2014 consists of 209 accounts: 54 activities (14 of them accounts of households as producers) producing 53 marketed and 9 HPHC commodities using 3 types of labour (skilled, unskilled and semi-skilled) in 15 regions (45 labour accounts in total), 4 types of capital (agricultural, non-agricultural, land and livestock), 5 types of taxes (direct, indirect, sales, factors and imports), 33 regionalized RHG and one account each for margins, saving-investment (plus an auxiliary account to allocate investments), enterprises, government and rest of the world.

3. Scenarios

In order to analyse the effects of changes in fiscal instruments coherent with critical policy issues, we simulate three scenarios, i.e., changes in VAT, input tax, and income tax.

The first scenario considers the current exemption of VAT on food in Senegal. This later benefits the most to urban consumers to the detriment of producers which constitute the major part of poverty (AfDB/ADF, 2010). In view of the objective to strengthen the means of livelihood, educational and productive capacities, and food and nutrition security, it is worth making a link with the reinforcement of the family safety grants (*bourse de sécurité familiale*). The Senegalese government decided to support in 2017 about 300,000 vulnerable households with 100,000 XOF/year, for a total amount of 30 billion XOF.² In 2014 approximately 11.8 billion XOF have been spent for family safety grants (EU, 2015). As a result, set of scenario 1 is defined as below.

- Scenario (1a): taxation of 18 % VAT on all goods.
- Scenario (1b): taxation of 18 % VAT on all agricultural products and enhancement of family safety grants (i.e. increase in social transfers to the poorest households of 30 billion XOF using the allocation key of the poverty monitoring survey in Senegal presented in Figure 1). Note that in Dakar (distribution according to poverty quintile) it is assumed that only the three poorest quintile receive social transfers.
- Scenario (1c): taxation of 18 % VAT on all agricultural products.
- Scenario (1d): taxation of 18 % VAT on all agricultural products and enhancement of security grants family as in scenario 1.b.

Figure 1. Incidence of observed poverty by region (2011,%)

Source: Enquête de Suivi de la Pauvreté au Sénégal (ESPS_II), ANSD, 2011

The second scenario focuses on the need for developing the fertiliser sector, especially to improve the trade balance, to generate a spill-over effect on the rest of the economy (industry, infrastructure, fiscal resources) and also to increase agricultural yields and contribute to the economic and social development, see PSE and PRACAS (République du Sénégal, 2014a, 2014b).

In 2014, the input subsidies represent approximately 21 billion XOF (0.24 % of GDP), while in 2015 they decline to 8 billion XOF (0.10 % of GDP). Input subsidies include (i) subsidies to inputs (seeds, fertilisers, and plant protection products), (ii) subsidies for farmers (Dakar), and (iii) fuel subsidies to fishermen (EU, 2015). Note that the overall amount of the grant for seeds is 10.5 billion XOF during the 2013-2014 marketing year coinciding with the implementation of PRACAS (IPAR, 2015). In the 2013-2014 marketing year, the total amount of subsidy to fertilisers is 13.9 billion XOF. As a result, set of scenario 2 is defined as below.

² <u>http://www.dakaractu.com/20-milliards-alloues-aux-bourses-de-securite-familiale-en-2015-PM_a91063.html</u>

- Scenario (2a): Taxation of 18 % on all inputs (intermediate input). It should be noted that the chemicals is viewed as a factor of production (parameter).
- Scenario (2b): Taxation of 18 % on all inputs (intermediate input) with higher social transfers (see scenario 1b).
- Scenario (2b): Taxation of 18 % on all inputs (intermediate input) with the exception of fertilisers.
- Scenario (2d): Taxation of 18 % on all inputs (intermediate input) with the exception of fertilisers with higher social transfers (see scenario 1b).

The third scenario explores the development of income taxes. The agricultural sector contributes little to the tax revenue of Senegal. Therefore this sector appears as a target for the mobilisation of revenue. Agricultural productivity and income being generally low, it is not obvious that direct taxing this sector would be appropriate (in particular if measures discourage the modernisation and expansion of crops with higher added value). It seems preferable to tax indirectly the sector, according to the ability to pay of taxpayer. In practice, it would require to focus on income taxes paid by all with few exemptions and with thresholds that would properly affect land owners and wealthy farmers (IMF, 2017). As a result, set of scenario 3 is defined as below.

- Scenario (3a): Uniform taxation (increase of 50 % for all economic actors, including households).
- Scenario (3b): Progressive taxation (increase of 50 % for all economic actors, including households) with the exception of the poorest.
- Scenario (3c): Progressive taxation with higher social transfers (see scenario 1b).
- Scenario (3d): Redistribution of half of total social transfers in favour of the poorest.

Figure 5. Welfare by scenarios (2015, 2035, XOF billion change)

5. Conclusion

This paper provides a quantitative assessment of three set of changes in fiscal policy in Senegal. These scenarios are not realistic and should be refined in order to provide any policy recommendation. To evaluate such fiscal policy options, we propose two methodological enhancements. First, we use a CGE model that fits key developing country specificities for example the own supply of food by semi-subsistence households and their multiple commodity production activities (through the Home Production for Home Consumption module and the multiple-output structure of STAGE-DEV model, respectively).

Second, we calibrate the CGE model to an original disaggregated 2014 SAM for Senegal. This later 2014 consists of 209 accounts: 54 activities (14 of them accounts of households as producers) producing 53 marketed and 9 HPHC commodities using 3 types of labour (skilled, unskilled and semi-skilled) in 15 regions (45 labour accounts in total), 4 types of capital (agricultural, non-agricultural, land and livestock), 5 types of taxes (direct, indirect, sales, factors and imports), 33 regionalized RHG and one account each for margins, saving-investment (plus an auxiliary account to allocate investments), enterprises, government and rest of the world.

Scenarios on VAT, input tax, and income tax, are performed autonomously and their features are rather different. In order to better understand the drivers of results, additional researches are needed. Furthermore, future investigation shall entail additional tax instruments, such as land taxation. Also future modelling improvement shall better tackle the issue of nutrition, particularly through the development of a module for STAGE-DEV model able to analyse changes in calorie and micronutrient intake. Linking the CGE model with micro analysis techniques such as microsimulations has in the nutrition area a promising field of development as it might help in analysing policy impacts at both representative and single household level.

Figure A1. Agriculture as a percentage of GDP and level of taxation as a percentage of GDP (2014,%)

Note: This indicator agriculture as % of GDP includes forestry, hunting, and fishing, as well as cultivation of crops and livestock production. The LAC average includes developing Latin American and Caribbean countries only. Source: African Economic Outlook 2015; World Bank data (OECD/ATAF/AUC, 2016).
