Increase in Variable Costs per Acre
of Producing Wheat, Feed Grains,
Soybeans and Cotton in Selected Areas

By

W. H. Brown
Economic Research Service
United States Department of Agriculture

October 1974

This is an informal report of research progress re-
produced in this form for checking statistics and
statements for accuracy and for exposing research
while still in progress. Not to be quoted or cited.

INCREASE IN VARIABLE COSTS PER ACRE OF PRODUCING WHEAT, FEED GRAINS,
SOYBEANS AND COTTON IN SELECTED AREAS

W. H. Brown

Costs of crop production have risen rapidly since the Farm Production Economics Division published its reports on variable costs for 1970. Nearly all of the per acre cost increase is due to the rapid rise in prices paid for farm production items. The rate of use has changed only moderately for most inputs.

The 1970 estimates are being revised and the procedure for updating budgets is being computerized under the new firm enterprise data system project. But this will not be completed for some time. The purpose of this report is to provide interim estimates of cost changes since 1970 for feed grains, wheat, soybeans and cotton in selected producing areas.

These estimates are being made available for use of ERS commodity and policy analysts in projecting changes in production and the combination of crops that may be expected from the large changes in recent years in both prices and costs.

Except for the Great Plains, estimates of changes in variable costs per acre were obtained by adjusting the 1970 data for changes in prices paid as reported in Agricultural Prices, or ERS projections of prices paid (table 1). In the Great Plains a similar procedure was used except that revised estimates for 1973 were used as the bench mark for estimating other years. Because most of the increase in fertilizer prices occurred after the winter wheat crop was planted in the fall of 1973 estimates of winter wheat costs for the 1974 crop do not reflect the full impact of recent increases in prices paid. For this reason

projections were made for the 1975 winter wheat crop using the most recent information available.

Fertilizer used per acre on corn, wheat, cotton and soybeans, was updated with the use of SRS reports. Adjustments in quantities of fertilizer used per acre as well as the trend in yield per planted acre are shown at the bottom of each table. Adjustments in fertilizer quantities were most significant for wheat. Small adjustments were made for shifts to reduced tillage but the effect of this adjustment on total variable costs was small.

Estimates of variable costs are shown both including and excluding operator labor (table 2). Labor was divided between operator and hired labor in the same ratio as the figures for state employment reported in Farm Labor.

Variable cash costs for producing spring wheat (other than durum) approximately doubled from 1970 to 1974. Winter wheat variable cash costs for the 1975 crop will be at least double 1970 costs. The largest percentage increase occurred in areas where fertilizer accounted for a relatively high proportion of variable costs such as the eastern part of the Great Plains.

Costs for corn production increased about three-fourths over 1970 with the increase for irrigated corn in Nebraska being greater than costs shown for nonirrigated corn. Costs for production of grain sorghum, barley and oats increased by 82 to 90 percent from 1970.

Soybean variable cash costs increased about two-thirds from 1970 to 1974. The relatively large increase in soybean costs from 1970 to 1973--34 to 41 percent--was largely due to higher prices paid for purchased seed. The small increase from 1973 to 1974 in soybean costs

relative to other crops largely reflects the small amount of fertilizer used on soybeans and the small increase in prices paid for seed.

The smallest percentage increases but generally the largest dollar increases from 1970 to 1974 occurred on cotton. Although substantial quantities of fertilizer are used in most areas, fertilizer costs were a smaller proportion of total variable cash costs of growing cotton than for feed grain and wheat on the same farms.

The large increase in prices paid for input items not only resulted in a substantial increase in farm operating expenses but affected the competitive position of alternative crops in some areas. The per acre cost increase in Northern Indiana was only slightly higher for corn than for soybeans between 1970 and 1973. However, with the recent sharp rise in fertilizer prices the increase for corn is more than double the increase for soybeans from 1970 to 1974 (Table 4). Based on 1973 corn prices received by farmers and 1973-74 expected crop yields the break-even soybean-corn price ratio was reduced from 3.4 to 3.2 by the change in costs per acre from 1973 to 1974. However, this change in cost relationships was not sufficient to significantly affect supply response in 1974.

In the Coastal Plain of South Carolina and Georgia variable costs for corn increased more than for soybeans from 1970 to 1974 but the shift was not as great in Northern Indiana. This was largely because more fertilizer is used on soybeans in the Southeast than in the Cornbelt.

In both the Delta and the Coastal Plain of South Carolina and Georgia the increase in variable costs per acre of cotton from 1970

to 1973 and from 1970 to 1974 was from 3 to 4 times the increase in variable costs for alternative crops such as corn and soybeans. This shift in cost relationships was equivalent to a reduction of 5.5 to 8.0 cents in the price of cotton lint. The effect of relative changes in cost per acre of these magnitudes on acreage response depends on prices received for cotton and competing crops. In the southeast, in particular, expected prices received for the coming year could be such that returns above variable costs for cotton are relatively close to returns for corn and soybeans and the increase in costs per acre could have a substantial effect on acreage response.

The increase in variable costs for wheat from 1970 to 1973 and from 1970 to 1974 were about the same as the increase for grain sorghum, barley or oats in the same areas.

Prices paid for many production items have increased sharply since the passage of the 1973 Agricultural and Consumer Protection Act in August 1973. Under present legislation the target prices will not be changed for 1975. In addition the increase in prices paid between the time of passage of the Act and January 1, 1975 will not be taken into account in adjusting the target prices for 1976 and 1977. In view of recent bills introduced in Congress to modify the procedure to adjusting target prices, an analysis could be made of the effect of including the increase in prices paid between passage of the 1973 act and January 1, 1975 in the formula for adjusting target prices on these prices for 1975 and later years. However, because taxes and prices paid for some overhead items have not increased as much as inputs used directly on crops the percentage changes shown here are not appropriate for use in adjusting target prices.
