Rural Family Living

A color film strip that includes all the charts in this book can be purchased for \$4.00 from the address given below. The film strip is so designed that the charts can be cut apart and mounted as separate 2- by 2-inch slides.

An interpretation of the charts is given in the text of this chart book, a copy of which will be sent to every person ordering a film strip. One copy of the film strip and the chart book is being sent to the Extension Editor in each of the 48 States and Territories.

IMPORTANT

When Ordering Film Strips:

Send order and remittance (\$4.00) to Photo-Lab., Inc.,
3825 Georgia Avenue, N. W., Washington 11, D. C.

Do not send order to Bureau of Human Nutrition and
Home Economics.

The annual chart book of the Bureau of Agricultural Economics contains charts on the agricultural outlook. Charts covering the outlook for foreign markets are available in a separate publication of the Office of Foreign Agricultural Relations.

CHANGES IN CENSUS DEFINITIONS, 1940 AND 1950	76

POPULATION

In 1950, there were 39 million families in the United States. Only 6 million of these lived on farms (chart 1).

A larger share of the Nation's children than of its families continued to be supported by farms. Only 15 percent of the families in the United States lived on farms in 1950, but they were rearing 20 percent of the children.

Farm children were more likely to be members of large families than were urban children. Nearly half of the farm children under 18 years old were in families with four or more children while only one-fourth of the nonfarm children were in families that large. On the other hand, only 12 percent of the farm children, but 21 percent of the nonfarm children, were in one-child families in 1950.

Urban population increased 19 percent in the decade from 1940 to 1950, while rural population (farm and nonfarm) increased only 7 percent. Interesting regional developments occurred in this period. All four of the major regions in the United States increased in both their rural and urban populations except the South, which lost slightly in rural population (chart 2). The data on urban and rural residence are shown in accordance with the urban definition used in the 1940 Census of Population. (See note on change in Census residence definitions, p. 76.)

The West showed the greatest growth in urban population of any region, with an increase of 41 percent during the decade. Many factors combined to bring about such a spectacular urban increase. The long-time trend of shift in population from East to West continued. The rates

of increase in the population of the Pacific Coast States had been particularly high during recent decades and were given additional impetus by the development of industry during World War II. The gains made during the war were not lost with demobilization. Instead the westward movement continued.

The West also showed the greatest regional gain in rural population during this period, with an increase of 38 percent. One factor accounting for such an increase was the movement of people from congested urban areas into outlying rural nonfarm areas, a trend also observable in other parts of the country. This growth meant increasing demand for goods and services in rural areas and further population growth. Likewise, local demands for agricultural products arising from the increased urban population contributed somewhat to the rural expansion.

After the West, the South reflected the greatest urban development for the decade, with an increase of 35 percent. Although an industrial development was apparent throughout the South, the greatest urban expansion occurred in the TVA area and in the West South Central States, particularly in Texas.

The South was still the most rural region in the United States. The rural South, however, in sharp contrast to the urban South, failed to

gain population. Rather, it reported a 0.2-percent loss of population (about 50,000 persons) which, although small, was nevertheless a reversal of the general trend elsewhere to gain population over the decade. The beginning of the decade had seen an underemployment of labor in this highly rural area. The decrease by the end of the decade in rural population in the South, though small, may well reflect a partial adjustment to the 1940 overpopulation of the area in relation to its agricultural resources.

The Northeast in 1950, as in previous decades, had a larger urban population than any other region, accounting for approximately one-third of the urban population in the United States. Its urban rate of growth, however, was only 7 percent during the decade, markedly lower than that of the South or West.

The rural Northeast increased in population about 17 percent in the decade. For the most part, this was a residence phenomenon, reflecting the increase in commuters and "gentlemen" farmers in this highly industrialized region rather than a change in the commercial agriculture of the area.

The North Central region increased 15 percent in urban population, but only 4 percent in rural during the decade. Those States in and near the Missouri Valley Basin lost rural population.

During World War II the birth rate rose sharply, following the increase in incomes and the trend toward younger marriages of these years. The birth rate continued at its peak for the second half of the decade along with continued high incomes. As a result, the period between 1940 and 1950 saw a 55-percent increase in the number of children under 5 years of age and a 24-percent increase in the number of children from 5 to 9 years (chart 3).

Such an increase in the size of these two age groups demands serious consideration in the light of the rapid expansion in the services and facilities that must be made by communities throughout the Nation. School facilities are already being sorely taxed and will be more so. Other community facilities must likewise be prepared to bear the brunt of these "bumper crops" of youth for the next decade and beyond.

This dramatic increase in the birth rate was a reversal of a long-time trend. Our schools and other community facilities had been geared to the unusually small groups of children born in the 1930's. The severe depression of the early 1930's and the relatively low income level throughout the remainder of the decade contributed to the extremely low birth rate in this period. Between 1940 and 1950, the number of children 10 to 14 years old decreased by 3

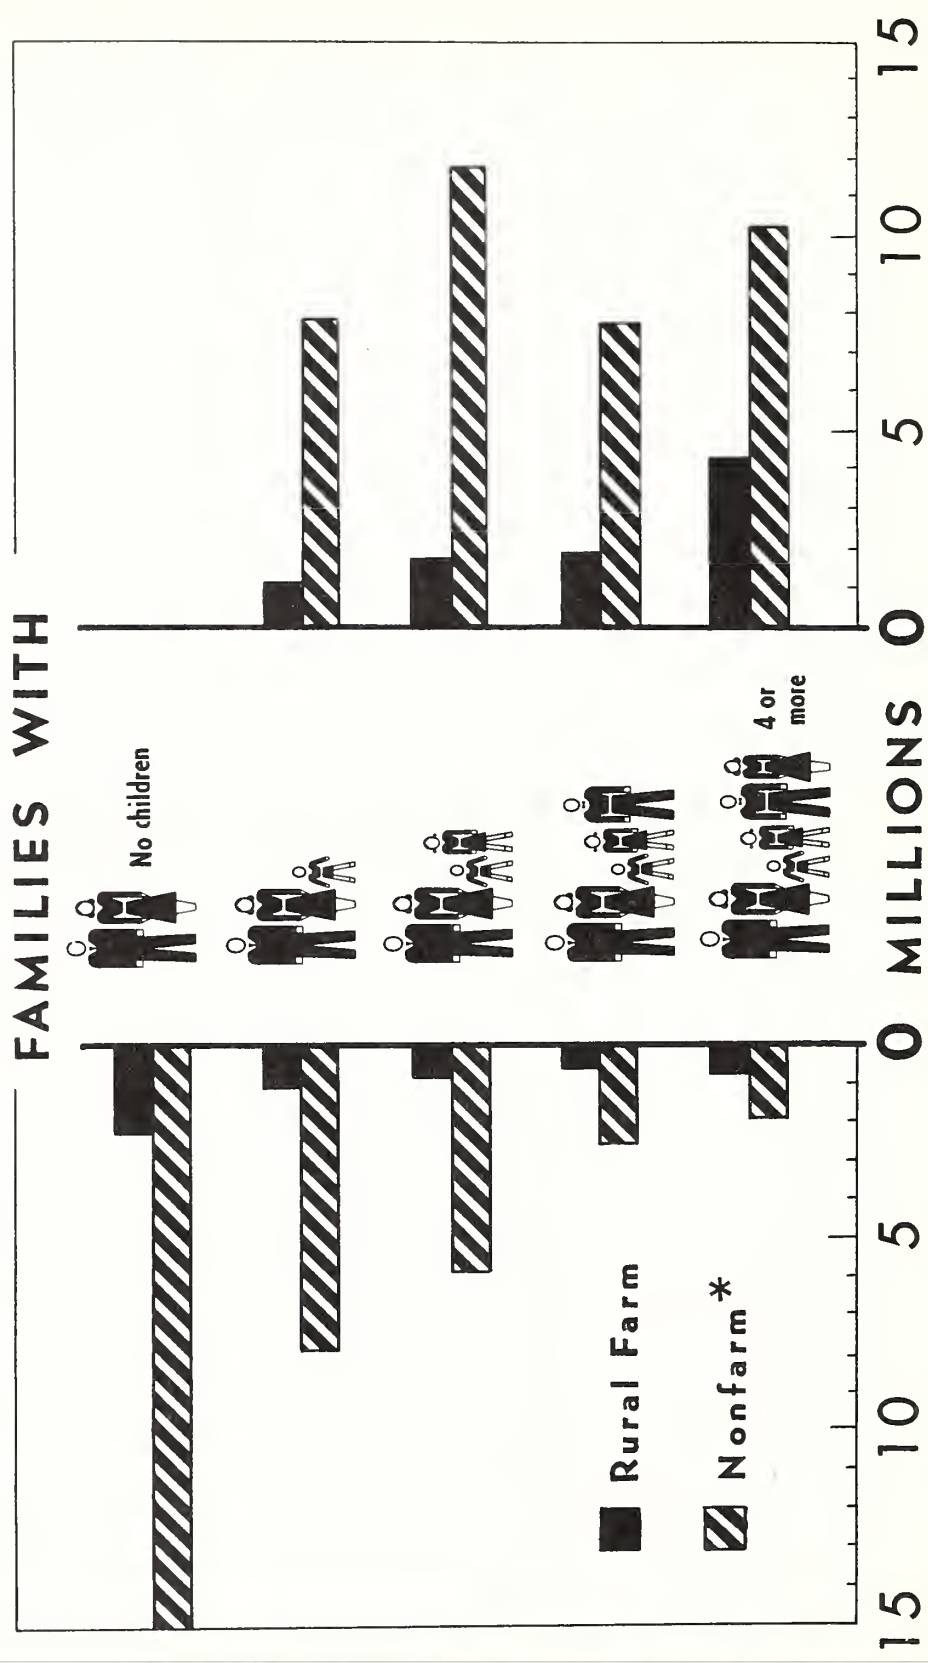

percent and the children 15 to 19, who were born in the depression years, decreased by 13 percent.

The decade that produced such startling increases in the number of young children also showed large increases in the number of older people. Between 1940 and 1950, people 75 years and over increased by 45 percent and those 65 to 74 years old increased by 33 percent.

That we have more and more older people in our population is a reflection of a long-time trend which has developed particularly during the past few decades. Advances in science, especially those contributing to health and medicine, have resulted in a steady decline in mortality rates over the years. In addition, the number of older people substantially increased between 1940 and 1950 because of the high birth rates during the period from 1865 to 1885.

As in the case of our very young, community facilities and services must be expanded to meet the needs of older people. Perhaps an even greater problem exists here in that it is a new problem, one that has not been part of the picture before. In a country that has always been "youth minded" an awareness of the problem is needed before progress can be made by communities in providing facilities to fit the needs of our older people.

INCOME

In 1951, farm operators' realized net income from agriculture is expected to be considerably above the 1950 level, although it is not likely to be as high as the record net farm income of 1947 (chart 4).

While not all farm families share equally in increased net income from agriculture, it is likely that far fewer farm families will have a family income under \$1,000 in 1951 than in the previous 3 years. Chart 5 shows the distribution of farm families by their net money income for 1947 and 1949. In 1947, when net income from agriculture was high, 25 percent of the families had an income under \$1,000, whereas in 1949 when net income from agriculture was about one-fifth lower than in 1947, about 34 percent of the farm families had an income under \$1,000. At the other end of the income distribution, 9 percent of the farm families had an income over \$6,000 in the peak year of 1947, while in 1949 only 5 percent did (table, p. 15).

The median farm family income in 1949 was considerably lower than the urban. Even if an allowance for home-produced food, fuel, and rental value of dwellings were added to the money income of rural families, it is likely that farm family incomes still would be lower. The median net money income of farm families in 1949 was under \$1,600; the median for rural nonfarm was a little under \$3,000; and for urban, about \$3,500.

The median farm family income figures include income from off-farm employment and other nonfarm sources. Such nonfarm income increased markedly during World War II for farm families, with additional increases in the postwar years. One factor accounting for the rise in nonfarm income of farm families is the increased employment in recent years of wives and family members other than the farm operator. In 1949, for example, 36 percent of the farm families had more than one earner, and 43 percent of the urban families had more than one (chart 6).

The median money income of farm families is considerably lower than that of urban families with the same number of earners (chart 7). This difference is much more important in explaining the over-all farm-urban income differences than is the difference in the proportions of farm and urban families with several earners.

Although family income increases as more earners contribute, it does not increase proportionately. The median net money income of farm families with two earners was approximately \$1,800 in 1949, while that for farm families with only one earner was \$1,400. The second earner in many cases is a part-time or part-year worker. The second earner often is the wife.

Employment of married women was given considerable impetus by the acute labor shortage that developed during the war. With demobiliza-

tion, many of these women continued to work, particularly as they were faced with the lessening value of the dollar and continued job opportunities. In March 1950, more than 15 percent of the farm wives were employed or seeking employment (chart 8). Many of them were working without pay on the family farm. Even more nonfarm women were in the labor force. Twenty-two percent of the rural nonfarm wives living with their husbands and 26 percent of the urban wives were either employed or looking for work in March 1950.

One of the most important factors determining whether married women work is the age of their children. Thirty percent of the married women who had no children under 18 were working in March 1950, while only 12 percent of those with pre-school age children were in the labor force at that time (chart 8). Of all the women who had no children under 6, but who had children of school age, 28 percent were working.

Another trend which received considerable impetus during World War II has been the increasing employment of older women. Twenty-seven percent of the women who were between 35 and 54 years of age were employed or seeking employment in March 1940 (chart 9). By 1944, this proportion had increased to 38. In 1950 it was even higher. Of the women 55 years and over, 13 percent were in the labor force in March 1940, while 19 percent were so occupied in March 1950.

Many young women, on the other hand, left the labor force after the war was over. Forty

percent of the women in the 20-to-34 age group were working in 1940. Four years later, at the peak of the war period, 44 percent were working. But with demobilization and the return of husbands to many family circles, the number of young women working decreased until by 1950 only 38 percent of those 20 to 34 years old were employed or seeking employment.

A study made in Illinois shows the kinds of occupations of employed farm women in 1946 in that State. Of the women members of the Illinois farm-operator families who were either working off the home farm or were self-employed, 20 percent worked as farm operators, 18 percent as clerks or saleswomen, and 14 percent as teachers; 14 percent earned money with household crafts, and 12 percent were employed in factories (chart 10). The occupation distribution in other areas may vary from this, depending upon work opportunities. These data were limited to farm-operator families and excluded financially independent daughters, thus increasing the relative importance of farm operators among the employed farm women.

Ten percent of the Illinois farm-operator families had women earners in 1946 (table, p.25). The greater proportion of these women were in families with relatively low income. In only 5 percent of those families with an income from \$5,000 to \$7,500 women were contributing money to the family income, while in 15 percent of the families with an income from \$1,000 to \$2,000 women were contributing.

1/ Women reporting earnings from multiple sources were classified by major source of earnings except that all women reporting any income from farm operations were classified as farm operators.

2/ Detail does not add to total because of rounding.

3/ Postmistress, operator of antique shop, cadet nurse.

4/ 16 years and over.

5/ The sum of net farm income, net earnings from employment, net income from nonfarm business, crafts, and roomers and boarders, and other cash income such as rents, interest and dividends, veterans' payments, less State and Federal income tax.

6/ Includes families with negative income and those with unknown income, not shown separately.

PRICES

Prices of goods and services used for family living began to advance sharply after the outbreak of hostilities in Korea in late June 1950. The pressure of an expanded defense program, aggravated by a wave of "scare buying" by both consumers and business, caused prices to rise much more rapidly than they had declined during 1949 and early 1950.

Prices of consumer goods had risen steadily throughout World War II and the early postwar years, reaching a peak in the summer of 1948. From then, they gradually declined until early 1950. Even at this "low" point, they were, on the average, more than a third higher than at the end of World War II. In the first 3 months of Korean hostilities, the price level regained the 1948 peak, and thereafter continued to rise. By June 1951, prices were approximately 5 to 10 percent above their previous all-time high.

Since February of this year the rate of price increase has diminished appreciably. Several factors may have contributed to this leveling off of consumer prices. On January 26, 1951, the General Ceiling Price Regulation became effective. This has been followed by additional orders and regulations designed to halt the upward spiral of prices and wages. Moreover, stocks of goods held by both retailers and consumers have increased during the past year. The index of department store stocks (adjusted for seasonal variation) in June 1951 was more than one-fourth higher than a year earlier. Many families are well-stocked with durable and semidurable goods as a result of heavy consumer buying in the summer of 1950 and the winter months of 1950-51. Retail sales of both durable goods, such as furniture and household appliances, and nondurable goods, such as clothing, were unusually high during the past year.

Not all prices advanced equally or at the same rate. The course of prices of the major categories of consumer goods and services can be traced by using the Bureau of Agricultural Economics Index of Prices Paid by Farmers for Commodities Used for Family Living (chart 11) and the Bureau of Labor Statistics Consumers' Price Index (chart 12). Both of these indexes have been revised since January 1950 in order to make them more accurate measures of price movements affecting families.

Increases in prices paid by farmers during the year from June 1950 to June 1951, were greatest for food (and tobacco), household furnishings, and building materials, each of which rose 13 percent. The BAE index showed that clothing increased 12 percent during the same period, while autos and auto supplies and household operations advanced 6 and 7 percent. In June 1951, prices of food and building materials were each 8 percent above their previous highs.

The Consumers' Price Index for moderate-income families living in large cities followed a pattern similar to the Index of Prices Paid by Farmers. By June 1951, the "all items" index was 9 percent higher than the June 1950 level, and 6 percent above the 1948 peak. The rent index increased 4 percent in the same period.

Beginning in March 1951, only fractional month-to-month price changes have occurred. It is important to realize, however, that this plateau is on a higher level than any previous price peak, which means that families are paying more for the goods and services they use than at any other time in our history. While there has been some weakening in recent months in wholesale prices of a few items--for instance, textile products--which may be reflected in retail prices, there is no indication that a general price decline is in prospect.

RURAL FAMILY CONSUMPTION

Spending in 1950 for all items of family living except housing and automobiles by accounting farm families in three North Central States remained approximately at the 1949 level, which was about 15 index points below the postwar peak of 1948 (table, p. 57). The aggregate spending of all U. S. consumers for these items, on the other hand, increased in 1950, passing by one point the 1948 peak.

Information on current expenditures of rural families, the extent to which they have built up inventories of durable and semidurable goods over the years, their home-production activities, health, and community facilities, all contribute to a picture of current rural family living. Available material on these aspects of rural family consumption are shown in the following sections on food, housing, housefurnishings and equipment, clothing, and health.

Food

Food supplies continue to be abundant and varied enough if shared equitably, to provide for the nutritional needs of everyone in the United States. The downward movement of the supplies of major nutrients available for consumption from the peak year of 1946 through 1949

was reversed in 1950, and continues upward in 1951 (chart 13). The slight rise in calcium and riboflavin indicated for 1951 will result from a higher consumption of fluid milk, cream, and ice cream. Increases in thiamine and niacin are associated with larger supplies of pork and poultry. The greater consumption of citrus fruit in 1951 than last year is reflected in an increase in the ascorbic acid content of the average diet.

An important factor in the nutritive value of our food supply is the enrichment of flour and bread with iron, niacin, thiamine, and riboflavin. Enrichment has improved the quality of the diet of both rich and poor, but the lower income groups have benefited more than the higher income groups because of the more important part grain products play in their diets (chart 14). Among city families in the spring of 1948, enrichment increased the iron in the diets of families with \$1,000 to \$2,000 income by 14 percent and the niacin by 15 percent (table, p. 37). In the diets of families with \$5,000 to \$7,000 income, it increased the iron by 10 percent and niacin by 9 percent. The greatest contribution was in thiamine, with increases of 20 percent in the lower and 13 percent in the higher income group. The increase in riboflavin was proportionately smaller because so large a part of the total comes from milk.

Farm family expenditures for food have been increasing rapidly in recent years (chart 22). In the late 1930's and just before World War II, the change in per capita spending of the accounting farm families in three North Central States followed closely that of all U. S. consumers. During the war, the increase was less rapid, which is partly explained by the increased use of home-produced meat by farm families during that period. Following the war, both the account-keeping farm families and all U. S. consumers had sharply increasing expenditures for food, but the increases by these farm families were greater than those for all U. S. consumers. This is related in part to increased farm income, to changes in the types of food bought by farm families, to transfer of processing out of the farm home, and possibly to a decrease in home production of food.

Although in some respects farm diets are becoming more like city diets in the same area, there are still important differences. Farm families in two counties of Minnesota consumed larger quantities of fats, sugar and sweets, and grain products than their city neighbors in nearby Minneapolis-St. Paul (table, p. 39). The greater energy expenditure for farm activities may account for this difference. The farm families also used more milk and eggs and slightly more meat, poultry, and fish (chart 15). The fact that a large part of these foods was

home-produced was probably a factor; families are likely to eat larger quantities of the foods they produce and have on hand than those they have to buy. The city families, on the other hand, were eating more fruits and vegetables than the farm families. This may have been due to the fact that the study was made in a spring week when farm gardens were producing little and the previous year's canned or stored supplies were running low.

In Birmingham, Alabama, and Minneapolis-St. Paul, Minnesota, city families with gardens used more pounds of fruit and vegetables during a summer week than did those without a garden (chart 16). In the southern city, about the same quantities were purchased by both groups, but families with gardens consumed about a fifth more than those without gardens. In Minneapolis-St. Paul, families with gardens purchased less than those without, but total consumption was greater.

Many studies have shown that families who raise much of their own food supply have better diets than those who buy most of their food. Also, to the extent that home-produced food is substituted for purchased food of the same kind, it releases money for other kinds of food or for other uses. These are some of the reasons for the renewed emphasis on gardening and home food preservation in 1951.

1/ Families with any home-produced vegetables during the survey week were counted as having a garden. If a family had a garden but no home-grown vegetables during the week, it was counted in the "no garden" group.

2/ 30 families with gardens, average household size 2.60 persons; 129 families without a garden, average household size 2.55 persons.

3/ All vegetables and fruits, except potatoes, sweetpotatoes, dry beans and peas, and citrus fruit.

4/ Base in each city is amount from all sources consumed by families with a garden.

5/ 39 families with gardens, average household size 2.38 persons; 108 families without a garden, average household size 2.28 persons.

6/ 0.05 pound or less.

7/ 0.05 percent or less.

Housing

Data from the 1950 Census provide a benchmark as to the present status of farm housing in comparison with rural nonfarm and urban housing. Electrification has spread rapidly in the past decade. About 80 percent of the dwelling units in the United States had electric lights in 1940, but by 1950 nearly 95 percent had them. Nearly all of the families without electric lights were rural. More than 20 percent of the farmhouses and 10 percent of the rural nonfarm houses were still without electric lights in 1950 (chart 17).

Considerable progress has been made also in the installation of running water and flush toilets in dwellings in this decade, although the increase has been a little less rapid than in electrification. The proportion of houses for the country as a whole with running water increased from 70 to 82, and the proportion with flush toilets increased from 65 to 75 from 1940 to 1950.

Farmhouses continue to have plumbing less frequently than rural nonfarm houses, and those

in turn, less than the urban. Running water in farm dwellings is about half as common as is electric lighting. Flush toilets were found less frequently than running water; only about 30 percent of the farm families had flush toilets in 1950, whereas a little more than 40 percent had running water. Since electricity is usually a forerunner of the installation of running water and a sewage disposal system, more progress will probably be made along these lines in the coming decade.

In spite of the fact that a larger proportion of the farm dwellings are owner-occupied than are urban dwellings, the condition of farm dwellings in 1950 was poorer (table, p. 45). Rural houses were more crowded than urban, and rural farm more than rural nonfarm. Furthermore, 21 percent of the farmhouses were classed as dilapidated by Census enumerators, who were given special instructions to try to make this a meaningful valuation. Only 6 percent of the urban dwellings were classed as dilapidated.

Storage facilities such as closets, attic, or basement, are important construction features making for a more livable house and more efficient home management. A study of farm housing in seven southern States in 1948 and 1949 showed that 20 percent of the houses on owner-operated farms had none of the following storage facilities: Closets, basement, attic, pantry, or storeroom (chart 18). A desirable standard for space for clothing storage is one clothes closet for each bedroom, yet more than a third of the houses of the southern farm owner-operators had no clothes closet, and a fourth had only one.

The number of closets in southern farmhouses was not related to the age of the house. As many older houses had closets as did the newer ones. Rather, closets tend to be related to the socioeconomic status of the farm family as shown by a scale summarizing education, social participation, housing facilities such as running water and electricity, and durable goods owned by the family (table, p. 47).

Many farm families in the past few years have built new houses or have made major improve-

ments in their houses. The stage of the family life cycle in which farm families build new homes influences the kind of house plans that are chosen and often the financial plans made. Of the farm families that built houses from 1948 to 1950 in North Carolina, the largest proportion had children still at home (chart 19). About a fourth of the families that built had one or more young children, all under 10. Forty-two percent of the group building had one or more children 10 or over still at home. The older, childless families and those whose children were no longer at home made up only 11 percent of the group.

Relatively young families were building most of the farmhouses in North Carolina. About 45 percent of the farmers building a house were under 35 years old, whereas families of this age group were a far smaller proportion of all farm owner-operators in the State (table, p. 49). Veterans' loan benefits, bonuses, and training programs probably have meant that the proportion of the younger farm families building a house has been higher in recent years than before.

Housefurnishings and Household Equipment

Rural families made great improvement in their housing equipment during the years from 1940 to 1950, although farm women still do not have the household equipment to work with that urban women have. Relatively high farm income and the spread of electrification in rural areas have been important factors in the improvement. Most of the increase in farm household equipment took place in the last half of the decade as supplies of consumer goods increased following the war.

Mechanical refrigerators have been purchased in great numbers all over the country in recent years, with many purchases in rural areas. The proportion of families in the United States with a mechanical refrigerator has nearly doubled from 1940 to 1950 (from 44 to 80 percent). Today, 60 percent of the farm and 70 percent of the rural nonfarm families have one, as compared with nearly 90 percent of the urban (chart 20).

The proportion of families cooking with electricity or gas also increased markedly (from 54 percent in 1940 to 73 percent in 1950 for the country as a whole), although the increase was not as rapid as that for mechanical refrigerators in this period. The rural-urban differences in the proportion of families cooking with electricity or gas are even greater than for refrigerators. Only about a third of the farm families in 1950, but 85 percent of the urban families, had a gas or electric cook stove.

Radio ownership has ceased to be a distinguishing characteristic between farm, rural nonfarm, and urban families. In 1950, less than 5 percent of the families in the entire country lacked a radio. Television, however, has considerable rural-urban differences because it has necessarily developed most in areas of heavy population concentration. In 1950, there was a television set in 16 percent of the urban dwelling units, but in only 7 percent of the rural nonfarm and 3 percent of the farm dwellings.

Electricity in the farmhouse can be a marked impetus to modernizing household equipment when income is relatively high. This is shown by the equipment inventories of selected types of families in four Kansas counties in 1948-49 (chart 21). Nearly all of the families with electricity had a mechanical refrigerator and a self-heating iron, but only about half of those without electricity had them. Nearly three-fourths of the families with electricity had a vacuum cleaner, while the number of non-electric vacuum cleaners among the families without electricity was negligible.

Even without electricity, improvement in household equipment can be made when money is available. Among the farm-operator families surveyed in the four relatively high income Kansas counties, 89 percent of the families without electricity had a power-driven washing machine and 66 percent had a gas cook stove.

Expenditures for furniture and household equipment by farm families keeping accounts in three North Central States, were higher in 1950 than in 1949 (chart 22). Such expenditures,

along with food, were the only major categories of spending increased by these farm families in 1950. This followed a sharp cut in such spending in 1949 from the record spending in 1947 and 1948. The increase from 1949 to 1950 in the amount spent per person by these farm families for furniture and equipment was not as great as the increase in the amount spent per person by all U. S. consumers for such items.

A study made in Montana for the year 1949 indicates that about 40 percent of the \$300 average expenditure for housefurnishings and household equipment by all farm families was spent for major equipment such as stoves, refrigerators, and washing machines (chart 23). Regardless of the size of the farm business, families were spending a third or more for major equipment (table, p. 59). Only about 7 percent of the total furnishings and equipment money spent by farm families was for household textiles and another 7 percent for rugs and other floor coverings. Furniture took only 14 percent. The remainder was spent for small kitchen equipment and for miscellaneous items such as lamps, radios, baby equipment, tools, and repairs.

Electric sewing machine.....	28	3
Other sewing machine.....	61	90
Radio in use.....	94	83
Number of families in sample.....	391	70

^{1/} The families without electricity have a lower average income than do those with electricity. However, a similar table restricted to families with less than \$3,000 income reveals the same inventory relationship as shown here between all families with electricity and those without.

^{2/} Some families reported more than one cook stove. A few had both electric and gas; but because of rounding the unduplicated proportion having gas or electric cook stove is also 95 percent.

^{3/} A few families without electricity reported ownership of some electric appliances; reasons include buying in anticipation of electricity and previous occupancy of a house with electricity.

Clothing

Spending for clothing by the accounting families in three North Central States declined in 1950 for the second consecutive year. The same trend was evident in the spending of all U. S. consumers (chart 22).

Clothing inventories of farm families studied in two counties in Minnesota in 1950 indicate reasonably well stocked wardrobes (table, p. 63). The husbands in these families owned, on the average, about 2 outdoor jackets, 4 dress shirts, 2 sport shirts, 2 suits, 4 overalls or coveralls, 6 work shirts, 2 pairs of work trousers, 9 pairs of heavy socks, 7 pairs of socks for dress or general wear, and 3 pairs of shoes of all types. The wives in

these families owned 3 coats, 6 house dresses, 5 dresses of other types, 2 blouses, 1 skirt, 8 aprons, 7 pairs of long hosiery, 4 pairs of anklets, and 4 pairs of shoes for dress, work, or sport.

On the whole, the younger farm husbands owned more clothing than the older ones. For a few items, such as sport shirts and pull-over sweaters, the younger men had far more in their clothing inventories than the older men (chart 24). Only an occasional item, such as coat-style sweaters and overcoats or topcoats, was owned in larger numbers by the older husbands than by the younger, and there the difference was slight.

The same study indicates that home sewing is more prevalent among farm than city families (chart 25). However, even in farm families it is an important source of new garments for only a few types of clothing worn by women and girls; for the greater part of women's wardrobes, and for the wardrobes of the men and boys in these families, it is unimportant.

Slightly more than half of the farm wives added home-made aprons or smocks to their wardrobes during the year. For the entire group surveyed, such garments averaged 2 per person. The home-made articles, many of which were made of feed sacks, constituted about three-fourths of all aprons and smocks acquired during the year. Somewhat less than half of the farm wives reported home-made house dresses; the number of these garments averaged, for the group as a whole, a little over one per person.

In Minneapolis-St. Paul, both the proportion of wives reporting home-made aprons, smocks and house dresses and the proportion of total garments acquired that were home-made were markedly lower than for farm wives. Only about one-eighth of the city women reported such acquisitions, and only about a fourth of the garments were home-made.

Other home-made garments reported by a considerable number of farm wives were nightgowns and dresses for street and dress wear. About an eighth of the women had new home-made garments of these types during the year. Home-made nightgowns were reported by fewer city wives, and dresses by somewhat more city than farm wives. Other garments were reported as made at home by insignificant proportions of both farm and city wives.

Health

Health and medical care are in the spotlight as national problems. Some aspects of the problems are peculiarly acute for the farm population.

The dearth of physicians in rural areas has long been recognized. A comparison of the 1940 and 1949 ratios of physicians to population in counties of different degrees of rurality shows that the situation now is worse than before World War II (chart 26). For the nation as a whole and for the metropolitan service areas, there was a small decrease in the physician-population ratio, but the loss has been greatest in isolated counties (table, p. 69). In these isolated counties the ratio was 81 physicians per 100,000 population in 1940, but only 74 in 1949, a decrease of nearly 10 percent.

This decrease in the ratio of physicians to population in isolated counties was greatest in the South and Midwest, the regions of the greatest rural population. The loss was about 10 percent in these regions, and about 5 percent in the Northeast and West. The loss of

physicians from isolated counties in the South is particularly significant since the 1940 ratio of physicians to population was lower there than in counties of the same class in other regions.

In contrast to the picture of availability of medical care in rural and urban areas, a recent study in Michigan makes the point that there is more time lost because of illness in rural than in urban areas. Relatively more rural than urban people in Michigan lost a day or more from their work or other regular activities because of illness (chart 27). Furthermore, more rural people lost time because of extended illnesses than did urban groups.

Continued high spending for medical care, reported by account-keeping farm families in the Middle West, shows that farm people recognize its importance. Their expenditures for medical care have shown no appreciable decrease in the postwar period and have been maintained on a level approximately three times their prewar average (chart 22).

In the past two decades health insurance has come into increasing prominence as a method of solving some of the family's financial problems in regard to medical care. However, the benefits paid by various types of health insurance plans are still only a small portion of the total medical costs. Even though 50 percent of the population was covered by some type of health insurance in 1950, only 12 percent of the total medical bill that would otherwise have been met directly by consumers was paid through insurance benefits (chart 28). Most popular types of health insurance were hospital and surgical (21 percent) and hospital only (15 percent). Only 3 percent of the population had relatively comprehensive coverage.

Although exact information is lacking, it is known that the proportion of the population insured is much lower in rural than urban areas. The organization of health insurance plans is slower in rural areas because group insurance, which provides a sound actuarial basis for such plans, is easier to apply in urban centers or industrial groups.

Infant mortality statistics are often used as an over-all index of health level of the entire population as well as of the infant population. For that reason, data on

rural infant mortality rates (deaths per 1,000 live births) are presented here (chart 29).

The best and the worst infant mortality records are made in rural areas. In 1948, the most recent year for which rural-urban tabulations have been made, four States had rural infant mortality rates below 24.8, the lowest rate reported for urban areas by any State, and two States had rural rates above 62.0, the highest rate reported for urban areas by any State (table, p. 75).

The infant mortality rates in rural areas in about half of the States were under 30 deaths per 1,000 live births; in about a third, the rates were between 30 and 40. For urban areas, the rates under 30 were reported by about a third of the States, and rates between 30 and 40 by about half. This distribution of States suggests that the U.S. average infant mortality rate is lower for rural areas than for urban areas. This, however, is not true. The bulk of the urban population lives where the urban infant mortality rates are favorable, but the bulk of the rural population is in areas with the less favorable rural rates. This distribution of population results in an average rural rate that is a little higher than the average urban--33.1 as compared with 31.2.

^{1/} Metropolitan counties are counties within standard metropolitan areas as defined by Census. A greater metropolitan county is one containing any part of a standard metropolitan area of 1,000,000 population or more. Lesser metropolitan counties are all other metropolitan counties. Adjacent counties are counties that are not themselves metropolitan but are contiguous with metropolitan counties. All other counties are classified as isolated. Of these, semirural counties contain an incorporated place of 2,500 or more population; rural counties do not.

CHANGES IN CENSUS DEFINITIONS

1940 AND 1950

Data in the 1950 Census incorporate major changes in the classification of the population by urban, rural nonfarm, and rural farm residence. As a result, 1950 population data by residence are not comparable with corresponding data based on the 1940 and earlier censuses. In 1950, the urban definition was modified to include inhabitants of closely built-up suburban areas and other densely settled areas, most of which had been classified in earlier censuses as rural. The net effect of this change in definition was to transfer 7.5 million persons, or 5 percent of the total population, from the rural to the urban classification, most of this at the expense of the rural nonfarm population.

The 1950 Census also incorporated changes in the method of determining farm and nonfarm residence. In 1950, persons living on "farms" who were paying cash rent for their house and yard only were classified as nonfarm; likewise, all persons in institutions, summer camps,

motels, etc., were classified as nonfarm. Previously, these could have been classified as farm. This change in definition resulted in a transfer of approximately 2.1 million persons from the farm to the nonfarm classification.

Data for 1940 cannot be adjusted to 1950 definitions because the arbitrary boundaries established by the 1950 Census do not follow the boundaries of enumeration areas of the 1940 Census. The 1950 data, however, can be classified by 1940 definitions to show rural and urban changes. Population data so classified are presented in chart 2.

The 1950 Census definition for family is a group of two or more persons related by blood, marriage, or adoption and residing together; all such persons are regarded as members of the same family. This represents a change from the definition used in the 1940 Census.
