### **ABSTRACT**

The present study attempts to assess the financial feasibility of layer farms of poultry birds in the Chittoor district of Andhra Pradesh, India. In total, 60 farms were considered for the study, with 20 each for small, medium and large size. A pretested questionnaire was used to collect data from poultry farmers. The Net Present Worth is highest for large farms followed by medium and small farms at both 12 and 16% discount rates, proving the economic viability of farms. The Benefit-Cost Ratio and farm size were positively related and the large farms were economically more viable. The internal rate of return is higher than that of the discount rate for all sizes of farms which implies that investment is feasible. Even though the returns are decreased by 10% (Case I) or costs increased by 10% (Case II), the small, medium and large poultry layer farms are economically feasible at both 12% and 16% discount rates as NPV is positive and BCR is greater than 1. But if the returns are decreased by 10% and Costs increased by 10% (Case III), the small farms become financially infeasible at both discount rates, whereas medium farms become financially infeasible at a 16% discount rate only. The large layer farms are economically feasible at both discount rates if the returns are decreased by 10% and Costs increased by 10% (Case III). Based on NPV, BCR and

\*Corresponding author: E-mail: [soumyaagrico@gmail.com](mailto:soumyaagrico@gmail.com);

IRR, large layer farms were most profitable followed by medium and small layer farms. The benefits per bird were highest and cost of production was lowest in case of large farms. The study revealed that poultry layer farming is a profitable business in Chittoor district.

**Keywords:** Poultry; layer farms; NPV; BCR; IRR.

## 1. INTRODUCTION

Poultry is one of the promising segments of the agricultural sector in India. Egg production is increasing at the fast pace of 8 per cent per annum, whereas crop production is increasing at a slow pace of 1.5 to 2 per cent per annum. The egg production in India is 75 billion in the year 2017. Out of which 75% of eggs are produced from organised farms and the remaining 25% produced from backyard poultry farming. Consumption of poultry products increased in India owing to changing food habits of people.

Andhra Pradesh is one of the promising states in India in promoting the Livestock Sector. The state stands first both in egg and meat production. The Egg Production in the State in the year 2017-18 is 17.78 billion. This constitutes 23.71% of the total egg production in the country (75 billion) i.e., every fifth egg produced in the country comes from Andhra Pradesh. Thus, the State can be called "EGG BASKET" of the country. The predominant egg producing districts in the state are East Godavari, West Godavari, Krishna, Guntur, Chittoor and Visakhapatnam districts. Nearly a million jobs are created by the poultry sector in Andhra Pradesh. The Poultry sector contributes approximately Rs.90,000 cr. to the GDP of India and about Rs.8217 cr. to the economy of Andhra Pradesh.

The Chittoor district has the largest number of poultries and hatcheries, and thousands of families depend on them. Chittoor is the fifth largest egg producing district in Andhra Pradesh. In the year 2017-18, 12770.63 lakhs of eggs are produced in this district. The present study is an attempt to assess the financial feasibility of layer farms of different sizes in this district.

## 2. LITERATURE REVIEW

Bharathi [1] while evaluating the profitability of poultry enterprise worked out the IRR as 29.67 per cent for small farms and 32.35 per cent for large farms, which is quite higher than existing bank interest rate. The benefit cost ratio was 1.06 and 1.15 on small and large farms

respectively. The net present value was positive both for small and large farms. All these indicators showed that poultry production is economically viable. The results further revealed that it would take about four years to recover the entire investment made on poultry farm on an average.

Mohsin et al. [2] attempted profitability analysis of broiler production in Rawalpindi district of Pakistan. They observed that on small broiler farms, BCR was less than one, and NPW was negative. They were 0.95 and Rs. -34718. On medium farms, the benefit-cost ratio (BCR) and net present worth (NPW) were 1.10 and Rs.9332, respectively. On large broiler farms, the BCR and NPW were 1.34 and Rs.78,094, respectively. This indicates that small broiler farms were in loss while medium and large farms were making profits. The results of marginal analysis showed that marginal rate of return (MRR) for small to medium farms was 169.20 per cent and for medium to large farms, 156.97 per cent. It means when we increase the broiler farm size from small to medium, the poultry farmer was expected to recover Rs.1.00 along with additional Rs.1.69. Similarly, when we shift farm size from medium to large, the broiler farmers expect to recover Rs.1.00 along with an additional Rs.1.56.

Ahmad et al. [3] studied economics of broiler production in Allahabad district, found that the Benefit-Cost ratio was 1.19, 1.20 and 1.30 for the broiler farms of small, medium and large sizes respectively. Net Present Value (NPV) calculated for small farms was Rs.23,324.95, medium size farms Rs.53,080.13 and large farms Rs.1,44,583.26. They concluded that large farms received higher profits as compared to medium and small farms.

Singh et al. [4] studying the worthiness of investment in broiler farming, measured the productivity of capital. They reported that net present value (NPV) was highest among large broiler farms (Rs.26,62,245) followed by medium (Rs.6,91,352) and small (Rs.1,76,126), showing an increasing trend with the increase in farm size. As the net present value was positive in all

farms, all the farms are financially feasible. Benefit-Cost Ratio (BCR) was 1.04, 1.08 and 1.12 for small, medium and large broiler farms. It increased with increase in farm size, and the large farms were economically more viable. The internal rate of return (IRR) was highest on large farms (33.32 per cent) followed by medium (29.07 per cent) and small (23.30 per cent) farms. Since IRR is greater than discount rate representing the opportunity cost of capital, farms of all three sizes are financially viable.

A project report for commercial layer farming of 5000 capacity [5] prepared by West Bengal Poultry Federation and NECC laid down that layer farm of 5000 birds is lucrative as indicated by IRR (48.05 per cent), B-C ratio (1.13) and NPV (Rs.19,82,943) worked out.

In a pre-feasibility study for 30,000 layers made by Small and Medium Enterprises Development Authority (SMEDA) [6], IRR, NPV and payback period were worked out. They were 45 per cent, Rs. 65,852,862 and 4.32 years respectively. These economic indicators amply established the profitability of layer farming. SMEDA conducted many such studies. The results of financial analysis vindicated the above finding.

Dinesh and Sharma [7] studied 100 poultry farms of layers in Namakkal district of Tamil Nadu to assess the financial feasibility of farms of various sizes. Based on the values of net present value, benefit-cost ratio and internal rate of return, layer farms of all size group layer farms are found to be financially viable and most profitable. While the Net Present Value of investments in small, medium and large farms at 15% discount rate were Rs. 1,94,926, Rs. 6,85,979 and Rs. 25,48,436 respectively. The benefit cost ratio was higher in large farms at 1.033 followed by medium (1.030) and small farms (1.019). The internal rate of return is highest for the large farm was 31.15 per cent whereas for small farms and medium farms were 22.89 per cent and 23.06 per cent, respectively.

### 3. METHODOLOGY

The study was conducted in Chittoor district of Andhra Pradesh. The layer farms are grouped into 3 categories based on number of birds, small ( $\leq 5000$  birds), medium (5001-20000 birds) and large ( $> 20001$  birds). 20 layer farms are selected from each of these groups i.e., in total 60 farms are considered for the study.

#### 3.1 Net Present Value

It is also sometimes referred as net present worth (NPW). It is the present worth of the incremental net benefits or incremental cash flow stream. Net present value (NPV) of a project is estimated using the following formula.

$$NPV = \sum_{j=1}^n \frac{B_j - C_j}{(1+i)^j} \quad (1)$$

Where

$B_j$  = Benefits in  $j^{\text{th}}$  year

$C_j$  = Costs in  $j^{\text{th}}$  year

$i$  = Discount rate

$n$  = Number of years

$j$  = 1 to  $n$  years

The net present value (NPV) should be positive to indicate that the project investment is economically viable.

#### 3.2 Benefit-Cost ratio (BCR)

It is the ratio of present value of costs and present value of benefits. For any project to be viable, Benefit-Cost ratio should be more than one. The project with highest Benefit-Cost ratio must be opted for implementation among the alternative projects. Benefit-Cost ratio is calculated using the following formula.

$$B - C \text{ ratio} = \frac{\sum_{j=1}^n \frac{B_j}{(1+i)^j}}{\sum_{j=1}^n \frac{C_j}{(1+i)^j}} \quad (2)$$

Where

$B_j$  = Benefits in rupees in  $j^{\text{th}}$  year

$C_j$  = Costs in rupees in  $j^{\text{th}}$  year

$i$  = Discount rate

$n$  = Number of years

In the present investigation, the net present value (NPV) and benefit-cost ratio (BCR) were calculated at 12 and 16 per cent discount rates.

#### 3.3 Internal Rate of Return (IRR)

It represents the average earning capacity of an investment over the economic life period of the project. It is the discount rate at which the present values of cash flows are just equal to zero i.e.,  $NPW = 0$ . In other words, the benefit-cost ratio calculated at IRR is unity. Mathematically, it can be represented as

$$IRR = \sum_{j=1}^n \frac{B_j - C_j}{(1+i)^j} - I \quad (3)$$

Where

$B_j$  = Benefits in rupees in  $j^{\text{th}}$  year

$C_j$  = Costs in rupees in  $j^{\text{th}}$  year

$i$  = Discount rate

$n$  = Number of years

$I$  = Initial investment

The internal rate of return (IRR) was calculated through interpolation technique by using different discount rates so as to see that the net present value is equated to zero. The lower and higher rates would be used to obtain positive and negative values of net present value respectively. Then the interpolation method indicated below was used to arrive at the IRR.

$$IRR = \text{Lower discount rate} + \left[ \frac{\text{Difference between 2 discount rates}}{\left[ \frac{\text{Present value of cash flows at lower discount rate}}{\text{Absolute difference between the present values of cash flows at two discount rates}} \right]} \right]$$

When the calculated IRR is greater than the market rate of interest, then the investment in the project is considered viable and worthy.

### 3.4 Sensitivity Analysis

Sensitivity analysis involves changing of one or more values in net present value (NPV) equation and recalculating the NPV [8]. This analysis provides better insight into the profitability of

investment. Under these three cases are considered

**Case I:** Returns decreased by 10 per cent

**Case II:** Costs increased by 10 per cent

**Case III:** Returns decreased by 10 per cent and Costs increased by 10 per cent simultaneously

## 4. RESULTS AND DISCUSSION

### 4.1 Economic Viability of Layer Farms

The results for economic viability of different sized layer farms are presented in Table. 1 and entire calculations presented in Appendix. The net present value of large farms at 12% discount rate is Rs. 3,22,61,595 whereas for medium and small farms is Rs. 70,85,828 and Rs. 22,42,560 respectively. The BCR for small, medium and large farms are 1.19, 1.23 and 1.27, respectively. The net present worth of small, medium and large layer farms at 16% discount rate are Rs.2,54,53,888. Rs.43,39,808 and Rs.17,15,595 respectively and the corresponding BC-ratios are 1.17, 1.22 and 1.25 respectively. The Net Present Worth is highest for large farms followed by medium and small farms at both discount rates. The net present values for all the farms are positive at both 12 and 16% discount rates which in turn prove the economic viability of farms. The Benefit-Cost Ratio was positively related with farm-size and the large farms were economically more viable. The IRR for highest for large (88.45%) farms followed by medium (73.93%) and small (59.42%) farms. The internal rate of return is higher than that of the discount rate for all sizes of farms which implies that investment is feasible. These results are in conformity with Dinesh and Sharma [5].

**Table 1. Economic viability of layer farms of different sizes**

Particulars	Discount rates (%)	
	12	16
<b>Small farms</b>

*Case I: Returns decreased by 10 per cent**Case II: Costs increased by 10 per cent**Case III: Returns decreased by 10 per cent and Costs increased by 10 per cent simultaneously*

## 4.2 Sensitivity Analysis

Table 2 presents the results of sensitivity analysis. The calculations are presented in Appendix.

### 4.2.1 Case I

When the returns were decreased by ten per cent, net present value (NPV) remained positive on all size groups of layer farms at 12 per cent discount rate. The benefit-cost ratio was more than one on all farms. The same trend was discernable even at 16 per cent discount rate. The internal rate of return (IRR) worked out to 31.58, 42.92 and 54.46 per cent on small, medium and large layer farms. This indicates that all the three size groups of layer farms are financially viable under this situation i.e., even when the net returns were decreased by 10 per cent.

### 4.2.2 Case II

When the costs were increased by 10 per cent, the net present value (NPV) was Rs.10,70,435 on small farms, Rs.31,62,513 on medium farms and Rs.2,02,41,964 on large farms at 12 per cent discount rate. The benefit-cost ratio was 1.08, 1.12 and 1.15 on small, medium and large farms respectively. At 16 per cent discount rate also, NPV was positive and B-C ratio, more than one on all size groups. The internal rate of return (IRR) was 34.01 per cent on small farms, 45.98 per cent on medium farms and 57.51 per cent on large farms. Hence, under this situation also, all the three size groups of layer farms are economically viable.

### 4.2.3 Case III

When the returns were decreased by 10 per cent and Costs increased by 10 per cent simultaneously, large and medium layer farms remained financially viable while small farms became non-viable at 12 per cent discount rate as evidenced by the indices of economic viability. The NPV on small farms became negative (Rs. - 3,25,946), BCR, less than one (0.97) and IRR less than discount rate of 12 per cent (4.53 per cent). At 16 per cent discount rate, small as well as medium layer farms became economically non- viable. Their NPV became negative, BCR less than one and IRR less than discount rate of 16 per cent. However, the large farms continued to be financially sound even under this situation. Their NPV was Rs.28,30,286, BCR, 1.03 and IRR, 24.34 per cent.

Thus, it may be concluded that investment in layer farming is financially viable on all categories of layer farms. But the small layer farms were highly sensitive to increase in costs and decrease in net returns followed by medium farms. On the basis of NPV, BCR and IRR, investment in layer farming was found to be most profitable in large farms followed by medium and small farms. This was due to the fact that the benefits per bird were highest and cost of production was lowest on large farms. In contrast, the benefits per bird were lowest and cost per bird was highest on small farms. These results are in agreement with the results of financial analysis reported by Singh et al [4].

## 4. CONCLUSION

The Net Present Worth is highest for large farms followed by medium and small farms at both discount rates which in turn prove the economic viability of farms. The Benefit-Cost Ratio was positively related with farm-size and the large farms were economically more viable. The internal rate of return is higher than that of the discount rate for all sizes of farms which implies that investment is feasible. Even though the returns are decreased by 10% (Case I) or Costs increased by 10% (Case II) the small, medium and large poultry layer farms are economically feasible at both 12% and 16% discount rates as NPV is positive and BCR is greater than 1. But if the returns are decreased by 10% and Costs increased by 10% (Case III) the small farms become financially infeasible at both discount rates whereas medium farms become financially infeasible at 16% discount rate only. The large layer farms are economically feasible at both discount rates if the returns are decreased by 10% and Costs increased by 10% (Case III). Based on NPV, BCR and IRR, large layer farms were most profitable followed by medium and small layer farms. The benefits per bird were highest and cost of production was lowest in case of large farms. Thus, poultry layer farming is a profitable business and there is still scope for its growth due to increase in demand for poultry products.
